PD-L2 modulates asthma severity by directly decreasing dendritic cell IL-12 production

Studies examining the role of programmed death 1 (PD-1) ligand 2 (PD-L2)/PD-1 in asthma have yielded conflicting results. To clarify its role, we examined the PD-L2 expression in biopsies from human asthmatics and the lungs of aeroallergen-treated mice. PD-L2 expression in bronchial biopsies correlated with the severity of asthma. In mice, allergen exposure increased PD-L2 expression on pulmonary myeloid dendritic cells (DCs), and PD-L2 blockade diminished allergen-induced airway hyperresponsiveness (AHR). By contrast, PD-1 blockade had no impact, suggesting that PD-L2 promotes AHR in a PD-1-independent manner. Decreased AHR was associated with enhanced serum interleukin (IL)-12 p40, and in vitro stimulation of DCs with allergen and PD-L2-Fc reduced IL-12 p70 production, suggesting that PD-L2 inhibits allergen-driven IL-12 production. In our model, IL-12 did not diminish T helper type 2 responses but rather directly antagonized IL-13-inducible gene expression, highlighting a novel role for IL-12 in regulation of IL-13 signaling. Thus, allergen-driven enhancement of PD-L2 signaling through a PD-1-independent mechanism limits IL-12 secretion, exacerbating AHR.

INTRODUCTION

Allergic asthma is an inflammatory lung disease whose prevalence continues to rise in developed nations. Although the origins of allergic asthma are complex, excessive activation of T helper type 2 (Th2) cells specific for normally innocuous environmental allergens drives disease pathology. Thus, in asthmatic individuals, allergen exposure triggers the development of allergen-specific Th2 cells producing interleukin (IL)-4, IL-5, and IL-13, which induce immunoglobulin E (IgE), eosinophilia, mucus hypersecretion, and airway hyperresponsiveness (AHR).1 By contrast, non-asthmatic individuals develop protective responses mediated by IL-10 and transforming growth factor-β secreting regulatory T cells.2,3 Thus, the type of T-cell response induced following allergen exposure is an important determinant of susceptibility to allergen-induced AHR.

In vivo, dendritic cells (DCs) represent the most potent professional antigen-presenting cells in the lung, and they have been identified as key players in promoting both pathogenic or protective T-cell responses.4 In the lung, DCs lie immediately below the epithelial cell layer and extend their dendrites into the lumen, capture inhaled allergens, and then migrate to lung-draining lymph nodes where they present captured allergens to naive T cells.5,6 Many factors influence the ability of DCs to promote pathogenic vs. protective T-cell responses. Allergen presentation by myeloid DCs (mDCs) promotes both initiation of AHR in naive animals4,7 and exacerbations in previously sensitized animals,8 whereas allergen presentation by plasmacytoid DCs prevents the initiation of AHR8 and limits allergic inflammation in previously sensitized hosts.9 DCs also influence the development of allergen-induced AHR through production of T-cell skewing cytokines. We have recently demonstrated that the production of high levels of IL-23 by pulmonary mDCs is associated with the development of a mixed Th2/Th17 cytokine profile that ultimately results in the development of severe AHR.4,10 By contrast, the development of weak AHR observed in C3H/HeJ mice is associated with the production of IL-12,11 and administration of exogenous IL-12...
limits the severity of AHR in asthma-susceptible A/J animals.\textsuperscript{12} Finally, the types of co-stimulatory molecules expressed by DCs also control T-cell development such that expression of CD80, CD86, and OX40L all promote allergic disease,\textsuperscript{13–15} while ICOS-L (inducible costimulatory ligand) expression induces the development of regulatory T cells and promotes inhalational tolerance.\textsuperscript{16} Thus, by virtue of the subsets of DCs involved in allergen presentation and the nature of the cytokines or co-stimulatory molecules produced, DCs regulate the development of pathogenic vs. protective T-cell responses.

Another way DCs regulate T-cell responses is through expression of programmed death 1 (PD-1) family members. The PD-1 family consists of PD-1 ligand 1 (PD-L1; found on DCs, T cells, B cells, and structural cells),\textsuperscript{17,18} PD-L2 (expressed on DCs and macrophages)\textsuperscript{18} and PD-1 (expressed on T cells, DCs and macrophages).\textsuperscript{19–21} In general, stimulation of T cells through PD-1 or PD-L1 limits CD3-mediated activation of T cells. Indeed, PD-1 stimulation is responsible for the T-cell “exhaustion” observed in models of chronic viral infection (lymphocytic choriomeningitis virus, HIV).\textsuperscript{22,23} contributes to allograft tolerance,\textsuperscript{24} and prevents autoimmune disease.\textsuperscript{17,25}

Interestingly, despite the generally inhibitory role for PD-1 in regulating T-cell activation, the role of the PD-1/PD-L axis in regulating allergic asthma is uncertain, with some reports suggesting a protective role for this pathway,\textsuperscript{9,26–29} and others reporting a pro-asthmatic role for either PD-L1\textsuperscript{27} or PD-L2.\textsuperscript{30}

Herein, we sought to clarify the role of PD-L2 in allergen-induced AHR. We demonstrate that in both mice and humans, increased PD-L2 expression is associated with more severe AHR. Supporting a role for a PD-L2 in modulating asthma severity, in vivo blockade of PD-L2 reduces the severity of allergen-driven AHR. Surprisingly, PD-L2 blockade does not alter the production of Th2 cytokines, the composition of inflammatory cells in the bronchoalveolar lavage (BAL), or synthesis of IgE, but rather, enhances the ability of DCs to secrete IL-12 p70, and simultaneous blockade of both PD-L2 and IL-12 abrogate the protective effects observed upon blockade of PD-L2 alone. Strikingly, blockade of PD-1 had no impact on AHR or systemic IL-12 levels, suggesting that PD-L2 regulates asthma severity in a PD-1-independent manner. Furthermore, in our model, increased IL-12 production is not associated with decreased Th2 cytokine production. However, we demonstrate that IL-12 directly antagonizes IL-13-driven gene induction and STAT6 (signal transducer and activator of transcription factor 6) phosphorylation, providing a mechanism whereby IL-12 may limit the severity of allergen-induced AHR. Collectively, these results demonstrate that PD-L2, through an unknown receptor, limits IL-12 secretion, thereby enhancing the magnitude of allergen-induced AHR.

