Abstract

The contribution of the tensor interaction in Hartree–Fock calculation for closed shell nuclei is studied. The investigation is done neglecting the spin–orbit component of the force. As expected from nuclear matter estimates we find that the effect of the tensor interaction is negligible in the case of spin–isospin saturated nuclei and also for medium and heavy nuclei with closed shells. In light nuclei with only one of the two spin–orbit partners filled, such as $^{12}\text{C}$ and $^{14}\text{C}$, the tensor interaction plays an important role.

PACS 21.60.Jz
1 Introduction

One of the peculiarities of the nucleon–nucleon interaction is the presence of non-central terms. Already at the beginning of the 40’s the existence of a quadrupole moment of the deuteron was recognized [1]. This fact was explained by Rarita and Schwinger in terms of a static tensor force [2]. The presence of tensor terms is an essential ingredient in the modern phase–shift analysis of nucleon–nucleon scattering data [3]. In a meson exchange picture of the nucleon–nucleon interaction, tensor terms arise already when the exchange of the lightest and better known meson, the pion, is considered.

The relevance of the tensor part of the nucleon-nucleon interaction is not only restricted to two–body systems. Calculations based on microscopic nucleon–nucleon interactions of light and medium–heavy nuclei [4] and nuclear matter [5] show that binding is obtained only because of the presence of the tensor force.

Although the tensor terms of the interactions are essential in microscopic calculations, they are usually neglected in effective theories where the Schrödinger equation is solved at the mean–field level, since their contribution is though to be small. This attitude is not unreasonable if one consider that the tensor terms of the interactions do not contribute in mean–field calculations of the binding energy of symmetric nuclear matter. On the other hand, since the spin and isospin structure of finite nuclei is richer than that of nuclear matter, one may expect to find, in the former systems some observable sensitive to the presence of the tensor terms of the interaction. In this respect Random Phase Approximation calculations have shown that magnetic excitations can be reasonably described only when tensor terms are included in the effective interaction [6].

We have investigated the effects of the tensor terms of the nucleon-nucleon interaction on ground state properties of doubly–magic nuclei and in this work we would like to answer the question whether it is reasonable to neglect this part of the interaction in Hartree–Fock calculations. We started our study by using a well known finite range interaction, the Brink and Boeker B1 force [7], defined only in the four central components. To this basic interaction we have added the tensor and tensor–isospin terms taken from the realistic Argonne \( v_{14} \) potential [8] and from the phenomenological Jülich–Stony Brook (JSB) interaction [9]. Our investigation consists in comparing the results obtained with these three different interactions for various closed shell nuclei.

We briefly describe the formalism in the next section and we present the results of our investigation in Sect. 3. We shall show and explain the fact that the contribution of the tensor interaction is negligible for those nuclei where all the spin–orbit partners single particle levels are occupied. For the other nuclei, these contributions remains small if the nuclei are heavy.

2 The formalism

The Hartree–Fock (HF) equations are obtained searching for a minimum of the energy functional within a Hilbert space restricted to states which are Slater determinant of single
particle (sp) wave functions. In this way the many–body problem is transformed in a set of many one–body problems. For hamiltonians containing only two–body interactions, without explicit density dependent terms, one has to solve, in coordinate space, a set of equations of the type:

$$-\frac{\hbar^2}{2m_k} \nabla_1^2 \phi_k(r_1) + U(r_1) \phi_k(r_1) - \int d^3 r_2 W(r_1, r_2) \phi_k(r_2) = \epsilon_k \phi_k(r_1), \quad (1)$$

where we have indicated with $k$ the set of quantum numbers characterizing the sp wave function $\phi_k$ and the sp energy $\epsilon_k$. The two quantities $U$ and $W$ are the standard Hartree and Fock–Dirac potentials.[9]

The only input of the theory is the effective nucleon–nucleon interaction which we have chosen as a six components finite–range two–body force of the type:

$$V(r_1, r_2) = \sum_{p=1}^{6} V_p(r_1, r_2) O_p(1, 2) \quad (2)$$

where $O_p(1, 2)$ indicates the following operators 1, $\tau_1 \cdot \tau_2$, $\sigma_1 \cdot \sigma_2$, $\sigma_1 \cdot \tau_2$, $\tau_1 \cdot \tau_2$, $S_{12}$, $S_{12} \tau_1 \cdot \tau_2$, for $p = 1, \ldots, 6$, respectively. In this expression we have adopted the usual convention for the tensor operator:

$$S_{12} = 3 \frac{(\sigma_1 \cdot r_{12})(\sigma_2 \cdot r_{12})}{(r_{12})^2} - \sigma_1 \cdot \sigma_2, \quad (3)$$

with $r_{12} = r_1 - r_2$.

