ABSTRACT

We present the signal processing framework and some results for the IEEE AASP challenge on acoustic source localization and tracking (LOCATA). The system is designed for the direction of arrival (DOA) estimation in single-source scenarios. The proposed framework consists of four main building blocks: pre-processing, voice activity detection (VAD), localization, tracking. The signal pre-processing pipeline includes the short-time Fourier transform (STFT) of the multichannel input captured by the array and the cross power spectral density (CPSD) matrices estimation. The VAD is calculated with a trace-based threshold of the CPSD matrices. The localization is then computed using our recently proposed diagonal unloading (DU) beamforming, which has low-complexity and high resolution. The DOA estimation is finally smoothed with a Kalman filter (KF). Experimental results on the LOCATA development dataset are reported in terms of the root mean square error (RMSE) for a 7-microphone linear array, the 12-microphone pseudo-spherical array integrated in a prototype head for a humanoid robot, and the 32-microphone spherical array.

Index Terms— Acoustic source localization, speaker tracking, diagonal unloading beamforming, LOCATA, Kalman filter, microphone array.

1. INTRODUCTION

The aim of an acoustic source localization and tracking system is to estimate the position of sound sources in space by analyzing the sound field with a microphone array, a set of microphones arranged to capture the spatial information of sound. Speaker spatial localization/tracking using microphone arrays is of considerable interest in applications of teleconferencing systems, hands-free acquisition, human-machine interaction, recognition, and audio surveillance.

In this paper, we present the signal processing framework for the IEEE AASP challenge on acoustic source localization and tracking (LOCATA) [1]. We also present some performance results related to the LOCATA development dataset. The proposed localization and tracking system is designed for the direction of arrival (DOA) estimation in single-source scenarios. The localization algorithm is based on diagonal unloading (DU) beamforming, recently introduced in [2]. Broadband DU localization beamformer is computed in the frequency-domain [3] by calculating the steered response power (SRP) on each frequency bin and by summing the narrowband components with the incoherent frequency fusion [4]. The tracking is performed with a Kalman filter (KF) [5].

2. METHOD

The proposed system consists of four main building blocks:

- pre-processing;
- voice activity detection (VAD);
- localization;
- tracking.

The organization of the signal processing components is illustrated in Figure 1.

2.1. Pre-Processing

The signal pre-processing pipeline includes the short-time Fourier transform (STFT) of the multichannel input captured by the array $x_m(t)$ ($m = 1, 2, \ldots, M$, where $M$ is the number of microphones). It can be expressed as

$$X_m(k, f) = \sum_{l=-L}^{L} x_m(l + kR)e^{-j2\pi ft}, \quad k = 0, 1, \ldots,$$

(1)

where $k$ is the frame time index, $f$ is the frequency bin, $w(l)$ is the analysis window, $L$ is the size of the fast Fourier transform (FFT), and $R$ is the hop size.

After the frequency-domain transformation, the cross power spectral density (CPSD) matrices $\Phi(k, f)$ of the considered frequency range $[f_{\text{min}}, f_{\text{max}}]$ are estimated through the averaging of the array signal blocks [6]

$$\Phi(k, f) = \frac{1}{N} \sum_{k_n=0}^{N-1} x(k - k_n, f) x^H(k - k_n, f),$$

(2)

$$f = f_{\text{min}}, f_{\text{min}} + 1, \ldots, f_{\text{max}},$$

where $N$ is the number of frames for the averaging, $H$ denotes the conjugate transpose operator, and

$$x(k, f) = [X_1(k, f), X_2(k, f), \ldots, X_M(k, f)]^T,$$

(3)

where $T$ denotes the transpose operator.