**RESULTS**

**mDC expression of PD-L2 is associated with ongoing AHR**

In this study, we sought to clarify the role of PD-L2 in asthma. To this end, we compared PD-L2 expression in the lung following sequences of allergen exposures designed to induce either robust AHR, or the development of tolerance. As such, we exposed mice to house-dust mite (HDM) extract intratracheally (IT) on days 0 and 14, a protocol previously shown to induce robust AHR in A/J mice.\textsuperscript{4} As expected, HDM exposure induced robust AHR (Figure 1a) as measured by monitoring airway pressure changes over time, as described elsewhere.\textsuperscript{31}

We then examined PD-L2 messenger-RNA expression in the lungs of mice at 2, 24, or 72 h after the last IT challenge. PD-L2 expression was upregulated by HDM at 2 h and peaked 24 h later (Figure 1b). To determine whether PD-L2 induction was unique to HDM, A/J mice were sensitized intraperitoneally (IP) with ovalbumin (OVA) in saline on day 0 and challenged IT with OVA on days 14 and 21. As previously reported,\textsuperscript{11} this treatment regimen induced AHR (Figure 1a). As with HDM, OVA exposure also induced a rapid increase in PD-L2 expression that peaked at 24 h (Figure 1b). Interestingly, despite an identical number of allergen exposures, mice receiving OVA exclusively IT, a regimen known to induce tolerance rather than AHR,\textsuperscript{8,16} demonstrated no induction of AHR (Figure 1a) and failed to upregulate PD-L2 expression significantly, suggesting that enhanced PD-L2 expression is associated with allergen-induced AHR (Figure 1b).

PD-L2 is chiefly expressed by antigen-presenting cells,\textsuperscript{18} however, multiple pulmonary DC populations have been described to date. To determine whether PD-L2 was differentially expressed on different DC subsets, mice were treated IT with HDM on day 0 and fluorescent HDM (AF405-HDM) on day 14 to facilitate the identification of allergen-bearing DCs by flow cytometry. Seventy-two hours after HDM exposure, five distinct populations of CD11c\textsuperscript{+} cells could be identified by flow cytometry, including alveolar macrophages, plasmacytoid DCs, neutrophils, inflammatory DCs, and mDCs (see Supplementary Figure S1a online). Although alveolar macrophages demonstrated some allergen uptake, and alveolar macrophages, neutrophils, and inflammatory DCs all expressed some PD-L2 after allergen challenge, mDCs were the only population simultaneously positive for both AF405-HDM and PD-L2 (see Supplementary Figure S1b online). Thus, HDM\textsuperscript{+}PD-L2\textsuperscript{+} mDCs represented up to \(\sim 15\%\) of all mDCs found in the lung, while the increase in the frequency of other HDM\textsuperscript{+}PD-L2\textsuperscript{+} DC populations was comparatively minor (\(\leq 3\%\)) (Figure 1c). Moreover, the levels of PD-L2 expression (as measured by mean fluorescence intensity) increased markedly on pulmonary mDCs after allergen exposures (Figure 1d). By contrast, the mean fluorescence intensity of PD-L2 expression was not significantly increased on other pulmonary DC populations (Figure 1d). These data suggest that pulmonary mDCs are the principal PD-L2-expressing DC subset in the lung.

To determine whether a similar association between PD-L2 expression and increased asthma severity is present in human populations, we compared PD-L2 expression in bronchial biopsies from patients with mild asthma, severe asthma, and healthy control subjects. PD-L2 expression was undetectable in healthy control subjects (Figure 1e). In comparison to healthy controls, the expression of PD-L2 was enhanced in patients...
Programmed death-1 ligand 2 (PD-L2) expression is enhanced in the airways of asthmatic individuals and allergen-exposed mice. Mice were treated with phosphate-buffered saline (PBS—intratraecheally (IT) on days 0 and 14), IT ovalbumin (OVA IT – 100 μg on days 0, 14, and 21), intraperitoneal (IP)/IT OVA (OVA IP/IT – 10 μg OVA IP on day 0 followed by 100 μg IT on days 14 and 21), or IT house-dust mite (HDM – 100 μg on days 0 and 14). (a) Mice were killed 72 h after final allergen exposure to measure airway hyperresponsiveness via the airway pressure time index (APTI) method. (b) PD-L2 expression (normalized to mouse ribosomal protein S14) was measured by real-time PCR. n = 4 mice per group. One representative experiment of two shown. Mean + s.e.m. are shown. ***P < 0.001 and **P < 0.01 vs. PBS-treated mice. (c) The frequency of HDM + dendritic cells (DCs) of the indicated subsets expressing PD-L2 and (d) the mean fluorescent intensity (MFI) of PD-L2 expression on the total DC population (regardless of allergen uptake) was assessed by flow cytometry. n = 4 mice per group. Mean + s.e.m. are shown. ***P < 0.001 vs. PBS-treated mice. One representative experiment of two shown. (e) PD-L2 expression (normalized to human ribosomal protein S9) was assessed by PCR in samples taken from normal controls or individuals categorized as mild or severe asthmatics. Each point represents a single individual. AM, alveolar macrophages; inf, inflammatory; mdc, myeloid dendritic cell; pDC, plasmacytoid dendritic cell; PMN, polymorphonuclear leukocytes.

