(Communicated by Alain Miranville)

Abstract. We consider an evolution system describing the phenomenon of marble sulphation of a monument, accounting of the surface rugosity. We first prove a local in time well posedness result. Then, stronger assumptions on the data allow us to establish the existence of a global in time solution. Finally, we perform some numerical simulations that illustrate the main feature of the proposed model.

1. Introduction. Deterioration and damage of stones is a complex problem and one of the main concern for people working in the field of conservation and restoration of cultural heritage. It is extremely difficult to isolate a single factor in this kind of processes, which are the results of the interaction of various mechanisms. These processes can be described through free boundary models, as in the case of damage induced by pollution, or by using a phase field approach. We introduce a new differential system coupling bulk and surface evolution equations to describe the phenomenon of marble sulphation of a monument, including the surface rugosity.

More precisely, we consider a monument made of calcium carbonate stone, located in a bounded domain \( \Omega \subset \mathbb{R}^3 \), with a smooth boundary \( \Gamma \), and subjected to a degradation process during a time interval \( (0, T) \), for any given \( T > 0 \).
Following the approach introduced in \cite{1, 5, 8, 9, 10, 11} for related models of marble sulphation, we consider the system
\begin{align}
(\phi(c)s)_t - \text{div} (\phi(c)\nabla s) &= -\lambda \phi(c)sc, \quad \text{in } \Omega \times (0, T), \quad (1.1) \\
c_t &= -\lambda \phi(c)sc, \quad \text{in } \Omega \times (0, T), \quad (1.2) \\
\phi(c)c_t s &= -\nu(r)(s - \bar{s}), \quad \text{on } \Gamma \times (0, T), \quad (1.3) \\
r_t + \partial W(r) + \Psi'(r) + G(r, c, s) \ni F, \quad \text{on } \Gamma \times (0, T), \quad (1.4)
\end{align}
equipped with the set of initial conditions
\begin{equation}
s(0) = s_0, \quad \text{in } \Omega, \quad c(0) = c_0 \quad \text{in } \Omega, \quad r(0) = r_0 \quad \text{on } \Gamma. \quad (1.5)
\end{equation}
Here $s$ stands for the $SO_2$ porous concentration inside the material, $c$ represents the local density of $CaCO_3$ and $r \geq 0$ denotes the rugosity of the surface. We indicate by $n$ the outward normal derivative to $\Gamma$.

The first equation describes the evolution of the porous concentration of $SO_2$, where $\phi(c)$ is the porosity of the medium. This evolution is driven by the Fick’s law and on the right hand side we have the reaction term between $SO_2$ and calcium carbonate, with rate $\lambda > 0$. The second equation takes into account for the loss of calcium carbonate due the reaction.

The novelty in this model with respect to \cite{1, 8} is the introduction of the Robin boundary condition (1.3) for the flux of $SO_2$ through the external boundary, depending not only on the porosity of the medium and the external concentration $\bar{s}$, but also on an effective permeability coefficient $\nu$, which is a function of the superficial rugosity $r$.

Let us now describe what $r$ represents. From the physical point of view the rugosity is quite a complex quantity, corresponding locally to the microscopic variation of a surface with respect to a flat configuration. For a precise definition see, for instance, \cite{16, 17}. Actually, in our model $r$ stands for an effective macroscopic parameter which is formally a local damage parameter. As $r$ grows, the profile of the surface has a greater deviation from the flat configuration and the microscopic density of peaks and valleys increases. In practice, this corresponds to a greater surface exposed to the pollution action, implying an increasing of the $SO_2$ flux permeability coefficient. Here, the value $r = 0$ corresponds to a completely smooth surface. Moreover, we deal with a material in which the “direction” of the evolution of $r$ is not a priori fixed, i.e. $r$ may increase or decrease through different external actions or repairing itself. The evolution of $r$ is governed by the damage-like equation (1.4) (cf., e.g., \cite{4, 7, 13} and the references therein). The symbol $\partial W$ stands for the subdifferential of a proper, convex, and lower semicontinuous function $W$, accounting for possible internal constraints on $r$. The function $G$ depends in particular on $c$ and $s$ through the porosity function $\phi(c)$ and satisfies $G(r, 0, s) = G(r, c, 0) = 0$. The function $\Psi'$ is sufficiently smooth and accounts for the non-monotone dynamics of $r$. The function $F$ on the right hand side of (1.4) denotes possible external actions responsible for the formation of rugosity on the boundary, like, e.g., wind, rain or temperature variations.

It is worth noting that, as many dissipative evolution equations, our system (1.1)-(1.4) has a gradient flow structure (see, e.g., \cite{12}). Indeed, let us introduce the energy functionals
\begin{equation}
\mathcal{E}_1[c, s, r] = \int_{\Omega} \left( \frac{\phi(c)}{2} |\nabla s|^2 + \lambda c \phi(c) \frac{s^2}{2} - \lambda \phi'(c) \phi(c)c \frac{s^3}{3} \right) + \int_{\Gamma} \frac{\nu(r)}{2} |s - \bar{s}|^2, \quad (1.6)
\end{equation}
\[ \mathcal{E}_2[c, s, r] = \int_\Gamma (W(r) + \Psi(r) + \tilde{G}(r, c, s) - Fr), \]

where \( \tilde{G} \) is such that \( G = \partial_r \tilde{G} \). Then, using the kinetic equation (1.2) and letting

\[
\mathcal{R}_1[s_t] = \frac{1}{2} \int_\Omega \phi(c)|s_t|^2, \quad (1.7)
\]

\[
\mathcal{R}_2[r_t] = \frac{1}{2} \int_\Gamma |r_t|^2, \quad (1.8)
\]

we can formally write (1.1), combined with (1.3) and (1.4), as

\[
\partial \mathcal{R}_1 + \partial_c \mathcal{E}_1 = 0, \quad (1.9)
\]

\[
\partial \mathcal{R}_2 + \partial_c \mathcal{E}_2 \geq 0. \quad (1.10)
\]

Actually here we do not exploit this structure since we use only standard energy arguments, but this remark could be helpful for future developments.

In this paper we first prove a local in time well posedness result for system (1.1)–(1.5) in finite energy spaces. Next, under slightly stronger assumptions, we can establish some uniform bounds for the solution which in turn imply the global in time existence. Finally, we perform some numerical finite element simulations to assess the behavior of our model according to different physical situations.

The plan of the paper is the following. Section 2 is devoted to the statement of the main theorems and assumptions. The proof of the local existence result is detailed in Section 3. Section 4 contains the proof of the global existence result. Finally, in Section 5 we present the numerical simulations.

2. Main results. In this section, we introduce the formulation of system (1.1)–(1.5) in the correct functional setting and we state the main results. From now on, for the sake of simplicity, we will take \( \lambda = 1 \).

First of all, we assume that the porosity function \( \phi \) is a linear function of the density \( c \), i.e.,

\[
\phi(c) = A + Bc, \quad (2.1)
\]

where \( A \) and \( B \) are constants (see [9] and the references therein).

Concerning the data, throughout the paper we make use of the following assumptions

\[
W : [0, +\infty) \rightarrow [0, +\infty] \text{ is convex and l.s.c., } W(0) = 0, \quad (2.2)
\]

\[
\Psi \in W^{2,\infty}(\mathbb{R}), \quad G \in W^{1,\infty}(\mathbb{R}^3), \quad F \in L^2(0, T; L^2(\Gamma)), \quad (2.3)
\]

\[
s \in H^{1/2}(\Gamma), \quad s \geq 0, \text{ a.e. in } \Gamma, \quad (2.4)
\]

\[
\nu \in W^{1,\infty}(\mathbb{R}), \quad \nu \geq 0, \text{ a.e. in } \mathbb{R}, \quad (2.5)
\]

\[
c_0 \in H^2(\Omega), \quad 0 \leq c_0(x) \leq C_0, \quad \forall x \in \Omega, \quad (2.6)
\]

\[
s_0 \in H^2(\Omega), \quad s_0(x) \geq 0, \quad \forall x \in \Omega, \quad (2.7)
\]

\[
r_0 \in L^2(\Gamma), \quad W(r_0) \in L^1(\Gamma), \quad r_0 \geq 0, \text{ a.e. in } \Gamma, \quad (2.8)
\]

\[
\phi(c_0) \partial_s s_0 = -\nu(r_0)(s_0 - s), \text{ a.e. in } \Gamma, \quad (2.9)
\]

\[
A > 0, \quad A + BC_0 > 0, \quad (2.10)
\]

\[
0 \leq s \leq S_0, \text{ a.e. in } \Gamma, \quad 0 \leq s_0(x) \leq S_0, \quad \forall x \in \Omega, \quad B \leq \frac{1}{S_0}. \quad (2.11)
\]
**Remark 2.1.** We are considering the case in which \( \bar{s} \) does not depend on \( t \), i.e. \( \bar{s}_t = 0 \), for the sake of simplicity. Note in addition that, by Sobolev’s embeddings, \( \bar{s} \in L^4(\Gamma) \).