2.2. VAD

The VAD used herein is based on the trace of the CPSD matrices that is related on the DU beamforming. The trace of a CPSD matrix is equivalent to the sum of the eigenvalues of the matrix, i.e., it

$$\text{trace} [\Phi(k, f)] = \sum_{l} \lambda_l,$$

where $\lambda_l$ are the eigenvalues of $\Phi(k, f)$. A threshold is then applied to each trace to identify the presence of acoustic sources. The threshold is calculated with a trace-based thresholding method [4].
represents the overall power of the array. The source detection is hence calculated as

\[
\text{VAD}(k) = \begin{cases} 
1, & \text{if } \sum_{f=f_{\text{min}}}^{f_{\text{max}}} \text{tr}[\hat{\Phi}(k,f)] > \eta, \\
0, & \text{otherwise},
\end{cases}
\]

where \(\text{tr}[\cdot]\) is the operator that computes the trace of a matrix, and \(\eta\) is a given threshold. The parameter \(\eta\) was empirically set to the value allowing to effectively detect the source activity.

### 2.3. Localization

The acoustic source DOA estimation method is a low complexity and robust beamformer based on a DU transformation of the covariance matrix involved in the conventional beamformer computation to exploit the high resolution subspace orthogonality property. The method is illustrated in details in [2].

The transformation, on which the DU method is based, is obtained by subtracting an opportune diagonal matrix from the CPSD matrix \(\hat{\Phi}(k, f)\) of the array output vector. As a result, the DU beamforming removes as much as possible the signal subspace from the covariance matrix and provides a high resolution beampattern. In practice, the design and implementation of the DU transformation is simple and effective, and is obtained by computing the matrix (un)loading factor.

The broadband SRP is defined as [2, 4]

\[
P(k, \Omega_d) = \sum_{f=f_{\text{min}}}^{f_{\text{max}}} P_{\text{DU}}(k, f, \Omega_d),
\]

where \(\Omega_d = [\theta_d, \phi_d] \) (\(\theta_d\) and \(\phi_d\) are the azimuth and elevation angles) is the steering direction, \(\|\cdot\|_\infty\) denotes the Uniform norm, i.e., the maximum value of the vector

\[
g(k, f) = [P_{\text{DU}}(k, f, \Omega_1), P_{\text{DU}}(k, f, \Omega_2), \ldots, P_{\text{DU}}(k, f, \Omega_D)],
\]

which contains all the narrowband SRP for the considered search direction \(D\), and the narrowband DU response power beamforming \(P_{\text{DU}}(k, f, \Omega_d)\) is defined as

\[
P_{\text{DU}}(k, f, \Omega_d) = \frac{1}{a^T(f, \Omega_d) [\text{tr}[\hat{\Phi}(k,f)] I - \hat{\Phi}(k,f)] a(f, \Omega_d)},
\]

where \(a(f, \Omega_d)\) is the array steering vector for the direction \(\Omega_d\), and \(I\) is the identity matrix. Note that the unloading parameter is computed with the trace operation of the PSD matrices. This solution guarantees that the transformed PSD matrix \(\hat{\Phi}_{\text{DU}}(k, f) = [\text{tr}[\hat{\Phi}(k,f)] I - \hat{\Phi}(k,f)]\) has the attenuation of the signal subspaces with respect to the noise subspace, and hence the high resolution orthogonality is exploiting, even if partially, since the transformed PSD matrix is affected by a certain amount of signal subspace [2].

The array steering vector depends on the array geometry. Note that for the linear array the steering direction is given only by the azimuth angle.

Then, the DOA estimate of the source is obtained by

\[
\hat{\Omega}_d(k) = \arg\max_{\Omega_d} [P(k, \Omega_d)], \quad d = 1, 2, \ldots, D.
\]