We suppose that all the functions $V_p$ in eq. (B) depend only from the relative distance between the two particles, $|r_{12}|$. It is therefore convenient to use expressions of the sp wave functions where the angular and radial coordinates are separated:

$$\phi_k(r) \equiv \phi_{nljm}^{(1)}(r) \equiv \frac{u^l_{nlj}(r)}{r} |ljmt\rangle$$

$$\equiv \frac{u^l_{nlj}(r)}{r} \sum_{\mu s} \langle ljmt | Y_{l\mu}(\theta, \varphi) \rangle \chi_s \chi_t.$$  \quad (4)

In the above expression $\theta$ and $\varphi$ are the angular coordinates, $Y_{l\mu}$ is a spherical harmonics, $\chi_s$ and $\chi_t$ are the spin and isospin wave functions, $s$ and $t$ represent the third components of spin and isospin, and $\langle ljmt | \frac{1}{2} s | j m \rangle$ is a Clebsh–Gordan coefficient.

Multiplying eq. (4) by $\langle l_k j_k m_k t_k |$ and integrating on the angular, spin and isospin variables we obtain:

$$-\frac{\hbar^2}{2m_k} \left( \frac{d^2}{dr^2} - \frac{l_k(l_k + 1)}{r^2} \right) u^{t_k}_{nlkj}(r) + U^{t_k}_{nlkj}(r) u^{t_k}_{nlkj}(r) - E^{t_k}_{nlkj}(r)$$

$$= \epsilon^{t_k}_{nlkj} u^{t_k}_{nlkj}(r). \quad (5)$$

To evaluate $U^{t_k}_{nlkj}(r)$ and $E^{t_k}_{nlkj}(r)$ we write the interaction $V(r_1, r_2)$ in terms of its Fourier transform. This allows us to separate the functional dependence of the two coordinates $r_1$ and $r_2$. 

3
Spin and isospin conservation implies that in the direct term only the scalar \((p=1)\) and the isospin \((p=2)\) channels of the interaction contribute. For these direct terms we find the expression:

\[
\left[U_{nkjk}(r)\right]_{(p)} = 4\sqrt{2\pi} \int dr' r'^2 V^p_{(r,r')} \left[U_k(r')\right]_{(p)},
\]

where we have defined

\[
V^p_{(r,r')} = \int dq q^2 j_L(qr) j_L(qr') V^{(0)}_p(q),
\]

with \(j_L(x)\) a spherical Bessel function and

\[
V^{(0)}_p(q) = \sqrt{\frac{2\pi}{\pi}} \int dr r^2 j_0(qr) V_p(r).
\]

Finally, the function \(U\) is:

\[
\left[U_k(r)\right]_{(p)} = \begin{cases} 
\rho(r), & p = 1 \\
2 t_k \left[\rho^p(r) - \rho^n(r)\right], & p = 2
\end{cases}
\]

with \(t_k = \frac{1}{2} (-\frac{1}{2})\) according to \(k\) being a proton (neutron).

In eq. (9) we have indicated with \(\rho\) the nucleon density:

\[
\rho(r) = \sum_{nljt} \frac{2j+1}{4\pi} \left(\frac{u_{nljt}(r)}{r}\right)^2,
\]

and with \(\rho^p\) and \(\rho^n\) the proton and neutron densities, defined as in eq. (11) without the sum on \(t\), such as \(\rho = \rho^p + \rho^n\).

