Abstract—A lattice is a set of all the integer linear combinations of certain linearly independent vectors. One of the most important concepts on lattice is the successive minima which is of vital importance from both theoretical and practical applications points of view. In this paper, we first study some properties of successive minima and then employ some of them to improve the suboptimal algorithm for solving an optimization problem about maximizing the achievable rate of the integer-forcing strategy for cloud radio access networks in [1].

Index Terms—Successive minima, integer-forcing, C-RAN.

I. INTRODUCTION

A lattice is a set of all the integer linear combinations of certain linearly independent vectors. Specifically, for any full column rank matrix \( \mathbf{A} \in \mathbb{R}^{m \times n} (m \geq n) \), the lattice \( \mathcal{L}(\mathbf{A}) \) generated by \( \mathbf{A} \) is defined by

\[
\mathcal{L}(\mathbf{A}) = \{ \mathbf{Ax} | x \in \mathbb{Z}^n \},
\]

and \( \mathbf{A} \) is called as the basis matrix of \( \mathcal{L}(\mathbf{A}) \), whose dimension is defined as the rank of \( \mathbf{A} \).

One of the most important concepts on lattice is the successive minima. Specifically, for any \( n \)-dimensional \( \mathcal{L}(\mathbf{A}) \), its \( i \)-th \((1 \leq i \leq n) \) successive minimum \( \lambda_i(\mathbf{A}) \) is defined as the smallest \( r \) such that the closed \( n \)-dimensional ball \( \mathcal{B}(0, r) \) of radius \( r \) centered at the origin contains \( i \) linearly independent lattice vectors.

Finding a vector whose length equals to a certain successive minimum is needed in a variety of applications. For example, in communications (see, e.g., [2]) and cryptography (see, e.g., [3]), one frequently needs to solve the following shortest vector problem (SVP) on \( \mathcal{L}(\mathbf{A}) \):

\[
\min_{x \in \mathbb{Z}^n \setminus \{0\}} \| \mathbf{Ax} \|_2,
\]

whose solution \( \mathbf{x} \) satisfies \( \| \mathbf{Ax} \|_2 = \lambda_1(\mathbf{A}) \). In some other applications, such as, integer-forcing (IF) linear receiver design [4], (after some transformations) one needs to solve a Shortest Independent Vector Problem (SIVP) on lattice \( \mathcal{L}(\mathbf{A}) \), i.e., finding an invertible matrix \( \mathbf{X} = [\mathbf{x}_1, \ldots, \mathbf{x}_n] \in \mathbb{Z}^{n \times n} \) such that

\[
\max_{1 \leq i \leq n} \| \mathbf{Ax}_i \|_2 \leq \lambda_n(\mathbf{A}).
\]

A closely related problem to the SIVP is a Successive Minima Probem (SMP), i.e., finding an invertible matrix \( \mathbf{X} = [\mathbf{x}_1, \ldots, \mathbf{x}_n] \in \mathbb{Z}^{n \times n} \) such that

\[
\| \mathbf{Ax}_i \|_2 = \lambda_i(\mathbf{A}), \quad i = 1, 2, \ldots, n.
\]

Solving an SMP is needed in some practical applications, such as physical-layer network coding [5], the expanded compute-and-forward framework [6] and IF source coding [7].

Cloud radio access networks (C-RANs) is a promising framework for 5G wireless communication systems. Recently, an IF framework with two architectures for uplink C-RANs has been proposed in [1]. Simulations in [1] indicate that for the scenario where channel state is available to the receivers only, the two architectures can nearly match and often outperforms Wyner-Ziv-based strategies, respectively.

Successive minima is of vital importance from both theoretical and application points of view. Thus, this paper aims to develop some properties of successive minima. Some of them are useful for IF design for uplink C-RANs.

The rest of the paper is organized as follows. We develop some properties of successive minima in Section II and use some of them to improve the suboptimal algorithm for IF design for C-RAN in [1] in Section III. Finally, conclusions are given in Section IV.