**Remark 2.2.** We recall that if \( W \) is convex and lower semicontinuous then the subdifferential \( \partial W \) is a maximal monotone operator defined as
\[
\partial W(\sigma_0) = \{ \xi \in \mathbb{R} : W(\sigma) \geq W(\sigma_0) + \xi(\sigma - \sigma_0) \}.
\]

**Remark 2.3.** It is reasonable to impose a constraint on \( r \) so that \( r \in [0, R_0] \), where \( R_0 > 0 \) depends on the crystals dimension for the material we are considering. Actually, we can ensure the validity of this internal constraint assuming in (2.2), e.g.,
\[
W(x) = I_{[0,R_0]}(x) = \begin{cases} 0, & \text{if } x \in [0,R_0], \\ +\infty, & \text{elsewhere}. \end{cases}
\]

We can now formulate our problem

**Problem (P).** Find a triplet \((s, c, r)\) such that
\[
\begin{align*}
s & \in H^1(0, T; L^2(\Omega)) \cap L^\infty(0, T; H^1(\Omega)) \cap L^2(0, T; H^2(\Omega)), \\
c & \in H^1(0, T; H^2(\Omega)), \\
r & \in H^1(0, T; L^2(\Gamma)), \\
s & \geq 0, \quad 0 \leq c \leq C_0, \quad \text{a.e. in } \Omega \times (0, T),
\end{align*}
\]
and satisfying
\[
\begin{align*}
(\phi(c)s)_t - \text{div} (\phi(c)\nabla s) & = -\phi(c)sc, \quad \text{a.e. in } \Omega \times (0, T), \\
\phi(c)\partial_n s & = -\nu(r)(s - \bar{s}), \quad \text{a.e. on } \Gamma \times (0, T), \\
c_t & = -\phi(c)cs, \quad \text{a.e. in } \Omega \times (0, T), \\
r_t + \xi + \Psi'(r) + G(r, c, s) & = F, \quad \xi \in \partial W(r), \quad \text{a.e. on } \Gamma \times (0, T), \\
s(0) & = s_0, \quad c(0) = c_0, \quad \text{a.e. in } \Omega, \quad r(0) = r_0, \quad \text{a.e. on } \Gamma.
\end{align*}
\]

We can now state our main existence results. The first theorem concerns the existence of a local in time solution.

**Theorem 2.4.** Let \( T > 0 \) and (2.2)–(2.9) hold. Then there exists a time \( \hat{T} \in (0, T] \) such that Problem (P) admits a unique solution in \((0, \hat{T})\). Moreover, the following properties hold
\[
\begin{align*}
s & \in W^{1,\infty}(0, \hat{T}; L^2(\Omega)) \cap H^1(0, \hat{T}; H^1(\Omega)) \cap L^\infty(0, \hat{T}; H^2(\Omega)), \\
c & \in W^{1,\infty}(0, \hat{T}; H^2(\Omega)) \cap W^{2,\infty}(0, \hat{T}; L^2(\Omega)), \\
s & \geq 0, \quad 0 \leq c \leq C_0, \quad \text{a.e. in } \Omega \times (0, \hat{T}), \\
\xi & \in L^2(0, \hat{T}; L^2(\Gamma)).
\end{align*}
\]

Assumption (2.10) allows us to extend the existence of the solution to the whole time interval \((0, T)\).

**Theorem 2.5.** Let \( T > 0 \) and (2.2)–(2.10) hold. Then there exists a unique global solution to Problem (P) on the whole time interval \((0, T)\). Moreover, the following properties hold
\[
\begin{align*}
s & \in W^{1,\infty}(0, T; L^2(\Omega)) \cap H^1(0, T; H^1(\Omega)) \cap L^\infty(0, T; H^2(\Omega)), \\
\end{align*}
\]
Consequently, by (3.3), we can define an operator $R$

\begin{align}
\text{Proof of Theorem 2.4.} \\
3. (2.26)), our results also hold if $G$ locally Lipschitz with respect to $c$ and $s$ (see (2.2)).
\end{align}

Let us point out that, due to the uniform bound on $c$ and $s$ (see (2.26)), our results also hold if $G$ locally Lipschitz with respect to $c$ and $s$ (see (2.2)).

3. **Proof of Theorem 2.4.** We consider problem (2.15)–(2.19). Let us define, for $R > \|s_0\|_{L^2(\Omega)}$ and $T > 0$, the subset

$$\mathcal{X}_{R,T} := \{ s \in C([0, T]; L^2(\Omega)) \cap L^2(0, T; H^2(\Omega)) : \|s\|_{L^2(0, T; L^2(\Omega)) \cap L^2(0, T; H^2(\Omega))} \leq R, \quad s \geq 0, \quad \text{a.e. in } \Omega \times (0, T) \},$$

where $T$ will be fixed later on as a function of $R$. We aim to construct a mapping

$$S : \mathcal{X}_{R,T} \to \mathcal{X}_{R,T}$$

which results to be a contraction for a suitable choice of $T$, with respect to the norm of $C([0, T]; L^2(\Omega)) \cap L^2(0, T; H^2(\Omega))$. As a consequence, we will deduce that it admits a unique fixed point and we will show that this fixed point provides a solution to Problem (P).

By abusing of notation, in the following we will use the same symbol $C$ for possibly different positive constants, depending only on the data of the problem, on $\Omega$ and (continuously) on $T$ at most; while $C(R)$ will denote a positive constant which also depends on $R$.

3.1. **First step: finding $c$.** Let us fix $\hat{s} \in \mathcal{X}_{R,T}$ and consider the following problem (cf. (1.2), (1.5) and (2.1))

$$c_0 = -Ac\hat{s} - Bc^2\hat{s}, \quad c(0) = c_0 \quad \text{a.e. in } \Omega. \quad (3.2)$$

This is actually a Cauchy problem (in time) for a Bernoulli type equation for $c$, which has the explicit solution

$$\hat{c}(x, t) = \frac{Ac_0(x)}{(A + Bc_0(x))e^{\int_0^t \hat{c}(x, \tau)d\tau} - Bc_0(x)}, \quad \text{in } \Omega \times (0, T). \quad (3.3)$$

Consequently, by (3.3), we can define an operator $\mathcal{S}_t(\hat{s}) = \hat{c}$. Then, exploiting the bounds on $c_0$ (see (2.5)) and on $A$ and $B$ (see (2.9)), we deduce

$$A + Bc_0(x) \geq \begin{cases} A > 0, & \text{if } B \geq 0, \\ A + BC_0 > 0, & \text{if } B < 0, \end{cases} \quad \forall x \in \Omega. \quad (3.4)$$

So that, we have

$$(A + Bc_0(x))e^{\int_0^t \hat{c}(x, \tau)d\tau} - Bc_0(x) > A + Bc_0(x) - Bc_0(x) > A > 0, \quad \text{in } \Omega \times (0, T),$$

and then (cf. also (3.3))

$$0 \leq \hat{c}(x, t) \leq c_0(x) \leq C_0, \quad \text{in } \Omega \times (0, T), \quad (3.5)$$

$$\hat{c}(x, t) \leq 0, \quad \text{a.e. in } \Omega \times (0, T). \quad (3.6)$$