PD-L2 blockade limits the development of allergen-induced AHR

To directly assess the role of PD-L2 in AHR in mice, we examined the effect of a PD-L2-blocking monoclonal antibody (mAb; clone TY25) on the development of allergen-induced AHR. As expected, HDM increased AHR, which was not impacted by an isotype control mAb (Figure 2a). By contrast, administration of anti-PD-L2 significantly reduced the development of HDM-induced AHR, demonstrating that PD-L2 modulates asthma severity (Figure 2a). Although PD-L2 is a ligand for PD-1, some reports suggest that PD-L2 can bind a receptor other than PD-1. To determine whether PD-L2 enhances asthma through interactions with PD-1, we examined the impact of PD-1 blockade on the development of AHR. However, treatment with a mAb known to block interactions between PD-1 and both of its known ligands (PD-L1 and PD-L2; clone RMPI-14) had no impact on the magnitude of HDM-induced AHR in A/J animals (Figure 2b). This suggests that PD-L2 regulates the severity of AHR through a PD-1-independent mechanism.

As airway inflammation is a hallmark of allergen-induced asthma, we also examined the cells present in the BAL of mice following exposure to phosphate-buffered saline (PBS), HDM, HDM + isotype control mAb, or HDM + anti-PD-L2. We harvested BAL at the time of killing and performed differential cell counts. As expected, HDM exposure induced the recruitment of significant numbers of macrophages, eosinophils, neutrophils, and lymphocytes (Figure 3a). However, the BAL cell profile was unaffected by either the presence of control mAb, anti-PD-L2 (Figure 3a) or anti-PD-1 (data not shown).
Moreover, analysis of BAL cytokine levels demonstrated that although HDM increased the amounts of IL-4, IL-5, and IL-13 found in the BAL fluid, the levels of these cytokines were not significantly impacted by administration of isotype control or PD-L2-blocking mAbs (Figure 3b). To further characterize the immune response, we also examined HDM-stimulated cytokine production in lung cell cultures from mice treated in vivo with anti-PD-L2 or a control mAb. As previously shown, HDM-treated A/J mice display a mixed Th2/Th17 cytokine profile, with robust production of IL-4, IL-5, IL-13, and IL-17A (Figure 3c-f) but no interferon (IFN)-γ (data not shown). However, we observed no impact of in vivo anti-PD-L2 treatment on the production of any of the cytokines examined. Consistent with unaltered T-cell cytokine production or BAL cell recruitment, the activation status of pulmonary mDCs was also unaltered in mice treated with anti-PD-L2 (see Supplementary Figure S2 online). Thus, in our model, endogenous expression of PD-L2 appears to regulate the severity of allergen-induced AHR, but not by amplifying the intensity of the underlying Th2 or Th17 responses.

**PD-L2 blockade significantly reduces airway mucus, whereas enhancing IgG2a production and systemic IL-12 p40 levels**

As mucus hypersecretion is also a hallmark of allergic asthma, we assessed mucus production in the lungs of mice treated with PD-L2-blocking Ab. As expected, compared with mice treated with PBS, those treated with HDM + isotype demonstrated markedly higher numbers of epithelial cells that stained with PAS (periodic acid-Schiff; Figure 4a). By contrast, treatment of HDM-exposed mice with anti-PD-L2 significantly decreased the number of PAS+ epithelial cells (Figure 4a). To further characterize the immune response in HDM + anti-PD-L2-treated A/J mice, we assessed serum Ig levels. HDM exposure induced increased total IgE (Figure 4b; as a surrogate for allergen-specific IgE activity), HDM-specific IgG1 (Figure 4c), and HDM-specific IgG2a (Figure 4d), but treatment with control mAb had no impact on serum Ig levels. Although PD-L2 blockade did not alter IgE or IgG1 production, it nearly doubled the levels of HDM-specific IgG2a. As IgG2a production is driven by Th1-associated cytokines, we examined the levels of IL-12 p40 in the serum (Figure 4e). IL-12 p40 levels in the serum were significantly enhanced in HDM + anti-PD-L2 treated mice, suggesting that PD-L2 can limit IL-12 p40 levels (Figure 4f). Interestingly, a similar increase was not observed in BAL, where IL-12 p40 levels were unaffected by anti-PD-L2 treatment (see Supplementary Figure S3 online). As increases in systemic IL-12 levels limit the development of allergen-induced AHR in A/J mice, the increase in serum IL-12 p40 may explain the decreased AHR observed in anti-PD-L2-treated mice.

**IL-12 blockade abrogates the protective effect of anti-PD-L2 treatment**

To specifically test the hypothesis that increased IL-12 levels observed following PD-L2 blockade are responsible for decreased AHR, we treated mice with HDM in the presence of isotype control mAbs, HDM+ anti-PD-L2, HDM + anti-IL-12, or HDM + anti-PD-L2 + anti-IL-12. Although treatment of A/J mice with anti-IL-12 had no impact on AHR, treatment of mice with anti-PD-L2 significantly diminished AHR
However, treatment with anti-IL-12 abrogated the protective effect of PD-L2 blockade, as AHR in mice treated simultaneously with anti-PD-L2 and anti-IL-12 was indistinguishable from mice treated with isotype control mAbs alone (Figure 5a). Baseline AHR measurements (taken before injection of acetylcholine) demonstrated that although HDM increased basal AHR, this was not significantly different among the treatment groups (see Supplementary Figure S4 online).

Examination of HDM-restimulated cytokine production in lung cell cultures from anti-PD-L2, anti-IL-12, or anti-PD-L2 + anti-IL-12-treated mice revealed that although HDM induced production of both Th2 (IL-4, IL-5, and IL-13; Figure 5b–d) and Th17 (IL-17A; Figure 5e) cytokines, there was no difference between the treatment groups. Similar results were observed when IL-5 and IL-13 expression levels were assessed by RT-PCR in samples taken from the lung immediately after sacrifice (see Supplementary Figure S5 online).