Notation. Let \( \mathbb{R}^{m \times n} \) and \( \mathbb{Z}^{m \times n} \) respectively stand for the space of the \( m \times n \) real and integer matrices. Let \( \mathbb{R}^n \) and \( \mathbb{Z}^n \) denote the space of the \( n \)-dimensional real and integer column vectors, respectively. For a symmetric positive definite (SPD) matrix \( \mathbf{G} \in \mathbb{R}^{n \times n} \), we use \( \text{chol}(\mathbf{G}) \) to denote the Cholesky factor of \( \mathbf{G} \). For a matrix \( \mathbf{A} \), let \( a_{ij} \) denote its element at row \( i \) and column \( j \), \( a_i \) be its \( i \)-th column. For a vector \( \mathbf{x} \), let \( x_i \) be its \( i \)-th element.

II. SOME PROPERTIES OF SUCCESSIVE MINIMUM

In this section, we first develop the monotonic property of successive minima. Then, we propose a lower and an upper bound on them. Some of these properties will be used in the next section for IF design for C-RAN.

To prove our proposed properties of successive minima, we need to introduce the following well-known property of successive minima:

\[
\lambda_1(\mathbf{A}) \leq \lambda_2(\mathbf{A}) \leq \cdots \leq \lambda_n(\mathbf{A})
\]
for any full column rank matrix $A \in \mathbb{R}^{m \times n}$. In fact, (4) can be easily seen from the definition of successive minima.

A. Monotonic property of successive minima

In the following, we develop some properties of successive minima. Since in communications, it is often that one needs to solve an SMP on a lattice whose basis matrix is not explicitly given, but is the Cholesky factor of an SPD matrix, in the sequel, we develop some properties of successive minima of some lattices whose bases matrices are the Cholesky factors of some SPD matrices.

**Theorem 1.** Suppose that $G_1, G_2 \in \mathbb{R}^{n \times n}$ are SPD matrices. Denote

$$R_1 = \text{chol}(G_1), \quad R_2 = \text{chol}(G_2), \quad R_3 = \text{chol}(G_1 + G_2).$$

Then, for $i = 1, 2, \ldots, n$, we have

$$\lambda_i(R_3) \geq \max \left\{ \sqrt{\lambda_i^2(R_1) + \lambda_i^2(R_2)}, \sqrt{\lambda_i^2(R_2) + \lambda_i^2(R_1)} \right\}.$$  \hspace{1cm} (5)

**Proof.** Since both $G_1$ and $G_2$ are SPD matrices, $G_1 + G_2$ is also an SPD matrix. Hence, $R_3 = \text{chol}(G_1 + G_2)$ is an invertible matrix, implying that $\mathcal{L}(R_3)$ is well-defined.

To show (5), it is equivalent to show

$$\lambda_i(R_3) \geq \sqrt{\lambda_i^2(R_1) + \lambda_i^2(R_2)}$$  \hspace{1cm} (6)

and

$$\lambda_i(R_3) \geq \sqrt{\lambda_i^2(R_2) + \lambda_i^2(R_1)}.$$  \hspace{1cm} (7)

In the following, we only prove (6) since (7) can be similarly proved.

Since the solution of the SMP on $\mathcal{L}(R_3)$ (see (5)) always exists, there exists an invertible matrix $X = [x_1, \ldots, x_n] \in \mathbb{Z}^{n \times n}$ such that

$$\|R_3 x_i\|_2 = \lambda_i(R_3), \quad i = 1, 2, \ldots, n,$$

which combing with $R_3 = \text{chol}(G_1 + G_2)$ implies that

$$x_i^\top (G_1 + G_2) x_i = \lambda_i^2(R_3), \quad i = 1, 2, \ldots, n.$$

Let

$$j = \arg \max_{1 \leq k \leq i} x_k^\top G_1 x_k.$$  \hspace{1cm} (8)

Then, according to (4), we have

$$\lambda_i^2(R_3) \geq \lambda_j^2(R_3) = x_j^\top G_1 x_j + x_j^\top G_2 x_j.$$  \hspace{1cm} (9)

Since $X$ is invertible, $x_1, \ldots, x_i$ are linearly independent, so are $Rx_1, \ldots, Rx_i$. Then, by (5) and the definition of successive minima, one can see that

$$x_j^\top G_1 x_j = \|R_j x_j\|_2^2 \geq \lambda_j^2(R_1).$$  \hspace{1cm} (10)

Since $G_2$ is an SPD matrix, $R_2$ is invertible. Then by the definition of successive minima and the fact that $x_j$ is a nonzero integer vector, we can see that

$$x_j^\top G_2 x_j = \|R_2 x_j\|_2^2 \geq \lambda_j^2(R_2).$$

Hence, (6) follows from the above three equations.