As a consequence we deduce, for all $(x, t) \in \Omega \times (0, T)$, the following inequalities

$$0 < A + \hat{c}(x, t) \leq A + BC_0, \quad \text{if } B \geq 0, \quad (3.7)$$

$$0 < A + BC_0 \leq A + \hat{c}(x, t) \leq A, \quad \text{if } B < 0. \quad (3.7)$$
Thus, using the Gronwall lemma and recalling (3.9), we eventually get

$$0 < m \leq A + B\hat{c}(x,t) = \phi(\hat{c}) \leq M, \text{ in } \Omega \times (0,T).$$ (3.8)

Moreover, (3.3) and the definition of $\mathcal{X}_{R,T}$ imply

$$\|\hat{c}\|_{L^2(0,T;H^2(\Omega))} \leq C(R).$$ (3.9)

By (3.2) we also get (see (2.1))

$$\|\hat{c}\|_{L^2(0,T;H^2(\Omega))} = \int_0^t \|\phi(\hat{c})\|_{H^2(\Omega)}^2 dt \leq C(R).$$ (3.10)

Thus, we eventually obtain

$$\|\hat{c}\|_{H^1(0,T;H^2(\Omega))} \leq C(R).$$ (3.11)

3.2. Second step: finding $r$. We indicate by $\hat{s}_R$, the trace on $\Gamma$ of the fixed $\hat{s} \in \mathcal{X}_R$. Analogously, $\hat{c}_R$ indicates the trace of $\hat{c}$ (given by (3.3)) on $\Gamma$. By construction of $\mathcal{X}_T$ and (3.11), we have that $\hat{s}_R, \hat{c}_R \in L^2(0,T;H^{3/2}(\Gamma))$. Here, for the sake of simplicity, we use the same notation $\hat{c}$ and $\hat{s}$ on $\Gamma$ also for their traces. Owing to standard theory for ordinary differential equations, exploiting (2.2) it is straightforward to find a unique $\hat{r} = S_2(\hat{s},\hat{c})$ solving the Cauchy problem, for almost any $x \in \Gamma$,

$$r_t + \xi + \Psi^t(r) + G(r,\hat{c},\hat{s}) = F, \text{ a.e. in } (0,T), \quad r(0) = \tau_0. \quad (3.12)$$

Testing (3.12) (replacing $r$ with $\hat{r}$) by $\hat{r}_t$ and integrating over $(0,t)$, by means of Young’s inequality, the smoothness conditions on $\Psi$ (see (2.2)) and the chain rule for the sub-differential $\partial W$, we obtain (see (2.7))

$$\frac{1}{2} \int_0^t \|\hat{r}_t\|_{L^2(\Gamma)}^2 + \int_\Gamma W(\hat{r}(t)) \leq \int_\Gamma W(\hat{r}(0)) + C \left(1 + \int_0^t \|\hat{s}\|_{L^2(\Gamma)}^2 + \|\hat{c}\|_{L^2(\Gamma)}^2\right) + \int_0^t \|F\|_{L^2(0,T;L^2(\Gamma))} + \int_0^t \|\hat{r}_t\|_{L^2(0,s;L^2(\Gamma))}$$

$$\leq C \left(1 + \int_0^t \|\hat{s}\|_{H^2(\Omega)}^2 + \|\hat{c}\|_{H^2(\Omega)}^2\right) + \int_0^t \|\hat{c}\|_{H^2(0,s;L^2(\Gamma))}.$$ (3.13)

Thus, using the Gronwall lemma and recalling (3.9), we eventually get

$$\|\hat{r}\|_{H^1(0,T;L^2(\Gamma))} \leq C(R).$$ (3.14)

3.3. Third step: finding $s$. We now consider the initial and boundary value problem (2.15), (2.16), (2.19), where $c = S_1(\hat{s})$ and $r = S_2(\hat{s},\hat{s}_1(\hat{s}))$. Applying standard results for linear parabolic equations, we have that there exists a unique solution $s = S_3(\hat{r},\hat{c}) = S(\hat{s})$ belonging to $H^1(0,T;H^1(\Omega)) \cap L^2(0,T;H^2(\Omega))$.

Testing the resulting equation by $s$ and integrating over $(0,t)$, we get

$$\int_0^t \int_\Omega (\phi(\hat{c})s)_t s + \int_0^t \int_\Omega \phi(\hat{c})|\nabla s|^2 + \int_0^t \int_\Gamma \nu(\hat{r})(s-\hat{s}) s + \int_0^t \int_\Omega \phi(\hat{c})\hat{c}s^2 = 0. \quad (3.15)$$

We first deal with the first integral on the left hand side, integrating by parts in time and exploiting (2.1) and (3.2). So that we obtain

$$\int_0^t \int_\Omega (\phi(\hat{c})s)_t s = \int_\Omega (\phi(\hat{c}(t))s^2(t) - \int_\Omega \phi(c_0)s_0^2 - \int_0^t \int_\Omega \phi(\hat{c})ss_t \quad (3.16)$$
Combining (3.15) with (3.16), we get (see (3.8) and (3.11))

\[ \hat{\hat{c}}(t) = \hat{\hat{c}}(0) + \int_0^t \frac{1}{2} \int_\Omega \phi(c_0) s_0^2 + \frac{1}{2} \int_\Omega s_0^2 \quad \text{and} \quad \int_0^t \int_\Gamma B \hat{c}_t s^2. \]

From which we deduce

\[ \hat{\hat{c}}(t) = \hat{\hat{c}}(0) + \int_0^t \frac{1}{2} \int_\Omega \phi(c_0) s_0^2 + \frac{1}{2} \int_\Omega s_0^2 \quad \text{and} \quad \int_0^t \int_\Gamma B \hat{c}_t s^2. \]

Let us consider the identities

\[ \int_0^t \int_\Omega \phi(\hat{c}(t)) s_t^2 = \frac{1}{2} \int_\Omega \phi(\hat{c}(t)) \left| \nabla s(t) \right|^2 - \frac{1}{2} \int_\Omega \phi(c_0) \left| \nabla s_0 \right|^2 \]

\[ - \frac{1}{2} \int_0^t \int_\Omega B \hat{c}_t \left| \nabla s \right|^2, \]

and

\[ \int_0^t \int_\Gamma \nu(\hat{r})(s - \bar{s}) s_t = \frac{1}{2} \int_\Gamma \nu(\hat{r}(t)) (s - \bar{s})^2(t) - \frac{1}{2} \int_\Gamma \nu(r_0) (s_0 - \bar{s})^2. \]
Observe now that

\[- \int_0^t \int_\Gamma \nu' (\hat{r}) \hat{r}_t (s - \bar{s})^2.\]

Then, on account of (3.23) and (3.24), from (3.22) we deduce

\[
\int_0^t \int_\Omega \left( \frac{1}{2} \int_\Omega \phi (\hat{c}) |s_t|^2 + \frac{1}{2} \int_\Omega \phi (\hat{c}(t)) |\nabla s(t)|^2 + \frac{1}{2} \int_\Gamma \nu (\hat{r}(t)) s^2(t) \right) \\
= \frac{1}{2} \int_0^t \int_\Omega B \hat{c}_t |\nabla s|^2 - \int_0^t \int_\Omega \phi'(\hat{c}) \hat{c}_t s_t - \int_0^t \int_\Omega \phi(\hat{c}) \hat{c}s_t \\
+ \frac{1}{2} \int_0^t \int_\Omega \phi(c_0)|\nabla s_0|^2 + \frac{1}{2} \int_\Gamma \nu(r_0)(s_0 - \bar{s})^2 + \frac{1}{2} \int_0^t \int_\Gamma \nu'(\hat{r}) \hat{r}_t (s - \bar{s})^2 \\
+ \int_0^t \nu(\hat{r}(t))s(t)\bar{s} - \int_0^t \int_\Gamma \nu(\hat{r}(t))\bar{s}^2.\]

Observe now that

\[
\left| \int_0^t \int_\Omega \phi'(\hat{c}) \hat{c}_t s_t \right| \leq |B| \int_0^t \int_\Omega \|\hat{c}_t\|_{L^\infty(\Omega)} \|s\|_{L^2(\Omega)} \|s_t\|_{L^2(\Omega)} \leq C(R). \tag{3.26}
\]