**PD-L2 stimulation inhibits allergen-induced IL-12 production**

As IL-12 p40 is a component of both bioactive IL-12 p70 and IL-23, which may have opposing effects on the development of allergen-induced AHR, we next determined whether changes in IL-12 p40 observed following PD-L2 blockade were due to specific effects on IL-12 p70 or IL-23. To this end, we cultured bone marrow–derived mDCs (BMDCs) with HDM on plates coated with PD-L2-Fc, PD-L1-Fc, or a control IgG-Fc. HDM induced IL-12 p70 production from BMDCs, and this production was unaltered by IgG-Fc (Figure 6a). DCs cultured on PD-L2-Fc-coated plates produced significantly less IL-12 p70 (Figure 6a), suggesting that stimulation with PD-L2-Fc can limit HDM-induced IL-12 p70 production. By contrast, stimulation of DCs with HDM in the presence of PD-L1-Fc, an alternative ligand for PD-1, did not impair IL-12 p70 production, suggesting that PD-1 signaling is not regulating IL-12 production. The inhibition was specific for IL-12, as stimulation with PD-L2-Fc did not alter HDM-induced secretion of other DC-derived cytokines IL-23, IL-6, TNF-α (Figure 6b–d), or IL-10 (data not shown). To directly test whether the capacity of PD-L2 signaling to limit bioactive IL-12 production was independent of PD-1, we cultured BMDCs on plates coated with either rIgG-Fc or PD-L2-Fc and stimulated these cells in the presence of anti-PD-1. As shown in Figure 6e, HDM-stimulated BMDCs plated on PD-L2-coated plates...
Simultaneous neutralization of endogenous interleukin (IL)-12 reverses decreased airway hyperresponsiveness (AHR) observed following programmed death-1 ligand 2 (PD-L2) blockade. A/J mice were treated with phosphate-buffered saline (PBS) or house-dust mite (HDM) intratracheally on days 0 and 14. Mice were given 250 μg of rat IgG2a (immunoglobulin G2a) control (Iso) or anti-PD-L2 (αPD-L2) IP on days 0, 2, 14, and 16 and/or 1 mg of rat IgG2a control (Iso) or anti-IL-12 (αIL-12) IP on days -2 and 12. Mice were sacrificed on day 17 for assessment of AHR by the airway pressure time index (APTI) method. Lung cells were re-stimulated in vitro with HDM and levels of (a) IL-4, (b) IL-5, (c) IL-13, and (e) IL-17A were assessed by enzyme-linked immunosorbent assay. n = 10 mice from two independent experiments. Mean ± s.e.m. are shown. *P < 0.05 compared with anti-PD-L2/Iso-treated mice.

Stimulation of bone marrow–derived myeloid dendritic cells (BMDCs) with programmed death-1 ligand 2 (PD-L2)-Fc limits house-dust mite (HDM)-induced interleukin (IL)-12 p70, but not IL-23, IL-6, or tumor-necrosis factor α (TNFα) production. BMDCs were grown as described in Materials and Methods. Cells were cultured in the presence of medium alone (Med) or HDM on plates coated with immunoglobulin G (IgG)-Fc, PD-L2-Fc, or PD-L1-Fc. After 18 h, supernatants were harvested, and the levels of (a) IL-12 p70, (b) IL-23, (c) IL-6, and (d) TNFα were determined by enzyme-linked immunosorbent assay (ELISA). n = 17 individual wells, over three independent experiments. Mean ± s.e.m. are shown. **P < 0.01 vs. HDM + IgG-Fc-stimulated wells. BMDCs were cultured on plates coated with phosphate-buffered saline (open bars), IgG-Fc (gray bars), or PD-L2-Fc (black bars) in the presence of (e) HDM or (f) lipopolysaccharide (LPS) in the presence or absence of anti-PD-1. After 18 h, supernatants were harvested and the levels of IL-12 p70 were determined by ELISA. n = 4 wells from one of two experiments were performed. Mean ± s.e.m. are shown. *P < 0.05 and **P < 0.01.
produced less IL-12 p70, and their overall production of IL-12 p70 was not affected by the presence of PD-1-blocking mAb. Similar results were observed when cells were stimulated with lipopolysaccharide (LPS; Figure 6f). Thus, stimulation with PD-L2 appears to specifically limit the capacity of DCS to secrete IL-12 p70 through a PD-1-independent mechanism.

IL-12 directly antagonizes IL-13-induced gene expression

Our observation that enhanced IL-12 production was associated with diminished AHR and mucus secretion, but unaltered production of IL-4, IL-5, IL-13, and IL-17A suggests that IL-12 may be regulating the severity of AHR by directly antagonizing signaling initiated by Th2 cytokines. As IL-13 has a major role in both allergen-induced AHR and mucus secretion, we tested the hypothesis that IL-12 was antagonizing IL-13 signaling. To this end, BMDCs were cultured with medium, IL-12, IL-13, or IL-12 + IL-13, and phosphorylation of STAT6, a signaling intermediate directly activated as a result of IL-13R engagement, was measured by western blot. As shown in Figure 7a, no detectable STAT6 phosphorylation was observed in medium or IL-12-stimulated BMDC cultures, whereas IL-13 induced robustSTAT6 phosphorylation. In the presence of IL-12, IL-13-induced STAT6 phosphorylation was reduced but not completely abrogated (Figure 7a).

To confirm that the reduced STAT6 phosphorylation observed in IL-12 + IL-13-stimulated BMDC cultures was biologically significant, we subsequently examined the impact of IL-12 exposure on the expression of IL-13-driven genes by real-time (RT)–PCR. Although IL-13 induced the expression of FIZZ1, Arg1, and CD206 in BMDCs (Figure 7b) the induction of these genes was reduced following co-culture with IL-12 (Figure 7b). As reported elsewhere, IL-13 also induced the expression of PD-L2 on BMDCs. Interestingly, IL-13-driven PD-L2 expression was similarly inhibited in the presence of IL-12, suggesting that IL-12 may support its own production by antagonizing IL-13-driven PD-L2 expression. Not all IL-13-driven genes were inhibited to the same extent, as IL-12 completely abrogated CD206 expression, whereas effects on other IL-13-driven genes (Arg1, Fizz1, PD-L2) were only partially abrogated, consistent with reduced, but not abrogated, phosphorylation of STAT6 observed in Figure 6a. By contrast, although IL-12 increased IFN-γ expression in A/J BMDCs, this was not antagonized by IL-13, suggesting that IL-13 may not antagonize IL-12 signaling (see Supplementary Figure S6a).