**Remark 1.** Note that it is not necessary that both $G_1$ and $G_2$ are SPD matrices in Theorem 1. In fact, one of them is an SPD matrix and the other one is a non-invertible symmetric positive semidefinite matrix is enough. More specifically, if $G_1$ is an SPD matrix and $G_2$ is a non-invertible symmetric positive semidefinite matrix, then (5) is reduced to $\lambda_i(R_3) \geq \lambda_i(R_1)$. Similarly, if $G_2$ is an SPD matrix and $G_1$ is a non-invertible symmetric positive semidefinite matrix, then (5) is reduced to $\lambda_i(R_3) \geq \lambda_i(R_2)$.

We would like to point out that the equality in (5) is achievable. For more details, see the following example.

**Example 1.** Suppose that $\alpha_1, \alpha_2, \ldots, \alpha_n$ satisfy

$$0 < \alpha_1 \leq \alpha_2 \leq \cdots \leq \alpha_n.$$  \hspace{1cm} (9)

Let $G_1$ be a diagonal matrix with its diagonal entries being $\alpha_1, \alpha_2, \ldots, \alpha_n$, i.e., $G_1 = \text{diag}(\alpha_1, \alpha_2, \ldots, \alpha_n)$. $G_2 = \beta I$ for some $\beta > 0$.

Then

$$R_1 = \text{diag}(\sqrt{\alpha_1}, \sqrt{\alpha_2}, \ldots, \sqrt{\alpha_n}), \quad R_2 = \sqrt{\beta} I,$$

$$R_3 = \text{diag}(\sqrt{\alpha_1 + \beta}, \sqrt{\alpha_2 + \beta}, \ldots, \sqrt{\alpha_n + \beta})$$

which combing with (6) implies that

$$\lambda_i(R_1) = \sqrt{\alpha_i}, \quad \lambda_i(R_2) = \sqrt{\beta}, \quad \lambda_i(R_3) = \sqrt{\alpha_i + \beta}$$

for $i = 1, 2, \ldots, n$.

Hence,

$$\lambda_i^2(R_1) + \lambda_i^2(R_2) \geq \sqrt{\alpha_i + \beta} = \sqrt{\lambda_i^2(R_2) + \lambda_i^2(R_1)}.$$

Thus, the equality in (5) is reached.

By using Theorem 1 we can prove the following theorem which provides an upper bound on the successive minima of a lattice whose basis matrix is given by the Cholesky factor of the inverse of the sum of two SPD matrices.

**Theorem 2.** Suppose that $G_1, G_2 \in \mathbb{R}^{n \times n}$ are SPD matrices. Denote $R_1 = \text{chol}(G_1^{-1}), \quad R_2 = \text{chol}(G_2^{-1}), \quad R_3 = \text{chol}(G_1 + G_2)^{-1}$ and

$$\hat{R}_4 = \text{chol}(G_1^{-1}(G_1^{-1} + G_2^{-1})^{-1} G_1^{-1}), \quad \hat{R}_5 = \text{chol}(G_2^{-1}(G_1^{-1} + G_2^{-1})^{-1} G_2^{-1}).$$

Then, for $i = 1, 2, \ldots, n$, we have

$$\lambda_i(R_1) \geq \max \left\{ \sqrt{\lambda_i^2(R_3) + \lambda_i^2(R_4)}, \sqrt{\lambda_i^2(R_4) + \lambda_i^2(R_5)} \right\},$$  \hspace{1cm} (10)

$$\lambda_i(R_2) \geq \max \left\{ \sqrt{\lambda_i^2(R_3) + \lambda_i^2(R_5)}, \sqrt{\lambda_i^2(R_5) + \lambda_i^2(R_4)} \right\}. $$  \hspace{1cm} (11)