Recalling (3.14) and (3.21) we get

\[
\left| \int_0^t \int_\Gamma \nu'(\hat{r}) \hat{r}_t (s - \bar{s})^2 \right| \leq C \int_0^t \|\hat{r}_t\|_{L^2(\Gamma)} \|s - \bar{s}\|_{L^2(\Gamma)}^2 \leq C(R). \tag{3.28}
\]

Thus we deduce (see (3.20))

\[
\int_0^t \int_\Omega \phi(\hat{c}) \hat{c}s_t \leq M \int_0^t \|s\|_{L^2(\Omega)} \|s_t\|_{L^2(\Omega)} \leq \frac{m}{4} \int_0^t \|s_t\|_{L^2(\Omega)}^2 + \frac{M^2 C_0^2}{m} \int_0^t \|s\|_{L^2(\Omega)}^2 \leq \frac{m}{4} \int_0^t \|s_t\|_{L^2(\Omega)}^2 + C(R). \tag{3.30}
\]

Then, combining (3.26)–(3.30) with (3.25), we find

\[
\frac{m}{4} \|s_t\|_{L^2(0,T;L^2(\Omega))}^2 + \frac{m}{2} \|\nabla s\|_{L^\infty(0,T;L^2(\Omega))}^2 \leq C + C(R), \tag{3.31}
\]

which gives (see also (3.20))

\[
\|s_t\|_{L^2(0,T;L^2(\Omega))} + \|s\|_{L^\infty(0,T;H^1(\Omega))} \leq C(R). \tag{3.32}
\]
Actually, we can now estimate $s_t$ in $L^\infty(0, T; L^2(\Omega))$. To this aim let us (formally) differentiate the equation for $s$ with respect to time and get

$$
\phi(\hat{c})s_{tt} + 2B\hat{c}_t s_t + B\hat{c}_{tt}s - \text{div} (\phi(\hat{c})\nabla s)_t = -B\hat{c}_t \hat{c}_s - \phi(\hat{c})\hat{c}_t s_t.
$$

(3.33)

Observe that we can determine $s_1 = s_t(0)$ from the identity (cf. (1.1))

$$
- B\phi(c_0)s_0^2 c_0 + \phi(c_0)s_1 - \text{div}(\phi(c_0)\nabla s_0) = \phi(c_0)s_0 c_0,
$$

(3.34)

and, due to the regularity of $s_0$ and $c_0$, we can deduce that $s_1 \in L^2(\Omega)$. The boundary condition turns out to be rewritten as (see Remark 2.2)

$$
(\phi(\hat{c})\hat{c}_n)_t = \phi(\hat{c})\hat{c}_n s_t + B\hat{c}_t \hat{c}_n s = -\nu'(\tilde{r})\tilde{r}_t(s - \tilde{s}) - \nu(\tilde{r})s_t.
$$

(3.35)

In order to make our argument rigorous, we can observe, for instance, that the resulting problem (3.33)–(3.35) (written with respect to the unknown $\tilde{s} = s_t$) has the same structure of our original problem, and thus it admits a unique solution in the standard energy space.

We thus test (3.33) by $s_t$ and integrate over $(0, t)$, obtaining

$$
\frac{1}{2} \int_\Omega \phi(\hat{c}) s_t^2(t) - \frac{1}{2} \int_\Omega \phi(c_0)s_0^2 - \frac{1}{2} \int_0^t \int_\Omega B\hat{c}_t s_t^2 + 2B \int_0^t \int_\Omega \hat{c}_t s_t^2 \\
+ B \int_0^t \int_\Omega \hat{c}_t s_t - \int_0^t \int_\Gamma (\phi(\hat{c})\hat{c}_n s)_t s_t + \int_0^t \int_\Omega (\phi(\hat{c})\nabla s)_t \cdot \nabla s_t \\
= -B \int_0^t \int_\Omega \hat{c}_t \hat{c}_s s_t - \int_0^t \int_\Omega \phi(\hat{c})\hat{c}_t s_t - \int_0^t \int_\Omega \phi(\hat{c})\hat{c}_s^2,
$$

(3.36)

from which, recalling (3.2), (3.8) and (3.35), we deduce the identity

$$
\frac{1}{2} \int_\Omega \phi(\hat{c}) s_t(t)^2 - \frac{3}{2} \int_0^t \int_\Omega B\hat{c}_t s_t^2 - B \int_0^t \int_\Omega (\phi(\hat{c})s\hat{c})_t s s_t + \int_0^t \int_\Gamma \nu(\tilde{r}) s_t^2 \\
+ \int_0^t \int_\Gamma \nu'(\tilde{r})\tilde{r}_t(s - \tilde{s}) + \int_0^t \int_\Omega \phi(\hat{c})|\nabla s_t|^2 + \int_0^t \int_\Omega B\hat{c}_t \nabla s \cdot \nabla s_t \\
= \frac{1}{2} \int_\Omega \phi(c_0)s_0^2 - B \int_0^t \int_\Omega \hat{c}_t \hat{c}_s s_t - \int_0^t \int_\Omega \phi(\hat{c})\hat{c}_t s_t - \int_0^t \int_\Omega \phi(\hat{c})\hat{c}_s^2.
$$

(3.37)

Recalling the properties of $\hat{c}$, $\tilde{r}$ and $s$, from (3.37) we obtain the estimate

$$
\frac{1}{2} \int_\Omega \phi(\hat{c}(t))|s_t(t)|^2 + \int_0^t \int_\Omega \phi(\hat{c})|\nabla s_t|^2 + \int_0^t \int_\Gamma \nu(\tilde{r})|s_t|^2
\leq \frac{1}{2} \int_\Omega \phi(c_0)s_0^2 + |B| \int_0^t \int_\Omega |\hat{c}_t| L^\infty(\Omega)|\nabla s| L^2(\Omega)\|\nabla s_t\| L^2(\Omega)
\leq \frac{1}{2} \int_\Omega \phi(c_0)s_0^2 + |B| \int_0^t \int_\Omega |\hat{c}_t| L^\infty(\Omega)|\nabla s| L^2(\Omega)\|\nabla s_t\| L^2(\Omega)
\leq \frac{1}{2} \int_\Omega \phi(c_0)s_0^2 + |B| \int_0^t \int_\Omega |\hat{c}_t| L^\infty(\Omega)|\nabla s| L^2(\Omega)\|\nabla s_t\| L^2(\Omega)
+ M \int_0^t \int_\Omega |\hat{c}_t| L^\infty(\Omega)|\nabla s| L^2(\Omega)\|s_t\| L^2(\Omega) + MC_0 \int_0^t \int_\Omega |s_t| L^2(\Omega) + B \int_0^t \int_\Omega (\phi(\hat{c})s\hat{c})_t s s_t.
$$

(3.38)
On account of the Young inequality and the Sobolev injection $H^1(\Omega) \hookrightarrow L^4(\Omega)$, observe that it holds

$$
B \int_0^t \int_\Omega (\phi(\bar{c}) \tilde{s}_t) s_t s_t = B \int_0^t \int_\Omega (B \tilde{\sigma} \tilde{s}_t^2 s_t + \phi(\bar{c}) \tilde{s}_t^2 s_t + \phi(\bar{c}) \tilde{\sigma}_t^2 s_t)
$$