### 2.4. Tracking

The KF [5] is an optimal recursive Bayesian filter for linear systems observed in the presence of Gaussian noise. The filter equations can be divided into a prediction and a correction step. The state of the process is given by

\[
y(k) = [\Omega(k), v_{\theta}(k), v_{\phi}(k)]^T,
\]

where \(v_{\theta}(k)\) and \(v_{\phi}(k)\) are the velocities. In the prediction step the update equations are

\[
y_p(k) = Ay(k-1),
\]

\[
P_p(k) = AP(k-1)A^T + BQB^T,
\]

where

\[
A = \begin{bmatrix}
1 & 0 & dt & 0 \\
0 & 1 & 0 & dt \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix},
\]

\[
B = \begin{bmatrix}
0.5dt^2 & 0 \\
0 & 0.5dt^2 \\
dt & 0 \\
0 & dt
\end{bmatrix},
\]

\[
Q = \begin{bmatrix}
\sigma^2_{\theta} & 0 \\
0 & \sigma^2_{\phi}
\end{bmatrix},
\]

with \(\sigma^2_{\theta}\) being the variance of the process error, \(dt = RN/f_s\) the time elapsed between DOA estimations, \(f_s\) the sampling rate. The filter is initialized with the state covariance matrix \(P(k_0) = \text{BQB}^T\) and the state \(y(k_1) = [\hat{\Omega}_d(k_1), 0, 0]^T\), where \(k_1\) is the first time frame in which the VAD\((k_i)\) has value 1 and VAD\((k_i-1)\)=0. After the prediction step, the Kalman gain is calculated as

\[
K = P_p(k)C^T(CP_p(k)C^T + R)^{-1},
\]
where
\[
C = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0
\end{bmatrix},
\]
(16)
\[
R = \begin{bmatrix}
\sigma_r^2 & 0 \\
0 & \sigma^2
\end{bmatrix},
\]
(17)
with \( \sigma^2 \) being the variance of the measurement error. In the correction step the measurement update equations are
\[
y(k) = y_p(k) + K(\hat{\Omega}_r(k) - Cy_p(k)),
\]
(18)
\[
P(k) = (I - KC)P_p(k).
\]
(19)
Hence, after the correction step the filtered DOA estimation \( \hat{\Omega}^{\text{KF}}_r(k) = \Omega(k) \) is obtained.

3. EXPERIMENTAL RESULTS

We present some experimental results on the LOCATA development dataset to show the performance of the proposed framework in the single-source scenario with:

- static loudspeaker and static array (task 1);
- moving speaker and static array (task 3);
- moving speaker and moving array (task 5).

We tested the system with the distant talking interfaces for control of interactive TV (DICIT) array by considering a 7-microphone linear subarray ([4 5 6 7 9 10 11]) taking into account the far-field of interactive TV (DICIT) array by considering a 7-microphone linear array, the robot head pseudo-spherical array, and the 32-microphone eigenmike spherical array. The system setup is implemented with a humanoid robot array, and the 32-microphone ear subarray ([4 5 6 7 9 10 11]) taking into account the far-field of interactive TV (DICIT) array.

We showed some results with the LOCATA development dataset to show the performance of the proposed framework in the single-source scenario. We described the four main building blocks (pre-processing, VAD, localization and tracking) for the DOA estimation of a single source. We described the four main building blocks (pre-processing, VAD, localization and tracking) for the DOA estimation of a single source. We showed some results with the LOCATA development dataset using a linear array, the robot head pseudo-spherical array, and the eigenmike spherical array.

4. CONCLUSIONS

The signal processing framework based on a DU beamforming and a KF for the IEEE AASP LOCATA challenge has been presented. We described the four main building blocks (pre-processing, VAD, localization, tracking) for the DOA estimation of a single source. The signal processing framework has been implemented using Matlab R2017a. We used our own implementation for the KF. The performance was assessed in terms of the root mean square error (RMSE). Table 1 shows the DOA estimation results for each task and each recording. The azimuth angle was evaluated for the linear array and each recording, while both azimuth and elevation angles was considered for the robot head and eigenmike array. Three examples of detection, localization and tracking are depicted in Figures 2, 3, 4. Figure 2 shows the performance of the linear array for the task 1 (static loudspeaker, static array) and recording 3. Figure 3 shows the performance of the robot head array for the task 3 (moving speaker, static array) and recording 3. Figure 4 shows the performance of the eigenmike array for the task 5 (moving speaker, moving array) and recording 1. The top plot shows the waveform of channel 1 with the speaker activity (red line).