All the channels of the force contribute to the exchange term in eq. (5), which are expressed as:

\[
\left[E_{nkjk}^{l_t}(r)\right]_{(p)} = \sqrt{\frac{2}{\pi}} \sum_{n_{l_i}j_i m_{l_i}} u_{n_{l_i}j_i}^{l_t}(r) \int dr' u_{n_{l_i}j_i}^{l_t}(r') u_{nkjk}^{l_t}(r') \sum_L \xi(l_k + l_i + L) (2j_i + 1) (2L + 1) I_p \left[E_{kiL}(r,r')\right]_{(p)},
\]

where we have introduced the function

\[
\xi(l) = \frac{1}{2} \left[1 + (-1)^l\right].
\]

The term \(I_p\) is obtained from the calculation of the isospin matrix elements and is given by:

\[
I_p = \begin{cases} 
\delta_{l_k, l_t}, & p = 1, 3, 5 \\
2\delta_{l_k, -l_t} + \delta_{l_k, l_t}, & p = 2, 4, 6
\end{cases}
\]
where we have indicated with \( \delta \) the Kronecker symbol. Finally, the function \( E \) includes the angular momentum coupling pieces. For the scalar and isospin terms we have the following expression:

\[
[E_{kiL}(r, r')]_{(p=1,2)} = \left( \frac{j_k}{2} \frac{j_i}{2} \frac{L}{2} - \frac{1}{2} \frac{1}{2} \frac{L}{0} \right) \mathcal{V}_L^p(r, r'),
\]

where we have made use of the Racah 3j symbol.

The contribution of the spin dependent terms is given by:

\[
[E_{kiL}(r, r')]_{(p=3,4)} = 2 \left[ \left( \frac{l_k}{0} \frac{l_i}{0} \frac{L}{0} \right) - \frac{1}{2} \left( \frac{j_k}{2} \frac{j_i}{2} \frac{L}{2} - \frac{1}{2} \frac{1}{2} \frac{L}{0} \right) \right] \mathcal{V}_L^p(r, r').
\]

Finally, for the tensor channels we have:

\[
[E_{kiL}(r, r')]_{(p=5,6)} = 2\sqrt{30} (2l_i + 1) (2l_k + 1) \sum_{L', J} (-i)^{L-L'} (-1)^J \mathcal{V}_{LL'}^p(r, r')
\]

\[
(2J + 1)(2L' + 1) \left\{ \frac{l_k}{L} \frac{j_k}{J} \frac{l_i}{l_i} \frac{j_i}{j_i} \frac{l}{l} \frac{j}{j} \right\} \left\{ \frac{l_k}{L} \frac{j_k}{j_k} \frac{l_i}{l_i} \frac{j_i}{j_i} \frac{l}{l} \frac{j}{j} \right\},
\]

where the Racah 6j and 9j symbols have been used and where we have introduced the function

\[
\mathcal{V}_{LL'}^p(r, r') = \int dq \, q^2 j_L(qr) j_L'(qr') V_p^{(2)}(q),
\]

with

\[
V_p^{(2)}(q) = -\sqrt{2} \int dr \, r^2 j_2(qr) V_p(r).
\]

The solution of eq. (13) provide us with the sp energies \( \epsilon \) and wave functions \( u(r) \). This solution has been obtained iteratively using the plane waves expansion method of refs. [10]. The center of mass motion has been considered in its simplest approximation, consisting in inserting the nucleon reduced mass in the Hamiltonian. The sp wave functions used to start the iterative procedure have been generated by a Saxon–Woods potential without spin-orbit and Coulomb terms. This means we have used the same starting wave functions for both protons and neutrons and for sp states which are spin–orbit partners.

The total energy of the system is calculated as:

\[
E = \sum_k \epsilon_k - \frac{1}{2} \sum_{k_i} \left[ \int d^3r_1 \, d^3r_2 \, \phi^*_k(r_1) \phi^*_j(r_2) V(|r_{12}|) \phi_k(r_1) \phi_j(r_2) \\
- \int d^3r_1 \, d^3r_2 \, \phi^*_k(r_1) \phi^*_j(r_2) V(|r_{12}|) \phi_j(r_1) \phi_k(r_2) \right]
\]

\[
= \sum_{nljt} (2j + 1) \epsilon^t_{nlj} - \frac{1}{2} \left[ 4\pi \int dr \, r^2 \rho(r) \left( \sum_{p=1}^6 [U^t_{nlj}(r)]_p \right) \\
- \sum_{nljt} (2j + 1) \int dr \, \left( \sum_{p=1}^6 [E^t_{nlj}(r)]_p \right) \right]
\]
3 Results and discussion

Our calculations are based on a finite range effective force widely used in HF calculations, the B1 interaction of Brink and Boeker [7] which was constructed to reproduce the experimental binding energies of $^4$He, $^{16}$O and $^{40}$Ca. With this interaction we have performed HF calculations also for $^{12}$C, $^{14}$C, $^{48}$Ca and $^{208}$Pb nuclei.