**Proof.** By the Woodbury matrix identity, we have

$$(G_1 + G_2)^{-1} = G_1^{-1} - G_1^{-1}(G_1^{-1} + G_2^{-1})^{-1} G_1^{-1},$$

$$(G_1 + G_2)^{-1} = G_2^{-1} - G_2^{-1}(G_1^{-1} + G_2^{-1})^{-1} G_2^{-1}.$$
Then
\[ G_1^{-1} = (G_1 + G_2)^{-1} + G_1^{-1}G_2^{-1} - G_1^{-1}G_1^{-1}G_2^{-1}, \quad \text{(12)} \]
\[ G_2^{-1} = (G_1 + G_2)^{-1} + G_2^{-1}G_1^{-1} - G_2^{-1}G_2^{-1}G_1^{-1}. \]

Since both $G_1$ and $G_2$ are SPD matrices, so are $G_1^{-1}, G_2^{-1}, (G_1 + G_2)^{-1}, G_1^{-1}G_2^{-1} - G_1^{-1}G_1^{-1}G_2^{-1}$ and $G_2^{-1}G_1^{-1}G_2^{-1} - G_2^{-1}G_2^{-1}G_1^{-1}G_2^{-1}$. Hence, (10) and (11) follow from (5).

We would like to point out that the equalities in (10) and (11) are achievable. For more details, see the following example.

**Example 2.** Let $G_1 = \text{diag}(\alpha_1, \alpha_2, \ldots, \alpha_n)$ for $\alpha_1, \alpha_2, \ldots, \alpha_n$ satisfying (9), $G_2 = \beta I - G_1$ for some $\beta > 0$. In the following, we show that both the equalities in (10) and (11) are achievable. By some direct calculations, we have
\[ \hat{R}_1 = \text{diag} \left( \frac{1}{\sqrt{\alpha_1}}, \frac{1}{\sqrt{\alpha_2}}, \ldots, \frac{1}{\sqrt{\alpha_n}} \right), \quad \hat{R}_3 = \frac{1}{\sqrt{\beta}} I, \]
\[ \hat{R}_2 = \text{diag} \left( \frac{1}{\sqrt{\beta - \alpha_1}}, \frac{1}{\sqrt{\beta - \alpha_2}}, \ldots, \frac{1}{\sqrt{\beta - \alpha_n}} \right), \]
\[ \hat{R}_4 = \text{diag} \left( \frac{1}{\alpha_1 - \beta}, \frac{1}{\alpha_2 - \beta}, \ldots, \frac{1}{\alpha_n - \beta} \right), \]
\[ \hat{R}_5 = \frac{1}{\sqrt{\beta}} \text{diag} \left( \frac{\sqrt{\alpha_1}}{\sqrt{\beta - \alpha_1}}, \frac{\sqrt{\alpha_2}}{\sqrt{\beta - \alpha_2}}, \ldots, \frac{\sqrt{\alpha_n}}{\sqrt{\beta - \alpha_n}} \right). \]

Then, by (9), for $i = 1, 2, \ldots, n$, we have
\[ \lambda_i(\hat{R}_1) = \frac{1}{\sqrt{\alpha_i - 1}}, \quad \lambda_i(\hat{R}_2) = \frac{1}{\sqrt{\beta - \alpha_i}}, \quad \lambda_i(\hat{R}_3) = \frac{1}{\sqrt{\beta}}, \]
\[ \lambda_i(\hat{R}_4) = \sqrt{\frac{\alpha_i}{\alpha_i - 1} - \frac{1}{\beta}}, \quad \lambda_i(\hat{R}_5) = \sqrt{\frac{\alpha_i}{\alpha_i - 1} - \frac{1}{\beta}}. \]

By some simple calculations, one can easily show that both the equalities in (10) and (11) are reached.