Moreover, other Th1 cytokines can have a similar impact, as co-culture of BMDCs with IFN-γ and IL-13 also abrogated IL-13-driven gene expression (see Supplementary Figure S6b). In contrast to the inability of IL-13 to inhibit IL-12-driven genes, IL-13 strongly inhibited the induction of an IFN-γ-driven gene (PD-L1; see Supplementary Figure S6b).

As IL-12 is widely known as an inducer of IFN-γ, we also determined whether the inhibition of IL-13 signaling by IL-12 was mediated by IFN-γ, through the blockade of IFN-γ in cultures of BMDCs treated with IL-12 and IL-13. Inhibition of IL-13-induced Fizz1 expression by IL-12 was completely reversed by addition of anti-IFN-γ (see Supplementary Figure S6c online). However, it is unlikely that the effects of IL-12 on IL-13 signaling were entirely dependent upon induction of IFN-γ, as IL-12-mediated inhibition of STAT6 phosphorylation was observed as little as 15 min after IL-13 stimulation (too rapid to be due to de novo IFN-γ synthesis) (Figure 7a), and IFN-γ blockade did not restore the expression of Arg1 or CD206 to levels seen in the absence of IL-12 (see Supplementary Figure S6c online).

DISCUSSION

In this study, we have examined the role of the co-stimulatory molecule, PD-L2, in the development of allergen-induced AHR. We find that PD-L2 is upregulated in the lungs of individuals with severe (but not mild) asthma and in allergen-exposed mice. In contrast to current dogma, which would suggest an inhibitory role for PD-L2 based on interactions with PD-1, in vivo PD-L2 blockade reduces allergen-induced AHR. Although PD-L2 blockade reduced AHR, no significant impact on eosinophilia, IgE synthesis, or pulmonary DC activation was observed, suggesting that PD-L2 regulates AHR without impacting other features of allergic asthma. Collectively, these data suggest that PD-L2 expression regulates the overall magnitude of AHR in allergic asthma.

Our observation that PD-L2 signaling exacerbates asthma severity is in agreement with the previous report that PD-L2-Fc treatment enhances pulmonary inflammation in OVA (alum)-sensitized BALB/c mice. However, in contrast to our results, it has also been reported that blockade of PD-L2 (but not PD-1) in OVA (alum)-sensitized BALB/c mice triggers increased AHR, a phenotype that was blocked with co-administration of IFN-γ-blocking antibodies. Similarly, AHR induced by exposure of BALB/c mice to OVA (alum) or αGalCer was increased in PD-L2-deficient mice due to increased IL-4 production by inducible natural killer T cells. Although these reports appear to conflict with our own, both are consistent with an increase in IL-12 production in the absence of PD-L2 signaling. In the study by Matsumoto et al., although IL-12 levels were not assessed, it is likely that the IFN-γ-driven increased AHR...
following PD-L2 blockade was driven by enhanced IL-12 production triggered by the lack of PD-L2 signaling. Moreover, IL-12 has been shown to drive IL-4 production in inducible natural killer T cells. Thus, PD-L2−/− mice lack a negative regulator of IL-12 production, inducible natural killer T cells from these mice display increased production of IL-4. Thus, collectively these studies support an important role for PD-L2 in the direct regulation of IL-12 synthesis.

Although IL-12 is classically regarded as a shaper of adaptive immunity, we find that the enhancement of IL-12 production observed following PD-L2 blockade does not regulate the balance of Th1- and Th2-associated cytokines in our model. It should be noted that although we observe robust PD-L2 expression after allergen challenge, we observe very few PD-L2+ mDCs immediately after a single allergen inhalation (data not shown). This suggests that the elevated IL-12

Figure 7  Interleukin (IL)-12 directly antagonizes IL-13-induced STAT6 (signal transducer and activator of transcription factor 6) phosphorylation and gene expression. Bone marrow–derived myeloid dendritic cells (BMDCs) were stimulated with medium alone (Med), IL-12 (10 ng ml⁻¹), IL-13 (10 ng ml⁻¹), or a combination of IL-12 + IL-13 for 15 min. Proteins were separated on a sodium dodecyl sulfate gel and transferred to a PVDF membrane for detection of (a) pSTAT6, total STAT6, and as a loading control, α-tubulin. BMDCs were stimulated with medium alone, IL-12 (10 ng ml⁻¹), IL-13 (10 ng ml⁻¹), or a combination of IL-12 + IL-13 for 18 h. Messenger-RNA was harvested from the cell, and the expression of IL-13-driven genes was examined by real-time (RT-PCR). (b) Primary murine tracheal epithelial cells (mTECs) from C57Bl/6 mice were treated with medium alone, IL-12 (10 ng ml⁻¹), IL-13 (10 ng ml⁻¹), or IL-12 + IL-13 (both at 10 ng ml⁻¹) for 24 h. RNA was isolated, and the expression of IL-13-driven genes was examined by RT-PCR. Mean ± s.e.m. are shown. *P < 0.05 and **P < 0.01 vs. IL-13-treated cultures. n = 4 replicates for each condition tested. PD-L2, programmed death-1 ligand 2.
observed following anti-PD-L2 treatment is likely only present during the effector phase, after allergen challenge. Thus, by inhibiting IL-12 levels exclusively during the effector phase, we find that PD-L2 directly promotes IL-13-driven sequelae (AHR, mucus hypersecretion) in allergic asthma independently of its effects on T-cell differentiation. Although it is conceivable that blockade of PD-L2 induces other changes which may contribute to the reduced AHR observed, simultaneous blockade of PD-L2 and IL-12 abrogates the protective effects of PD-L2 blockade, suggesting that the increased IL-12 observed is the dominant influence on the reduced AHR observed following PD-L2 blockade.