(3.39)

$$
\leq C \int_0^t \left( \|\tilde{\sigma}_t\|_{L^\infty(\Omega)} \|s\|^2_{L^4(\Omega)} \|s_t\|_{L^2(\Omega)} + \|s\|_{L^4(\Omega)} \|s_t\|_{L^2(\Omega)} \|s_t\|_{L^2(\Omega)} \right)
$$

$$
\leq C \int_0^t \left( \|\tilde{\sigma}_t\|_{L^\infty(\Omega)} \|s\|^2_{L^4(\Omega)} \|s_t\|_{L^2(\Omega)} + \|s\|_{L^4(\Omega)} \|s_t\|_{H^1(\Omega)} \|s_t\|_{L^2(\Omega)} \right)
$$

$$
\leq C \int_0^t \left( \|\tilde{\sigma}_t\|_{L^\infty(\Omega)} \|s\|^2_{L^4(\Omega)} \|s_t\|_{L^2(\Omega)} + \|s\|_{L^4(\Omega)} \|s_t\|_{L^2(\Omega)} \right)
$$

$$
+ C \int_0^t \|s\|_{L^4(\Omega)} \|\nabla s_t\|_{L^2(\Omega)} \|s_t\|_{L^2(\Omega)}
$$

$$
\leq C \int_0^t \left( \|\tilde{\sigma}_t\|_{L^\infty(\Omega)} \|s\|^2_{L^4(\Omega)} \|s_t\|_{L^2(\Omega)} + \|s\|_{L^4(\Omega)} \|s_t\|_{L^2(\Omega)} \right)
$$

$$
+ \frac{m}{4} \int_0^t \|\nabla s_t\|^2_{L^2(\Omega)}.
$$

Combining (3.38) and (3.39) we then find

$$
\frac{m}{2} \|s_t(t)\|^2_{L^2(\Omega)} + m \int_0^t \|\nabla s_t\|^2_{L^2(\Omega)}
$$

(3.40)

$$
\leq C + C \int_0^t \left( \|\tilde{\sigma}_t\|^2_{L^\infty(\Omega)} \|s\|^2_{L^4(\Omega)} \|s_t\|_{L^2(\Omega)} + \frac{m}{8} \int_0^t \|\nabla s_t\|^2_{L^2(\Omega)}
$$

$$
+ C \int_0^t \left( \|\tilde{\sigma}_t\|^2_{L^\infty(\Omega)} \|s\|^2_{L^4(\Omega)} \|s_t\|_{L^2(\Omega)} + \frac{m}{8} \int_0^t \|\nabla s_t\|^2_{L^2(\Omega)}
$$

$$
+ C \int_0^t \left( \|\tilde{\sigma}_t\|_{L^\infty(\Omega)} \|s_t\|_{L^2(\Omega)} + \|\tilde{\sigma}_t\|_{L^\infty(\Omega)} \|s\|_{L^2(\Omega)} \|s_t\|_{L^2(\Omega)} \right)
$$

$$
+ \frac{m}{4} \int_0^t \|\nabla s_t\|^2_{L^2(\Omega)}.
$$

Here, we have used the Young inequality, the trace theorem and the Sobolev injection once more. In addition note that, by (3.11), (3.14), and (3.32), from (3.40) we deduce

$$
\frac{m}{2} \|s_t(t)\|^2_{L^2(\Omega)} + \frac{m}{2} \int_0^t \|\nabla s_t\|^2_{L^2(\Omega)}
$$

(3.41)

$$
\leq C + C(R) + C \int_0^t \left( 1 + \|\tilde{\sigma}_t\|_{L^\infty(\Omega)} + \|s\|^2_{L^4(\Omega)} \|s_t\|^2_{L^2(\Omega)}
$$

$$
+ C \int_0^t \|\tilde{\sigma}_t\|_{L^\infty(\Omega)} \|s\|_{L^2(\Omega)} + \|s\|^2_{L^4(\Omega)} \|s_t\|_{L^2(\Omega)}
$$

Then we can apply the generalized Gronwall lemma, getting

$$
\|s_t\|_{L^\infty(0,T;L^2(\Omega))} \leq C(R),
$$

(3.42)
which, along with (3.41), gives
\[ \|s_t\|_{L^\infty(0,T;L^2(\Omega)) \cap L^2(0,T;H^1(\Omega))} \leq C(R). \tag{3.43} \]

Let us now rewrite equation (2.15) in the following form
\[ - \text{div} (\phi(\hat{c}) \nabla s) = -\phi(\hat{c})\hat{c}s - (\phi(\hat{c})s)_t, \tag{3.44} \]
and combine it with the boundary condition on \( \Gamma \times (0,T) \)
\[ \hat{c}_n s = -\frac{1}{\phi(\hat{c})} \nu(\hat{r})(s - \bar{s}). \tag{3.45} \]

We first observe that the right-hand side in (3.44) is bounded in \( L^\infty(0,T;L^2(\Omega)) \) and the right-hand side of (3.45) is bounded in \( L^\infty(0,T;H^{1/2}(\Gamma)) \) (see (2.3) and (3.32)). Thus, using standard elliptic regularity results (see, e.g., [15, Chap. 5]), we get
\[ \|s\|_{L^\infty(0,T;H^2(\Omega))} \leq C(R). \tag{3.46} \]

In order to prove that \( S : \mathcal{X}_{R,T} \to \mathcal{X}_{R,T} \), we have to show that \( s \geq 0 \) a.e. in \( (0,T) \times \Omega \) and \( \|s\|_{L^2(0,T;H^2(\Omega))} \leq R \). We deduce the positivity of \( s \) by applying a maximum principle argument (see, for instance, [14, Lemma 2.1]). Indeed \( s \) solves the problem
\[ \phi(\hat{c})s_t - \text{div} (\phi(\hat{c})\nabla s) + \phi(\hat{c})\hat{c}s = B\phi(\hat{c})\hat{c}s^2 \geq 0, \quad \text{in } \Omega, \tag{3.47} \]
\[ \phi(\hat{c})\hat{c}_n s + \nu(r)s_t = \nu(r)s \geq 0, \quad \text{on } \Gamma, \tag{3.48} \]
\[ s(0) = s_0 \geq 0, \quad \text{in } \Omega. \tag{3.49} \]

So that we have
\[ s(x,t) \geq 0, \quad \text{for a.e. } (x,t) \in \Omega \times (0,T). \tag{3.50} \]

Then, let us exploit (3.43) and (3.46) to get
\[ \|s\|_{L^\infty(0,T;L^2(\Omega)) \cap L^2(0,T;H^2(\Omega))} \leq T \|s_t\|_{L^\infty(0,T;L^2(\Omega))} + \|s_0\|_{L^2(\Omega)} + T^{1/2}\|s\|_{L^\infty(0,T;H^2(\Omega))} \]
\[ \leq (T + T^{1/2})C(R) + \|s_0\|_{L^2(\Omega)}. \tag{3.51} \]

Assuming \( \hat{T} \in (0,T] \) sufficiently small such that
\[ (\hat{T} + \hat{T}^{1/2})C(R) \leq R - \|s_0\|_{L^2(\Omega)}, \tag{3.52} \]
we infer
\[ \|s\|_{L^\infty(0,\hat{T};L^2(\Omega)) \cap L^2(0,\hat{T};H^2(\Omega))} \leq R, \tag{3.53} \]
so that \( \mathcal{S} : \mathcal{X}_{R,\hat{T}} \to \mathcal{X}_{R,\hat{T}} \). It is clear from the construction that a fixed point of \( \mathcal{S} \) is a local (in time) solution to our problem.

3.4. The contraction argument. Let us fix \( \hat{s}_i \in \mathcal{X}_{R,\hat{T}}, \ i = 1,2, \) and set \( \hat{c}_i = \mathcal{S}_1(\hat{s}_i), \ \hat{r}_i = \mathcal{S}_2(\hat{s}_i, \hat{c}_i) \) and \( s_i = \mathcal{S}_3(\hat{c}_i, \hat{r}_i) = \mathcal{S}(\hat{s}_i) \). We first estimate \( (\hat{c}_1 - \hat{c}_2) \) and \( (\hat{r}_1 - \hat{r}_2) \) in suitable norms. To this aim, let us first write (3.2) for \( i = 1,2, \) take the difference and test by \( \hat{c}_1 - \hat{c}_2 \). After integrating over \( (0,t) \) and using the Young inequality, we get (see (3.5))
\[ \frac{1}{2} \int_\Omega \left| (\hat{c}_1 - \hat{c}_2)(t) \right|^2 \tag{3.54} \]
\[ = - \int_0^t \int_\Omega \phi(\hat{c}_1)\hat{c}_1(\hat{s}_1 - \hat{s}_2)(\hat{c}_1 - \hat{c}_2) - \int_0^t \int_\Omega (\phi(\hat{c}_1)\hat{c}_1 - \phi(\hat{c}_2)\hat{c}_2)\hat{s}_2(\hat{c}_1 - \hat{c}_2) \]
Thus, due to (3.58), we can eventually deduce

\[ C \left( \int_0^T |\hat{s}_1 - \hat{s}_2|^2_{L^2(\Omega)} + |\hat{c}_1 - \hat{c}_2|^2_{L^2(\Omega)} + \int_0^T \|\hat{s}_2\|_{L^\infty(\Omega)} \|\hat{c}_1 - \hat{c}_2\|^2_{L^2(\Omega)} \right). \]