**Remark 2.** It is worth pointing out that (5), (10) and (11) cannot be generalized to $i > 1$, i.e., none of the following inequalities
\[ \lambda_i(R_1) \geq \sqrt{\lambda_i^2(R_1) + \lambda_i^2(R_2)}, \]
\[ \lambda_i(R_1) \geq \sqrt{\lambda_i^2(R_3) + \lambda_i^2(R_4)}, \]
\[ \lambda_i(R_1) \geq \sqrt{\lambda_i^2(R_5) + \lambda_i^2(R_6)}. \]
always hold. Indeed, the following example shows this.

**Example 3.** Let
\[ G_1 = \begin{bmatrix} 3 & 0 \\ 0 & 1 \end{bmatrix}, \quad G_2 = \begin{bmatrix} 1 & 0 \\ 0 & 8 \end{bmatrix}. \]

Then
\[ R_1 = \begin{bmatrix} \sqrt{3} & 0 \\ 0 & 1 \end{bmatrix}, \quad R_2 = \begin{bmatrix} 1 & 0 \\ 0 & \sqrt{8} \end{bmatrix}, \quad R_3 = \begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix} \]

which implies that
\[ \lambda_2(R_1) = \sqrt{3}, \quad \lambda_2(R_2) = \sqrt{8}, \quad \lambda_2(R_3) = 3. \]

Then, one can see that
\[ \lambda_2(R_1) < \sqrt{\lambda_2^2(R_1) + \lambda_2^2(R_2)}. \]

Furthermore, by some simple calculations, one can easily show that
\[ \lambda_2(R_1) < \sqrt{\lambda_2^2(R_3) + \lambda_2^2(R_4)}, \]
\[ \lambda_2(R_2) < \sqrt{\lambda_2^2(R_5) + \lambda_2^2(R_6)}. \]

From Theorems 1 and 2 one immediately obtains the following monotonic property of successive minima.

**Corollary 1.** Let $G_1, G_2 \in \mathbb{R}^{n \times n}$ be SPD matrices such that $G_1 - G_2$ is also an SPD matrix. Let $R_1, R_2$ and $R_1, R_2$ be defined as in Theorems 1 and 2 then for $i = 1, 2, \ldots, n$, we have
\[ \lambda_i(R_1) > \lambda_i(R_2), \quad \lambda_i(\hat{R}_1) < \lambda_i(\hat{R}_2). \]

From Corollary 1 we have the following result which shows that the monotonic property of successive minima keeps unchanged by adding a symmetric positive semidefinite matrix and/or left multiplying a full column rank matrix followed by right multiplying the transpose of this matrix.

**Corollary 2.** Let $G_1, G_2 \in \mathbb{R}^{n \times n}$ be SPD matrices such that $G_1 - G_2$ is also SPD. Let $G \in \mathbb{R}^{m \times n}$ be an arbitrary symmetric positive semidefinite and $B \in \mathbb{R}^{m \times m}$ be an arbitrary full column rank matrix. Denote
\[ R_1 = \text{chol}(G + B^T G_1 B), \quad R_2 = \text{chol}(G + B^T G_2 B), \]
\[ R_3 = \text{chol}(G + B^T G_1^{-1} B), \quad R_4 = \text{chol}(G + B^T G_2^{-1} B) \]

and
\[ \hat{R}_1 = \text{chol}((G + B^T G_1 B)^{-1}), \]
\[ \hat{R}_2 = \text{chol}((G + B^T G_2 B)^{-1}), \]
\[ \hat{R}_3 = \text{chol}((G + B^T G_1^{-1} B)^{-1}), \]
\[ \hat{R}_4 = \text{chol}((G + B^T G_2^{-1} B)^{-1}). \]

Then
\[ \lambda_i(R_1) > \lambda_i(R_2), \quad \lambda_i(\hat{R}_1) < \lambda_i(\hat{R}_2), \]
\[ \lambda_i(R_3) < \lambda_i(R_4), \quad \lambda_i(\hat{R}_3) > \lambda_i(\hat{R}_4). \]

**Proof.** Since both $G_1$ and $G_2$ are SPD, $G$ is symmetric positive semidefinite and $B$ is a full column rank matrix, one can see that both $G + B^T G_1 B$ and $G + B^T G_2 B$ are also SPD. Moreover, $G_1 - G_2$ is SPD, implying that
\[ G + B^T G_1 B - (G + B^T G_2 B) = B^T (G_1 - G_2) B \]
is also SPD. Thus, (14) follows from (13).