Although the precise gene products induced by IL-13 that promote the development of AHR are not clear, we have demonstrated that IL-12 can inhibit a number of IL-13-induced products with described roles in allergic asthma. In BMDCs, IL-12 inhibits IL-13-induced expression of Fizz1 and Arg1, products associated with alternatively activated macrophages, which have been shown to have a pathogenic role in allergic asthma.42,43 Additionally, IL-12 also antagonized the IL-13-induced expression of CD206 (a receptor shown to promote the phagocytosis of Derp1) in BMDCs. Although we do not observe an increase in overall HDM uptake by pulmonary DCs following blockade of PD-L2 in vivo, it is possible that PD-L2 blockade may subtly regulate the ability of DCs to take up or present specific allergenic peptides. In primary murine tracheal epithelial cells, IL-12 also inhibited the IL-13-induced expression of the genes encoding IL-33, (a Th2-inducing cytokine), AMCase (capable of enhancing allergen-driven IL-13 production), and Fizz1 (capable of inducing airway eosinophilia and airway remodeling).46 We also see reduced IL-13-driven expression of Sprr2b following IL-12 treatment.

Although little is known about the role of Sprr2b in the development of allergic asthma, it is induced by IL-13 but not IL-4.46 This is of particular interest as IL-13 is considerably more important than IL-4 in the induction of AHR, suggesting that gene products induced by IL-13, but not IL-4, may have an important role in promoting AHR. Finally, we also demonstrate that IL-12 can directly antagonize STAT6 phosphorylation triggered by IL-13. It is likely that this effect may directly contribute to the reduced AHR observed in mice treated with anti-PD-L2 as STAT6 activation is critically required to trigger IL-13-induced AHR. Thus, despite unaltered levels of overall IL-13 production, IL-12 may impact the overall bioactivity of IL-13 through a number of different mechanisms.

That IL-12 may directly antagonize IL-13 signaling is also consistent with our previous observation that IL-12 blockade in A/J mice enhanced basal acetylcholine-induced airway constriction, suggesting that IL-12 can regulate airway tone in the absence of airway inflammation, and with reports showing IL-12-deficient mice can display enhanced AHR, with minimal impact on Th2 cytokine production. We also find elevated PD-L2 expression in individuals with severe asthma but not those suffering from milder forms of disease, suggesting that PD-L2 expression may also be correlated with asthma severity in humans as well. Although we did not examine IL-12 levels in individuals with severe vs. mild asthma, Morahan et al. have shown that a combination of single nucleotide polymorphisms in the human IL-12 p40 promoter, resulting in reduced LPS-stimulated IL-12 p40 secretion by peripheral blood mononuclear cells, is associated with more severe asthma, regardless of the atopic status of the individual.

This suggests that impaired IL-12 production in humans also correlates with asthma severity but not T-cell skewing leading to initial sensitization (i.e., atopic status). Thus, our study highlights a previously underappreciated role of IL-12 in directly limiting asthma severity.

PD-L2 is typically thought to signal through PD-1 providing an inhibitory signal, limiting proliferation, and cytokine production of both T cells and antigen-presenting cells. However, interactions between PD-L2 and a receptor other than PD-1 were observed in a number of in vitro studies where it was demonstrated that such interactions enhance T-cell activity. Multiple lines of evidence suggest that, in our model, the dominant signals provided by PD-L2 are mediated by a non-PD-1 receptor including: (1) in vivo blockade of PD-L2 and PD-1 have differential impacts on HDM-induced AHR, (2) stimulation with PD-L2, but not PD-L1, limits HDM- and LPS-induced IL-12 production in vitro, and (3) the ability of PD-L2 to inhibit HDM or LPS-driven IL-12 p70 production in BMDCs is not abrogated in the presence of antibodies known to block the interactions between PD-L2 and PD-1. As stimulation of DCs with IL-12, but not PD-L1, limits HDM-induced IL-12 production, we speculate that DCs also express the unidentified PD-L2 receptor and that signaling through this receptor in DCs directly regulates IL-12 p70 production. Intriguingly, as PD-L2 is primarily expressed by mDCs, the ability of PD-L2 to downregulate DC-derived IL-12 production suggests that autocrine or paracrine interactions between DCs are capable of regulating IL-12 production. Thus, PD-L2-mediated regulation of immune responses is complex, being regulated via interactions between PD-L2 and at least two distinct receptors, both of which are expressed on DCs and T cells, and which have distinct effects based on the types of cells studied. Such complexities suggest that PD-L2 (and other family members) acts as a rheostat, modulating the responsiveness to immune mediators such as IL-13, rather than providing an “on/off” switch for one particular type of response. However, our observation of differential expression levels of PD-L2 in human tissues taken from individuals with mild vs. severe asthma suggest that these subtle influences can have a substantial impact on disease severity.

Collectively, these data demonstrate that PD-L2 expression modulates the overall magnitude of AHR in allergic asthma. However, rather than directly regulating T-cell activity through interactions with its previously described receptor, PD-1, the dominant function of PD-L2 in vivo is inhibition of antigen-presenting cell–derived IL-12 through interactions with an unknown receptor. Moreover, PD-L2 stimulation of purified DCs directly inhibits IL-12 production, demonstrating that the
unknown receptor is also expressed by DCs and suggesting that DC:DC interactions, either autocrine or paracrine, modulate IL-12 synthesis in vivo. Finally, these data also demonstrate that IL-12 can directly antagonize IL-13-driven gene transcription, highlighting a previously unappreciated role for IL-12 in modulating the activity of Th2 effector cytokines. Thus, in asthmatics, increased PD-L2 expression in the inflamed lung downregulates IL-12 secretion, facilitating greater IL-13 responsiveness and allowing the development of more severe AHR.

METHODS

Mice. Male A/J mice were purchased from Jackson Laboratories (Bar Harbor, ME) at 4 weeks of age and housed in a specific pathogen-free facility at Cincinnati Children's Hospital Medical Center. Experiments were initiated at 6 weeks of age. Animal experiments were approved by the CCHMC Institutional Animal Care and Use Committee.