Using once more the generalized Gronwall lemma and the fact that \( |\hat{s}_2\|_{L^\infty(\Omega)} \) is bounded in \( L^2(0, \hat{T}) \) (see (3.46)), we obtain

\[ \|\hat{c}_1 - \hat{c}_2\|(t) \leq C(R) \|\hat{s}_1 - \hat{s}_2\|_{L^2(0, t; L^2(\Omega))}. \]  (3.55)

As a consequence, we deduce

\[ \|\hat{c}_1 - \hat{c}_2\|(t) \leq \|\phi(\hat{c}_1)\|_{L^\infty(\Omega)} \|\hat{s}_1 - \hat{s}_2\|_{L^2(0, t; L^2(\Omega))} + \int_0^t \|\hat{s}_2\|_{L^2(0, t; L^\infty(\Omega))} \|\hat{c}_1 - \hat{c}_2\|_{L^2(0, t; L^2(\Omega))} \]  (3.56)

\[ \leq C \left( \int_0^t \|\hat{s}_1 - \hat{s}_2\|_{L^2(0, t; L^2(\Omega))} + \|\hat{s}_2\|_{L^2(0, t; L^\infty(\Omega))} \|\hat{c}_1 - \hat{c}_2\|_{L^2(0, t; L^2(\Omega))} \right) \]  (3.57)

\[ \|\hat{c}_1 - \hat{c}_2\|(t) \leq C(R) \|\hat{s}_1 - \hat{s}_2\|_{L^2(0, t; L^2(\Omega))}. \]  (3.58)

Let us estimate \( \|\hat{c}_1 - \hat{c}_2\|_{L^2(0, \hat{T}; H^1(\Omega))} \). To this aim, we proceed by integrating the difference of equation (3.2) written for the two indices. This yields

\[ \|\hat{c}_1 - \hat{c}_2\|(t) \leq \int_0^t \|\phi(\hat{c}_1)\|_{L^\infty(\Omega)} \|\hat{s}_1 - \hat{s}_2\|_{H^1(\Omega)} \]  (3.59)

\[ \leq C \left( \int_0^t \|\hat{s}_1 - \hat{s}_2\|_{H^1(\Omega)} + \int_0^t \|\phi(\hat{c}_1)\|_{L^\infty(\Omega)} \|\hat{s}_1 - \hat{s}_2\|_{L^2(\Omega)} \right) \]  (3.60)
Consider now the two equations for \( s_1 \) and \( s_2 \). Subtracting the second from the first, we get
\[
(\phi(\hat{c}_1)t - (\phi(\hat{c}_2)t - \text{div}(\phi(\hat{c}_1)\nabla s_1 - \phi(\hat{c}_2)\nabla s_2)) = -\phi(\hat{c}_1)\hat{c}_1 s_1 + \phi(\hat{c}_2)\hat{c}_2 s_2.
\] (3.61)
Recalling the expression for \( \phi \), we obtain
\[
\phi(\hat{c}_1)(s_1 - s_2)_t + B(\hat{c}_1 - \hat{c}_2)(s_1 - s_2)_t + B(\hat{c}_1)(s_1 - s_2) + B(\hat{c}_1 - \hat{c}_2)s_2 = -\phi(\hat{c}_1)\hat{c}_1(s_1 - s_2) - (A(\hat{c}_1 - \hat{c}_2) + B(\hat{c}_1 - \hat{c}_2)(\hat{c}_1 + \hat{c}_2))s_2,
\] (3.62)
with the boundary condition
\[
\phi(\hat{c}_1)\hat{c}_n s_1 - \phi(\hat{c}_2)\hat{c}_n s_2 = -\nu(\hat{r}_1)(s_1 - \hat{s}) + \nu(\hat{r}_2)(s_2 - \hat{s}).
\] (3.63)
Testing (3.62) by \( s_1 - s_2 \) and integrating over \((0, t)\), we find
\[
\frac{1}{2} \int_0^t \int_\Omega \phi(\hat{c}_1) \frac{d}{dt} |s_1 - s_2|^2 + B \int_0^t \int_\Omega (\hat{c}_1 - \hat{c}_2)(s_1 - s_2)_t(s_1 - s_2) + \int_0^t \int_\Omega (\hat{c}_1 - \hat{c}_2)(s_1 - s_2)^2 + B \int_0^t \int_\Omega (\hat{c}_1 - \hat{c}_2) \nabla s_2 \nabla (s_1 - s_2) + \int_0^t \int_\Gamma \nu(\hat{r}_1)(s_1 - s_2)^2 + (\nu(\hat{r}_1) - \nu(\hat{r}_2))(s_2 - \hat{s})(s_1 - s_2) = -\int_0^t \int_\Omega \phi(\hat{c}_1)\hat{c}_1(s_1 - s_2)^2 - \int_0^t \int_\Omega (A(\hat{c}_1 - \hat{c}_2) + B(\hat{c}_1 - \hat{c}_2)(\hat{c}_1 + \hat{c}_2))s_2(s_1 - s_2).
\] (3.64)
Observe that
\[
\frac{1}{2} \int_0^t \int_\Omega \phi(\hat{c}_1) \frac{d}{dt} |s_1 - s_2|^2 = \frac{1}{2} \int_0^t \int_\Omega \phi(\hat{c}_1(t)) |(s_1 - s_2)(t)|^2 - \frac{1}{2} \int_0^t \int_\Omega B(\hat{c}_1)_t |s_1 - s_2|^2,
\] (3.65)
where
\[
\left| \frac{1}{2} \int_0^t \int_\Omega B(\hat{c}_1)_t |s_1 - s_2|^2 \right| \leq C \int_0^t \| (\hat{c}_1)_t \|_{L^\infty(\Omega)} \| s_1 - s_2 \|^2_{L^2(\Omega)},
\] (3.66)
and \( \| (\hat{c}_1)_t \|_{L^\infty(\Omega)} \) is bounded in \( L^2(0, \hat{T}) \) (see (3.11)). Then, it holds (see (3.11) and (3.32))
\[
|B \int_0^t \int_\Omega (\hat{c}_1 - \hat{c}_2)(s_1 - s_2)| \leq C \int_0^t \| (s_2)_t \|_{L^2(\Omega)} \| \hat{c}_1 - \hat{c}_2 \|_{L^4(\Omega)} \| s_1 - s_2 \|_{L^4(\Omega)}
\leq \delta \int_0^t \| s_1 - s_2 \|^2_{H^1(\Omega)} + C \int_0^t \| (s_2)_t \|^2_{L^2(\Omega)} \| \hat{c}_1 - \hat{c}_2 \|^2_{H^1(\Omega)}
\leq \delta \int_0^t \| s_1 - s_2 \|^2_{H^1(\Omega)} + C(R) \int_0^t \| (s_2)_t \|^2_{L^2(\Omega)} \| \hat{s}_1 - \hat{s}_2 \|^2_{L(0, R; H^1(\Omega))},
\] (3.67)
for a sufficiently small $\delta$ to be chosen later. Analogously, we have (see (3.56))

$$
\left| B \int_0^t \int_\Omega (\hat{c}_1 - \hat{c}_2) t s_2 (s_1 - s_2) \right| \leq C \int_0^t \|s_2\|_{L^\infty(\Omega)} \|\hat{c}_1 - \hat{c}_2\|_{L^2(\Omega)} \|s_1 - s_2\|_{L^2(\Omega)}
$$

$$
\leq \delta \|s_1 - s_2\|_{L^2(0,t;L^2(\Omega))}^2 + C \int_0^t \|\hat{c}_1 - \hat{c}_2\|_{L^2(\Omega)}
$$

$$
\leq \delta \|s_1 - s_2\|_{L^2(0,t;L^2(\Omega))}^2 + C(R) \|\hat{s}_1 - \hat{s}_2\|_{L^2(0,t;L^2(\Omega))}^2.
$$