A comparison between the binding energies obtained in our calculations with the experimental values [11] is given in table 1. While the energies of $^4$He, $^{16}$O and $^{40}$Ca are rather well reproduced, the model fails in describing those of the other nuclei. A study of the contribution of the four components of the force shows that only the spin–isospin (p=4) term provides attraction. The contribution of the isospin (p=2) and spin (p=3) channels is the same for the $Z=N$ nuclei. Since in the present calculations protons and neutrons wave functions are identical, for $Z=N$ nuclei the proton and neutron densities are equal, therefore the direct isospin term, eq. (9), is zero and the two exchange terms for p=2 and p=3, give the same result. Of course this picture breaks down for nuclei with neutron excess like $^{14}$C, $^{48}$Ca and $^{208}$Pb.

To investigate the influence of the tensor component of the force on HF calculations we have added to the B1 interaction the tensor force obtained from the Argonne $v_{14}$ potential [8] and that obtained from the Jülich–Stony Brook (JSB) interaction [6]. The tensor terms of the JSB interaction are constructed by considering the exchange of the $\pi$ plus $\rho$ mesons, therefore they are active only in the tensor isospin channel. On the other hand, the pure tensor term of the Argonne potential is very small if compared with the tensor-isospin one. For this reason in our calculations we have used only the tensor-isospin terms of the two interactions. These terms are shown in the panel (a) of fig. 1.

This treatment of the tensor part of the interaction reproduces rather well the tensor terms of an effective interaction calculated within a Brueckner G-matrix approach. In ref. [12] is it shown that the effective force in the tensor channels is very similar to the bare nucleon–nucleon interaction. From fig. 1 the similarity between the JSB and Argonne tensor isospin channels is evident in the low momentum region.

We did not use the full Argonne and JSB interactions because they are not suited for HF calculations. The Argonne potential is a realistic nucleon–nucleon interaction which reproduces the experimental data of the two nucleon systems, and therefore it has a strong repulsive core. With this interaction we have calculated $^{16}$O and $^{40}$Ca and both of them are unbound (52.08 and 217.18 MeV respectively). The JSB interaction is an effective force designed to describe low–lying excited states within the Landau–Migdal theory of finite Fermi systems, and for HF calculation it turns out to be too attractive.

The binding energies obtained with the interactions constructed by adding to the B1 interaction the tensor terms of the Argonne $v_{14}$ potential (A) and that of the JSB interaction (JSB) are shown in table 2. A comparison with the results of table 1 shows that the contribution of the tensor force is very small.

The set of sp energies for the nuclei we have studied is shown in tables 3–7. For brevity we do not show these energies for the $^{208}$Pb case. One can notice that in the $^{16}$O and
For $^{40}$Ca nuclei, the sp energies of the spin–orbit partner levels are the same, while for $^{14}$C and $^{48}$Ca they are different.

This result can be understood analyzing eq. (16). If the $r$–dependent terms would be constant, the angular momentum sums for nuclei having spin–orbit partner states occupied would be exactly zero. In reality each term is identified by small variations produced by the integral on $q$, depending from $L$ and $L'$ and the integral on $r$ depending from the sp wave functions. These variations are not large enough to prevent big cancelations between the contribution of the spin–orbit partners terms. The contribution of the tensor interaction can be significant in nuclei where not all the sp spin–orbit partners levels are occupied. In closed shell nuclei there are at most two of such a levels, one for neutrons and one for protons. The contribution of the tensor channel should be compared with that of the other channels where all the sp states contribute. In light nuclei, like $^{12}$C, the tensor interaction could produce a noticeable contribution if compared with that generated by the other channels of the force which involves few sp levels. We expect that in heavier nuclei the tensor contribution produced by only one sp level should be compared with that produced by the other, many, sp levels for the central channels of the force. For this reason in the tables the effect of the tensor force is noticeable only for those nuclei having spin–orbit partners not fully occupied.

It is interesting to notice that the spin–orbit splitting produced by the tensor force goes in the opposite direction with respect to the experimental one. Clearly, a more realistic description of the nuclear ground state in terms of mean field model requires the presence of explicit spin–orbit terms in the interaction.