Treatment protocols. Mice were treated with 40 µl PBS, HDM (100 µg; Greer Laboratories, Lenoir, NC), or AlexaFluor405-labeled (Invitrogen, Carlsbad, CA) HDM (AF405-HDM) IT on days 0 and 14. Where indicated, mice were treated with low-endotoxin OVA (Worthington Biochemicals, Lakewood, NJ) to induce AHR (10 µg IP on day 0 and 100 µg IT on days 14 and 21) or tolerance (100 µg IT on days 0, 14, and 21). Mice were treated IP with 250 µg anti-IL-12 (TY25.16.13), anti-IL-13 (RMP1-14), or control rat IgG2a (GL117) 6 h before and 48 h following each allergen exposure. Where indicated, mice were also treated with 1 mg of anti-IL-12 (clone C17.8, a gift of Dr. Fred Finkelman, University of Cincinnati) or control rat IgG2a (GL117) on days −2 and 12.

Assessment of allergen-induced AHR. AHR was measured by assessing changes in tracheal pressure following administration of a cholinergic agonist over time and expressed as the airway pressure time index and is described in detail elsewhere. Importantly, this parameter has been shown to provide data similar to Flexivent-derived data generated using a full-dose response of inhaled methacholine. Importantly, this parameter has been shown to provide data similar to Flexivent-derived data generated using a full-dose response of inhaled methacholine.61 Importantly, this parameter has been shown to provide data similar to Flexivent-derived data generated using a full-dose response of inhaled methacholine.61

To evaluate AHR, mice were anaesthetized, intubated, and respirated at a rate of 120 breaths per minute with a constant tidal volume (0.2 ml) for 5 min. Blood was collected to measure total IgE and index and is described in detail elsewhere.31 Importantly, this parameter has been shown to provide data similar to Flexivent-derived data generated using a full-dose response of inhaled methacholine.61

Where indicated, lungs were lavaged with Hank’s Balanced Salt Solution (Invitrogen). Cells were recovered by centrifugation and total cells counted. Slides were prepared by cytospin and stained with Diff-Quik (Dade Behring, Düdingen, Switzerland) for differential cell counts.

Lung cell isolation. After AHR measurements, lungs were removed, minced, and placed in 6 ml of RPMI 1640 containing Liberase Cl (0.5 mg ml−1; Roche Diagnostics, Indianapolis, IN) and DNase I (0.5 mg ml−1; Sigma, St Louis, MO) at 37 °C for 45 min. The remaining tissue was forced through a 70-micron cell strainer, and red blood cells were lysed with ACK (ammonium chloride-potassium) lysis buffer (Invitrogen). Cells were washed with RPMI containing 10% fetal bovine serum FBS, viable cells were counted via trypan blue exclusion. Where indicated, lung cells were cultured at 350,000 cells per well of a 96-well plate (250 µl final volume) with HDM (30 µg ml−1); Tissue culture supernatants were harvested at 72 h.

Flow cytometry. Staining reactions were performed at 4 °C following incubation with FcBlock (mAb 2.4G2) for 30 min. Alveolar macrophages (CD11c<sup>bright</sup>CD11b<sup>dim</sup>CD31<sup>−</sup>CD103<sup>+</sup>), neutrophils (CD11c<sup>bright</sup>CD11b<sup>−</sup>CD31<sup>−</sup>CD103<sup>−</sup>), inflammatory DCs (CD11c<sup>bright</sup>CD11<sup>−</sup>CD31<sup>−</sup>CD103<sup>−</sup>), and mDCs (CD11c<sup>−</sup>CD11b<sup>−</sup>Gr1<sup>bright</sup>CD44<sup>bright</sup>) were isolated from lungs of male A/J mice using anti-CD11c-PerCP/Cy5.5 (HL3), anti-CD11b-PE-Cy7 (M1/70), anti-Gr-1-APC-Cy7 (RB6-8C5), anti-CD103-FTTC (2E7), and anti-CD317-AF647 (eBio129c). Co-stimulatory molecule expression was examined using phycocyaninythrin-conjugated mAbs to major histocompatibility complex class II (14-4-4s) and PD-L2 (TY25). mAbs were purchased from eBioscience (San Diego, CA). Antigen uptake was measured in the Pacific Blue channel following administration of AF405-conjugated HDM. Dead cells were excluded using Live/Dead Blue (Invitrogen). Data were acquired with an LSRII flow cytometer equipped with lasers tuned to 355 nm, 405 nm, 488 nm, 562 nm, and 640 nm, and digital DiVa Software (BD Biosciences, San Jose, CA). FlowJo software (Treestar, Ashland, OR) was used to compensate spectral overlap and analyze data.

Subject recruitment. Subjects with no asthma or well-defined mild and severe asthma were recruited from the Montreal Chest Institute and Sacré-Cœur Hospital (Montreal, Quebec, Canada) based on the criteria of the American Thoracic Society Thoracic workshop for Refractory Asthma.62 As described elsewhere,63 mild asthmatics had FEV1 <70% predicted or FEV1/FVC (forced expiratory volume in one second) readings ≥ 70% postbronchodilator and required infrequent use of inhaled short-acting β2-agonist medication alone. Severe asthmatics had at least one of (1) treatment with daily inhaled steroids for > 50% of the previous 12 months or (2) treatment with high-dose inhaled steroids and at least one other add-on therapy continuously over the past 12 months. In addition, two or more of the following were required: (1) daily use of short-acting β-agonist; (2) persistent airflow obstruction as documented by prebronchodilator FEV1 <70% predicted; (3) at least one urgent care visit in the previous 12 months; (4) ≥ 3 steroid bursts in the previous 12 months; (5) prompt deterioration with <25% dose reduction of steroids; or (6) a near-fatal asthma event in the past 3 years. Detailed definition of the inclusion and exclusion criteria for the enrollment of asthmatic subjects were reported previously.64 The protocols for the study were reviewed and approved by the ethics committees of both hospitals, and informed consent was obtained from all participating subjects. DNA was extracted from lung biopsies using the NEnasy columns, reverse transcribed with oligo(dT) (Amersham) and Superscript II (Invitrogen), in the presence of RNaseguard (Amersham, Piscataway, NJ).