(3.68)

The gradient terms are estimated using (3.58), namely,

$$
\left| B \int_0^t \int_\Omega (\hat{c}_1 - \hat{c}_2) \nabla s_2 \nabla (s_1 - s_2) \right|
$$

$$
\leq B \int_0^t \|\hat{c}_1 - \hat{c}_2\|_{L^4(\Omega)} \|\nabla s_2\|_{L^4(\Omega)} \|\nabla (s_1 - s_2)\|_{L^2(\Omega)}
$$

$$
\leq \delta \int_0^t \|s_1 - s_2\|_{H^1(\Omega)}^2 + C(R) \int_0^t \|\hat{s}_1 - \hat{s}_2\|_{L^2(0,t;H^1(\Omega))}^2.
$$

(3.69)

Observe that we can control the boundary term in this way

$$
\left| \int_0^t \int_G (\nu(\hat{r}_1) - \nu(\hat{r}_2))(s_2 - \bar{s})(s_1 - s_2) \right|
$$

$$
\leq |\nu'|_{L^\infty(\mathbb{R})} \int_0^t \|\hat{r}_1 - \hat{r}_2\|_{L^2(\Gamma)} \|s_2 - \bar{s}\|_{L^4(\Gamma)} \|s_1 - s_2\|_{L^4(\Gamma)}
$$

$$
\leq \delta \int_0^t \|s_1 - s_2\|_{H^1(\Omega)}^2 + C \int_0^t \|r_1 - r_2\|_{L^2(\Gamma)} \|s_2 - \bar{s}\|_{L^4(\Gamma)}^2
$$

$$
\leq \delta \int_0^t \|s_1 - s_2\|_{H^1(\Omega)}^2 + C(R) \int_0^t \|\hat{s}_1 - \hat{s}_2\|_{L^2(0,t;H^1(\Omega))}^2.
$$

(3.70)

Combining (3.64)–(3.70) and taking $\delta$ sufficiently small, we deduce

$$
\|s_1 - s_2\|_{L^2(\Omega)}^2 + \int_0^t \|s_1 - s_2\|_{H^1(\Omega)}^2
$$

$$
\leq C(R) \int_0^t (1 + \|(s_2)\|_{L^2(\Omega)}^2) \|\hat{s}_1 - \hat{s}_2\|_{L^2(0,t;H^1(\Omega))}^2
$$

$$
+ C(R) \|\hat{s}_1 - \hat{s}_2\|_{L^2(0,t;L^2(\Omega))}^2 + C \int_0^t \|\hat{s}_1 - \hat{s}_2\|_{L^2(0,t;L^2(\Omega))}^2.
$$

(3.71)

Finally, making use of the generalized Gronwall lemma, we get

$$
\|s_1 - s_2\|_{L^2(\Omega)}^2 + \int_0^t \|s_1 - s_2\|_{H^1(\Omega)}^2
$$

$$
\leq C(R) \left( \int_0^t \|\hat{s}_1 - \hat{s}_2\|_{L^2(\Omega)}^2 + \int_0^t \|\hat{s}_1 - \hat{s}_2\|_{L^2(0,t;H^1(\Omega))}^2 \right).
$$

(3.72)

Thus, for a suitable large $j \in \mathbb{N}$ (we recall that $R$ is fixed) we have that $S^j$ is a contraction in $X_{R,T}$. Hence, $S$ admits a unique fixed point $s$, which is the local in time solution to our original problem.
4. Global existence result for the initial problem. In this section, we show that (2.10) allows us to obtain a global a priori $L^\infty$ bound on $s$. Therefore, the previous fixed point argument can now be carried out without restriction on $T$ so that the unique fixed point is solution to our problem on the whole time interval $(0,T)$.

4.1. Uniform a priori bound for $s$. Assuming (2.10), let us prove that $s$ is globally bounded in $L^\infty(\Omega \times (0,T))$. Let us recall that (3.50) holds. Then, we introduce the auxiliary function

$$z(x,t) = S_0 - s(x,t), \quad \text{for a.e. } (x,t) \in \Omega \times (0,T),$$

and prove that $z$ solves the problem

$$\begin{align*}
(\phi(c)z)_t - \text{div}(\phi(c)\nabla z) + \phi(c)cz &= (\phi(c)c + \phi'(c)c_t)S_0, \quad \text{a.e. in } \Omega \times (0,T), \\
z(x,0) &= S_0 - s_0(x), \quad \text{in } \Omega, \\
\phi(c)\partial_{\nu}z + \nu(r)z|_{\Gamma} &= \nu(r)(S_0 - \bar{s}), \quad \text{a.e. on } \Gamma \times (0,T).
\end{align*}$$

Exploiting (2.17) (and (2.1)) we rewrite (4.2) as follows

$$\phi(c)z_t - \text{div}(\phi(c)\nabla z) + \phi(c)cz = (1 - BS_0) = S_0\phi(c)c(1 - BS_0).$$

Thanks to (2.10), we observe that

$$S_0\phi(c)c(1 - BS_0) \geq 0, \quad S_0 - s_0 \geq 0, \quad \nu(r)(S_0 - \bar{s}) \geq 0.$$  

Then we can apply once more [14, Lemma 2.1] and deduce that $z \geq 0$ in $\Omega \times (0,T)$. So that (see (3.50))

$$0 \leq s(x,t) \leq S_0, \quad \text{for a.e. } (x,t) \in \Omega \times (0,T).$$

4.2. Global a priori estimates. Here we show that using (4.6) and the uniform bound for $c = \hat{c}$ (see (3.5)), then $\|s\|_{L^\infty(0,T;H^2(\Omega))}$ is bounded by a constant depending only on the data.

First, we observe that (2.17) and (4.6) lead to a uniform estimate on $c_t$

$$\|c_t\|_{L^\infty(\Omega \times (0,T))} \leq C.$$  

Here $C$ also depends on $S_0$ (see (2.10)). Then, we can test (2.15) by $s$ and integrate over $(0,t)$. Arguing as in (3.19)–(3.20) we now deduce, in particular, that

$$\|s\|_{L^2(0,T;H^1(\Omega))} \leq C,$$

where now $C$ does not depend on $R$.

Integrating (2.17) with respect to time, and taking then the spatial gradient, we obtain the identity

$$\nabla c(t) = \nabla c_0 - \int_0^t (Bcs\nabla c + \phi(c)s\nabla c + \phi(c)c\nabla s).$$

By means of the previous estimates and the generalized Gronwall lemma we also get that

$$\|c\|_{L^\infty(0,T;H^1(\Omega))} \leq C,$$

where $C$ does not depend on $R$.

We can now argue as for (3.13), where the norms $\|s\|_{L^2(0,T;L^2(\Gamma))}$ and $\|c\|_{L^2(0,T;L^2(\Gamma))}$ are controlled by the norms in $\|s\|_{L^2(0,T;H^1(\Omega))}$, $\|c\|_{L^\infty(0,T;H^1(\Omega))}$, respectively. Thus, we obtain (replacing $\hat{r}$ with $r$)

$$\|r\|_{H^1(0,T;L^2(\Gamma))} \leq C.$$
for a constant $C$ independent of $R$.

Finally, recalling (3.43) and (3.46), we can find
\[ \| s \|_{W^{1,\infty}(0,T;L^2(\Omega))} + H^1(0,T;H^1(\Omega)) \cap L^\infty(0,T;H^2(\Omega)) \leq C, \]  
(4.10) for some $C$ independent of $R$.

Choosing now, in the fixed point argument, the constant $R > 0$ large enough such that $(T + T^{1/2})C + \| s_0 \|_{L^2(\Omega)} \leq R$, then we can prove that $S : X_{R,T} \to X_{R,T}$ is a contraction in $X_{R,T}$ so that the solution is defined on $(0, T)$.