In the following, we show (15). By (14), we only need to show that $G_2^{-1} - G_1^{-1}$ is an SPD matrix. Let $G_3 = G_1 - G_2$, then by the assumption, $G_3$ is an SPD matrix. Then, by (12), we have
\[ G_2^{-1} = (G_2 + G_3)^{-1} + G_2^{-1}(G_2^{-1} + G_3^{-1})^{-1} G_2^{-1}, \]
which implies that $G_2^{-1} - G_1^{-1}$ is an SPD matrix and hence (15) holds.
B. Approximating the successive minima

In this subsection, we propose a lower and an upper bound on the successive minima.

Let $R \in \mathbb{R}^{n \times n}$ be the R-factor of the QR factorization of a full column rank matrix $A$ or a Cholesky factor of an SPD matrix $G$, then we have the following result which gives a lower and an upper bound on the successive minima of $L(R)$.

**Proposition 1.** For $i = 1, 2, \ldots, n$, we have

$$
\min_{1 \leq j \leq n} |r_{ij}| \leq \lambda_i(R) \leq \max_{1 \leq j \leq i} \|R_{1:j, 1:j}\|_2.
$$

**Proof.** The second inequality is well-known and can be seen from the definition of successive minima.

The first inequality follows from (4) and the fact that $\lambda_i(R) \geq \min_{1 \leq j \leq n} |r_{ij}|$.

For the sake of readability, in the following, we recall its proof from [9]. Let $x \in \mathbb{Z}^n$ such that $\lambda_1(R) = \|Rx\|_2$ and suppose that the last nonzero entry of $x$ is $x_i$, then clearly $\lambda_1(R) \geq |r_{ii}x_i| \geq |r_{ii}|$. Hence $\lambda_1(R) \geq \min_{1 \leq j \leq n} |r_{ij}|$ holds.

**Remark 3.** Note that both of the inequalities in (16) are achievable. For example, if $R = \alpha I$ for some $\alpha > 0$, then one can easily see that for $i = 1, 2, \ldots, n$,

$$
\alpha = \min_{1 \leq j \leq n} |r_{ij}| = \lambda_i(R) = \max_{1 \leq j \leq i} \|R_{1:j, 1:j}\|_2.
$$

**Remark 4.** The first inequality in (16) can be slightly improved when $i = n$. Specifically, we have $\lambda_n(R) \geq \sqrt{\det(R)}$. In fact, by [7] Proposition 2], we have $\prod_{i=1}^n \lambda_i(R) \geq \det(R)$, which combining with (4) implies the above inequality.

Note that the bounds given by (16) will become sharper if we use the information of $R$ to give the upper bound, where $R$ is a lattice reduced upper triangular matrix of $R$. Some of the commonly used lattice reduction strategies to achieve this purpose include the LLL reduction [9], KZ reduction [10] [11] and Minkowski reduction [12].

By Theorem 1 Proposition 1 and Remark 2 one can easily see the following result:

**Corollary 3.** Let $G_1, G_2 \in \mathbb{R}^{n \times n}$ be SPD matrices such that $G_1 - G_2$ is also an SPD matrix. Let $R_1, R_2, R_3$ be defined as in Theorem 1 then for $i = 1, 2, \ldots, n - 1$, we have

$$
\lambda_i(R_3) \geq \min_{1 \leq j \leq n} \left( \frac{(r_{ij}^{(1)})^2 + \lambda_j^2(R_2)}{\sqrt{(r_{ij}^{(2)})^2 + \lambda_j^2(R_1)}} \right)
$$

and

$$
\lambda_n(R_3) \geq \min \left\{ \frac{\det(R_1)^{2/n} + \lambda_n^2(R_2)}{\det(R_2)^{2/n} + \lambda_n^2(R_1)} \right\},
$$

where $r_{ij}^{(1)}$ and $r_{ij}^{(2)}$ are the $j$-th diagonal entries of $R_1$ and $R_2$, respectively.