Quantitative RT–PCR. PCR primer pairs for mPD-L2, mFIZZ1, mArg1, mSPRR2b, mCD206, mC3, mS14, mIL-5, mIL-13, and SAC were designed to span an intronic region to avoid co-amplification of genomic DNA. Gene expression in mouse cells was analyzed by RT–PCR using the iCycler system (Bio-Rad, Hercules, CA) and SYBR green, while gene expression in human bronchial biopsies was done by RT–PCR using the StepOnePlus PCR system (Applied Biosystems, San Francisco, CA) and SYBR green. Gene expression analysis was performed using the ΔΔCt method described elsewhere.65

Generation and stimulation of BMDCs. Bone marrow cells (3 × 10<sup>5</sup> cells ml<sup>−1</sup>) were cultured in complete RPMI 1640 supplemented with granulocyte macrophage colony-stimulating factor (10 ng ml<sup>−1</sup>; Peprotech, Rocky Hill, NJ). Medium was changed on day 3 and harvested on day 6. In all, 250,000 cells were plated on wells coated with 5 µg ml<sup>−1</sup> PD-L1-Fc, PD-L2-Fc, or control IgG-Fc (R&D Systems) and stimulated with 30 µg ml<sup>−1</sup> HDM or 100 ng ml<sup>−1</sup> LPS for 24 h. Culture supernatants were harvested to assay IL-12 p70, IL-6, TNF-α, IL-1β (Pharmingen, San Diego, CA), and IL-23 (R&D Systems, Minneapolis, MN) by enzyme-linked immunosorbent assay. Where indicated, BMDCs were stimulated with IL-12, IL-13, or IL-12 + IL-13 (all 10 ng ml<sup>−1</sup>) for 24 h. RNA was harvested for PCR analysis. Where indicated, cultures also included anti-CD-1 (clone RMP1-14; eBioscience) at 5 µg ml<sup>−1</sup>
Mouse tracheal epithelial cells isolation. Tracheas from 4–6-week-old mice were removed from the thyroid cartilage to the level of bifurcation and incubated in Pronase (1 mg ml⁻¹; Roche Applied Science, Indianapolis, IN) and incubated (18 h × 4 °C while rocking). The next day, 10% FBS and 1 mg ml⁻¹ DNase (Sigma-Aldrich, St Louis, MO) were added, and the tube inverted multiple times. The trachea was discarded; cells were washed and plated onto a cell culture plate with Primaria surface treatment (BD Biosciences, Bedford, MA) for 4 h to remove fibroblasts. Non-attached cells were washed, counted, and plated in DMEM/F12 (50/50 containing L-glutamine (2 mM), penicillin (100 U ml⁻¹)/streptomycin (100 µg ml⁻¹)), NaHCO₃ (3.6 mM), FBS (5%), Cholera toxin (0.1 µg ml⁻¹), mouse epithelial growth factor (0.5 ng ml⁻¹), amphotericin B (0.25 µg ml⁻¹), bovine pituitary extract (50 µg ml⁻¹), insulin-transferrin-selenium media supplement (Sigma Chemical, St Louis MO), and retinoic acid (0.1 ng ml⁻¹). mTECs were grown on collagen-coated 6-well tissue culture plates until confluent. mTECs were stimulated with nothing, IL-13 (10 ng ml⁻¹), or IL-12 + IL-13 (both at 10 ng ml⁻¹) for 24 h. Cells were lysed with Trizol, total RNA was isolated, and cDNA synthesized to measure gene expression by RT–PCR.

Western blot. For western blot analysis of STAT6 phosphorylation, BMDCs from BABL/c mice were generated as described above. After harvest, 2.5 million BMDCs were plated in complete RPMI culture medium (containing 10% fetal bovine serum (FBS)) in single wells of a 24-well plate and allowed to adhere for 12 h. After 12 h, the culture medium was removed, and BMDCs were starved in RPMI containing 0.1% FBS overnight. The following morning cells were stimulated with medium alone (containing 0.1% FBS), IL-12, IL-13, or IL-12 + IL-13 (all at 10 ng ml⁻¹) for 15 min. Cells were immediately placed on ice, washed with ice-cold PBS, and lysed with a lysis buffer containing protease inhibitors (Roche, Indianapolis, IN) and phosphatase inhibitor cocktails (CalBiochem, Gibbstown, NJ). Lysates were stored at −80 °C until required. Total proteins (10 µg) were separated by electrophoresis on an sodium dodecyl sulfate polyacrylamide gel and transferred onto PVDF membranes and blocked with 5% BSA for 1 h at room temperature. Afterwards, the membranes were incubated overnight with primary antibodies (in 5% BSA in TBS) as follows: rabbit anti-human/mouse phospho-STAT6 (Tyr761) (1:10,000, Cell Signaling Technology, Beverly, MA), rabbit anti-mouse STAT6 (1:10,000, Cell Signaling Technology), or anti-α-tubulin (1:10,000, Cell Signaling Technology). Membranes were washed and incubated for 1 h at room temperature with an HRP-conjugated goat anti-rabbit (3:1000; Cell Signaling Technology). Membranes were then washed and incubated for 1 h at room temperature with an HRP-conjugated goat anti-rabbit secondary (in 5% BSA in TBS at 1:10,000, Cell Signaling Technology). Blots were developed using an ECL Prime (GE Healthcare, Pittsburgh, PA).

Statistical analysis. To determine differences between multiple groups, analysis of variance was used with post hoc comparisons using Tukey’s method. For comparison between two groups, a Student’s t-test was performed. In human samples, analysis of variance was used comparing using the Kruskal–Wallis test. Significance was assumed at P < 0.05.