5. Numerical examples. A fully implicit finite elements scheme has been used to solve numerically the proposed model where $s, c$ and $r$ are defined within the body or along the boundary $\Gamma$ of the domain $\Omega$. The evolution equation for $s$ (see (1.1)) is discretized with linear finite elements. The code is based on the freely available Open Source package deal.II [3].

Computational tests were performed to verify the efficiency of the numerical technique in 2D setup ($x = x_1e_1 + x_2e_2$). Moreover, these computations permit to illustrate the main features of the proposed approach. The considered domain is a simple marble square domain $1 \times 1 \text{mm}^2$ invested by a polluted air flow along the left vertical side whereas the other faces are isolated. The distribution of the pollutant $SO_2$ on the external border is constant with a concentration equal to $s_0$. Moreover, the material is homogeneous so that the initial condition for the calcite density reads $c(x, 0) = c_0$, being $c_0$ a positive constant, whereas the concentration of $SO_2$ within the solid is null so $s(x, 0) = 0$.

The numerical examples have been obtained by assuming simple expressions for the functions of (1.3), (1.4). In particular, according to the physical evidence that the higher is the rugosity value more exchange surface is available, two monotone relations have been considered for $\nu(r)$ with $r \geq 0$:

- linear $\nu(r) = \nu_0 + \frac{\nu_1 - \nu_0}{r_1} r$
- parabolic $\nu(r) = \nu_0 + \frac{\nu_1 - \nu_0}{r_1^2} r^2$

where the constants are

- $\nu_0$: the minimum value for a fully flat surface ($r = 0$)
- $\nu_1$: the maximum value when it is assumed that $r \in [0, r_1]$ (cf. Remark 2.3, setting $r_1 = R_0$).

The two curves give the same values of $\nu(r)$ for $r \in \{0, r_1\}$.

For simplicity, no constraints on the variable $r$ are introduced so to have $\partial W(r) = \Psi'(r) = 0$ and environmental sources are not considered thus $F = 0$. Under these hypotheses, equation (1.4) reduces to
\[ r_t + G(r, c, s) = 0, \quad \text{on } \Gamma \times (0, T). \]  
(5.1)

For the function $G(r, c, s)$ the following expression is adopted
\[ G(r, c, s) = -\varphi(c)s \left(1 + \frac{r}{1 + r}\right) g, \]  
(5.2)

being $g$ a parameter that defines the rate of rugosity evolution and has to be fitted according to experimental evidences.

In the numerical examples different initial rugosity distributions have been considered: piecewise constant or random distribution along the boundary. In both cases linear and parabolic diffusion functions for $\nu(r)$ have been adopted. Finally,
it has been assumed $\lambda = 100$, $g = 30$ and the time is discretized into $n$ constant time intervals $\Delta t = 1/5000$.

5.1. **Piecewise constant rugosity.** In the first example, piecewise constant value of the rugosity is assumed along the contour: for $x_2 < 0.5$, $r(x, 0) = 0.5r_0$ and for $x_2 \geq 0.5$, $r(x, 0) = 2r_0$ with $r_0$ a positive constant. In Figs. 1, 2, 3 are reported the profiles of the three variables $c, s, r$ along the vertical side invested by the pollutant $SO_2$ for several time steps. Both linear and parabolic evolution laws for $\nu(r)$ are considered.

The sulphation process reported in Fig. 1, due to the different assumed values of $r$, evolves with various velocities along the boundary. In fact, for small time step values, the profile of $c$ presents a significant gradient near $x_2 = 0.5$ where the rugosity is initially discontinuous. This phenomenon is much more evident in the parabolic relation for $\nu(r)$ is assumed. Subsequently, the solution becomes smoother and tends to be homogenous as $c \to 0$. This behavior can be understood analyzing the evolution of $s$ and $r$ as plotted in Figs. 2, 3 respectively. In fact, small rugosity values act as a barrier to the penetration of $s$. Even for these two variables high gradients are evident near the middle of the side. Indeed, the parabolic function for $\nu(r)$ reveals higher gradient values.

The effect of different rugosity values also influences the solution within the solids. The evolutions of the variables $c$ and $s$ are plotted along two horizontal lines located at $x_2 = (0.25, 0.75)$ for different time steps in Figs. 4, 5. At $x_2 = 0.25$, where the initial rugosity is high, the sulphation process is affected by the rapid diffusion of $s$ within the solid that activates the calcite transformation. On the contrary, the diffusion of $SO_2$ at $x_2 = 0.75$, and consequently the marble degradation, begins slowly due to the initial small value of $\nu(r)$. For large time steps ($n > 100$) the influence of the surface rugosity turns to be negligible on the inner solutions. The maps of $s$ within the solid is plotted in Fig. 6 for time steps $n = \{5, 15\}$ and parabolic $\nu(r)$. In the lower portion of the domain, due to higher rugosity values along the border, larger diffusion of $SO_2$ is evident.
5.2. Random rugosity. Subsequently, a random surface rugosity based on Weibull’s statistics is assigned on $\Gamma$. The initial value of $\bar{r}_0$ is therefore assumed as

$$\bar{r}_0 = r_0 \left( \ln \frac{1}{1 - \lambda} \right)^{1/m}$$

with $r_0$ and $m$ being, respectively, the Weibull shape and modulus parameters, and $\lambda$ a random variable ranging from 0 to 1. Here, $r_0$ is the mean value of surface rugosity. In the computation $m = 10$ has been considered. The initial rugosity profile is reported in Fig. 9 (the profile at timestep $n = 0$). In the evolution, the asperities are maintained for $\nu(r)$ linear whereas are emphasized in case of parabolic relation. For large time the rugosity does not evolve anymore and the heterogeneous profile is preserved.

The initial homogenous distribution of $c$ is abandoned during the sulphation process as clearly stated by Fig. 7 that reports the evolution of $c$ for $\nu(r)$ linear and parabolic. The profile becomes extremely jagged for parabolic relationship of
Figure 4. Evolution of $c$ along a horizontal line within the solid located at a) $x_2 = 0.25$ and b) $x_2 = 0.75$ assuming parabolic relationship for $\nu(r)$.

Figure 5. Evolution of $s$ along a horizontal line within the solid located at a) $x_2 = 0.25$ and b) $x_2 = 0.75$ assuming parabolic relationship for $\nu(r)$.

$\nu(r)$. Subsequently, the asperities vanish as $c \to 0$. Analogous behavior appears for the $SO_2$ concentration as reported in Fig. 8. During the sulphation process, the rugosity profile, as stated in Fig. 9, maintains the initial shape with an increment of the fluctuation.

6. Conclusions. The local in time well-posedness and the global existence theorem are preliminary but essential results related to our problem. A nontrivial issue might be the analysis of the longtime behavior of solutions and, in particular, their possible convergence to a steady state. Moreover, it would be interesting (and challenging) to extend our theoretical analysis to significant generalizations which account for further features of this complex phenomenon. In particular, in the coupling of bulk-surface equations, further actions should be taken into account, like the bulk damage and thermo-mechanical effects forcing the surface deterioration.
Figure 6. Concentration of $SO_2$ within the solid at different time step a) $n = 5$ and b) $n = 15$ assuming parabolic relationship for $\nu(r)$.

Figure 7. Evolution of $c$ along the left vertical bounder for $r$ random and $\nu(r)$ a) linear and b) parabolic.

The presented numerical simulations highlight the main features of the proposed model. The introduction of the superficial rugosity permits to account for an important physical property of the material that strongly influences initiation and the evolution of the sulphation stone subjected to pollutant. In fact, high rugosity values offers wider surface for the $SO_2$ diffusion that induces the sulphation process. On the other hand, extremely smooth surfaces slow down the degradation process.

At the present stage, two natural developments are possible. Firstly, an extensive experimental campaign has to be performed in order to fit the parameters of the proposed model and to define a proper function for $\nu(r)$. Secondly, the fracture phenomenon and mechanical degradation has to be coupled with the process of sulphation of the stones. In particular, the best candidate is the variational formulation of fracture mechanics that recently has gained much attention and demonstrated to be effective to determine complex crack paths [6].