III. IMPROVING IF DESIGN FOR C-RAN

An algorithm for suboptimally solving an optimization problem about maximizing the achievable symmetric rate for the IF strategy with parallel channel decoding and parallel decompression for C-RAN has been proposed in [1]. In this section, we will use some properties of successive minima, that were developed in Sec. II, to improve its efficiency.

C-RAN is a promising framework for 5G wireless communication systems. An end-to-end IF architecture for C-RAN has been proposed in [1]. In this section, we will use some properties of successive minima, that were developed in Sec. II, to improve its efficiency.

By Corollary 2 and (19), thus the smallest $d$ satisfies

$$
\min_{X \in \mathbb{Z}^{n \times n}, \det(X) \neq 0} \max_{1 \leq i \leq n} 2 \log^+ (\|F(d)x_i\|_2) = C
$$

is the desired $d$. In fact, by the definition of successive minima, (18) is equivalent to $\lambda_n(F(d)) \leq \exp(2C)$. By Corollary 2 and (20), one can see that $\lambda_n(F(d))$ is decreasing with $d$. 

Thus, the desired $d$ is the one satisfies (22). After finding $d$ and explicitly forming $F(d)$, the LLL reduction is used to find a suboptimal $X$. A bisection search method coupled with the LLL reduction on $F(d)$ has been proposed in [11] to find an approximation solution of (22) to get a suboptimal $d$. The bisection method is initialized by setting $d_{\min} = 0$ and $d_{\max}$ large enough such that (18) holds as in [1].

In the following, we improve this suboptimal algorithm. First, instead of using the LLL reduction, for efficiency, we use the PLLL reduction which was proposed in [12] followed by size reduction. The latter has the same performance as the former in this application, but it is around $O(n)$ times faster than the former. Second, instead of setting $d_{\min} = 0$ and $d_{\max}$ large enough such that (18) holds as in [1], we use a larger $d_{\min}$ and explicitly giving $d_{\max}$. More details on this are giving as follows.

By the above analysis, finding the smallest $d$ is equivalent to solving $\lambda_n(\tilde{F}(d)) = \exp(2C)$. Since $\lambda_n(\tilde{F}(d))$ is decreasing with $d$, to use the bisection method to find the desired $d$, we need to find $d_{\min}$ and $d_{\max}$ such that $\lambda_n(\tilde{F}(d_{\min})) \geq \exp(2C)$ and $\lambda_n(\tilde{F}(d_{\max})) \leq \exp(2C)$, respectively. To this end, we denote

$$G = \text{chol}(PBH(\hat{HB}^\top + BB^\top)), \quad \tilde{F} = \text{chol}(G).$$

Then, by (20), (23) and Corollary 3, we have

$$\lambda_n(\tilde{F}(d)) \geq \sqrt{|\det(d^{-1/2}\tilde{F})|^2/n + 1} = \sqrt{|d^{-1}|\det(\tilde{F})|^2/n + 1}. \tag{24}$$

Let $d_{\min}$ be the solution of

$$\sqrt{|d^{-1}|\det(\tilde{F})|^2/n + 1} = \exp(2C),$$

then by (24), $d_{\min}$ satisfies $\lambda_n(\tilde{F}(d_{\min})) \geq \exp(2C)$.

By performing the PLLL reduction (see [12]) followed by size reduction on $\tilde{F}$ to find an unimodula matrix $Z$ (i.e., $Z \in \mathbb{Z}^{n \times n}$ such that $|\det(Z)| = 1$) such that $\tilde{F}Z$ is LLL reduced, then $d^{-1/2}\tilde{F}Z$ is also LLL reduced for any $d > 0$. Let $d_{\max}$ be the solution of

$$\sqrt{\max_{1 \leq i \leq n} Z_i^\top(d^{-1}G + I)Z_i} = \exp(2C).$$

then by the definition of $\lambda_n$, one can see that $\lambda_n(\tilde{F}(d_{\max})) \leq \exp(2C)$.

IV. CONCLUSION

The successive minima of a lattice is important in both communications and cryptography. In this paper, we investigated some properties of successive minima and then employed some of them to improve the efficiency of the suboptimal algorithm for solving an optimization problem about maximizing the achievable rate of the IF for C-RANs in [1].