In order to test the sensitivity of the $^{12}$C ground state properties to the tensor interaction we have inserted a tensor–isospin channel of gaussian shape (in coordinate space) whose parameters have been fixed to reproduce the experimental binding energy of this nucleus. This new tensor force is shown in the panel (b) of fig. 1 and the results obtained with this new interaction for the other nuclei are shown in the tables by the columns labeled T6. It is worth to notice that this interaction has opposite sign with respect to the tensor terms of the JSB and Argonne interaction and a much stronger strength.

The comparison done in table 2 between the binding energies obtained with this new interaction with those previously obtained shows that only the results of the two carbon isotopes have been strongly modified. In this table we see that the binding energies of the nuclei with all spin–orbit partners levels occupied are very little modified by the tensor force. The $^{48}$Ca and $^{208}$Pb nuclei show more sensitivity to the modification of the tensor component of the force, but it is however rather small. The same kind of effects can be seen in the other tables showing the sp energies. The sp energies of $^{12}$C and $^{14}$C nuclei are strongly modified by the new tensor force, but those of $^{16}$O and $^{40}$Ca remain the same. In $^{48}$Ca the modification of the sp energies are relevant, even though the change on the binding energy is very small (∼2%).

In order to see how the modification of the tensor interaction can affect the sp wave functions we have calculated the nucleon distributions. As example of the results obtained we show in fig. 2 the proton distributions of the $^{12}$C, $^{14}$C, $^{40}$Ca and $^{48}$Ca nuclei. On the
scale of the figure the curves representing the Argonne and JSB results are overlapped to the curves of the B1 results. The figure shows that the JSB and Argonne tensor potentials do not produce sizeable effects on the proton distributions. The situation is quite different when the T6 tensor terms is used. The proton distribution of $^{12}$C and $^{14}$C are quite different, while the effect on $^{40}$Ca and $^{48}$Ca are negligible. These results confirm the previous analysis on the behaviour of the tensor interaction. The tensor force plays an important role in $^{12}$C and $^{14}$C, but its effects are essentially zero for nuclei with fully occupied spin–orbit partner levels, and very small for medium–heavy nuclei.

4 Conclusions

In this work we have studied the effects of the tensor interaction on HF calculations. We found that there are big cancelations between the contributions of sp levels which are spin–orbit partners. For this reason, only the contribution of those sp states not having occupied the spin orbit partner level is significant. A closed shell nucleus can have at most two of these states, one for protons and one for neutrons, and, as a consequence, the effect is relatively small in heavy nuclei where it has to be compared with the effect of the other terms of the force active on all the sp levels. The situation is different for $^{12}$C where only two levels are occupied, therefore, as we have shown, the effect of the tensor interaction is comparable with that of the other terms.

One may argue whether the difficulties in reproducing the $^{12}$C properties of traditional HF calculations can be overcome by inserting the tensor terms of the interaction. We have shown that, if these terms are included, it is possible to reproduce the $^{12}$C binding energies without spoiling the agreement obtained for the other nuclei. To obtain this results the use of tensor forces very different from those of Argonne and JSB interactions has been necessary. On the other hand, the study of excited low-lying magnetic states [K] gives strong indications that the effective tensor isospin interaction should be quite similar to those of the Argonne and JSB interactions. The unified description of ground and excited nuclear states within a Hartree-Fock plus Random Phase Approximation theoretical scheme, rules out the possibility of fixing the tensor part of the effective interaction with a fit to the $^{12}$C ground state properties.

The task of constructing a new finite–range interaction to be used in mean field calculations was beyond the aim of the present paper, and it will be pursued in the future, by adding finite range spin–orbit and density dependent terms. In any case the results we have presented show the need of including tensor terms in this effective interaction if one wants the model to be valid on the full isotope table.

Figure Captions

Figure 1: Tensor isospin terms added to the B1 interaction. In the panel (a) the curve labeled with A represents the term of the Argonne $v_{14}$ potential [8], that labeled as JSB the term of the Jülich–Stony Brook interaction of ref. [6]. The panel (b) shows the interaction adjusted to reproduce the $^{12}$C experimental binding energy.

Figure 2: Proton density distributions obtained with the B1 interaction (full lines) with the A interaction (dashed lines), with the JSB interaction (dotted–dashed lines) and with the T6 interaction (doubly dotted–dashed lines). On the scale of the figure the A and JSB results are overlapped.
