Abstract: We study the Yang–Mills measure on the sphere with unitary structure group. In the limit where the structure group has high dimension, we show that the traces of loop holonomies converge in probability to a deterministic limit, which is known as the master field on the sphere. The values of the master field on simple loops are expressed in terms of the solution of a variational problem. We show that, given its values on simple loops, the master field is characterized on all loops of finite length by a system of differential equations, known as the Makeenko–Migdal equations. We obtain a number of further properties of the master field. On specializing to families of simple loops, our results identify the high-dimensional limit, in non-commutative distribution, of the Brownian bridge in the group of unitary matrices starting and ending at the identity.

1. Introduction

The Yang–Mills measure, associated to a (two-dimensional) surface $\Sigma$ and to a compact Lie group $G$, is a probability measure on (generalized) connections of principal $G$-bundles over $\Sigma$. It was introduced in a series of works by Gross, King and Sengupta [29], Fine [21], Driver [17], Witten [52,53], Sengupta [48] and Lévy [38], as a mathematical version of Euclidean Yang–Mills field theory. See also [11] for recent progress in higher dimensions. In this paper, we will consider the Yang–Mills measure in the case where the surface $\Sigma$ is fixed and the group $G$ is a classical matrix group of high dimension.

The interest of such a set-up from the viewpoint of random matrix theory was first raised in the mathematics literature by Singer [50], who made several conjectures, based on earlier work in physics [26,27,34,35]. The high-dimensional limit of the Yang–Mills measure when $\Sigma$ is the whole plane has since been studied by Xu [54], Sengupta [49], Lévy [40], Anshelevich and Sengupta [1], Dahlqvist [13] and others [8,24].

We focus here on the case where the surface $\Sigma$ is a sphere. This case has received particular attention in the physics literature [6,14,28,47] as it displays a phase transition of third order named after Douglas and Kazakov [15]. A corresponding mathematical analysis of the partition function was achieved by Boutet de Monvel and Shcherbina [7] and Lévy and Maïda [43]. The main result of the present work, Theorem 2.2, confirms a conjecture of Singer [50], showing that, under the Yang–Mills measure on the sphere for the unitary group $U(N)$, the traces of loop holonomies converge as $N \to \infty$ to a deterministic limit. We characterize this limit analytically and derive some further properties. Following the physics literature, the limit is called the master field on the sphere.

As a by-product of our main result, we show that the Brownian loop in $U(N)$, that is to say, the Brownian bridge starting and ending at the identity, converges in non-commutative distribution as $N \to \infty$ to a certain non-commutative process, which we call the free unitary Brownian loop. The notion of free unitary Brownian motion was first defined by Biane [4], using free stochastic calculus, and moreover identified as a limit of the Brownian motion on $U(N)$. This latter limit was further studied in Lévy [39], Lévy and Maïda [42] and Collins, Dahlqvist and Kemp [12]. Our work may be considered as a first instance of the free unitary Brownian loop as a limit of a matrix valued process.
Defining it directly in the setting of free probability is an interesting open problem that cannot be handled so far by classical tools of free stochastic calculus, such as the ones introduced in \cite{4,5}.

There is a system of relations, discovered by Makeenko and Migdal \cite{45}, indexed by families of embedded loops, between the expectations under the Yang–Mills measure of polynomials in the traces of loop holonomies. These have now been proved for the whole plane by Lévy \cite{40} and Dahlqvist \cite{13} and for any compact surface by Driver, Gabriel, Hall and Kemp \cite{18}. They belong to the class of Schwinger–Dyson equations, a family of equations obtained by generalizing integration-by-parts formulas to the setting of functional integrals. See for example \cite{30} and \cite{9,10}, where these equations are proved and used in different models of random unitary matrices and for a lattice version of the Yang–Mills measure. For the Yang–Mills functional integral, this heuristic derivation has been justified recently by Driver \cite{16}. The Makeenko–Migdal equations provide a potential line of argument to prove convergence of the Yang–Mills measure as $N \to \infty$, which is to show a suitable concentration estimate for the holonomy traces, and to pass to the limit in the equations, showing that the limit equations determine a unique limit object. In the whole plane case, moment estimates for unitary Brownian motion provide the needed concentration, and the Makeenko–Migdal equations may be augmented by a further equation, such that the whole system of equations then characterizes the limit field. So the programme has been completed in that case \cite{13,40}. However, as noted in \cite{18}, the concentration and characterization problems have remained open in general.

In this paper, we will establish two key points. First, for simple loops, we show in Proposition 3.1 that expectations and covariances of the holonomy traces can be represented by functionals of a discrete $\beta$-ensemble. This representation allows us to identify the limit in probability of these traces as $N \to \infty$, following the work of Guionnet and Maïda \cite{30}, Johansson \cite{32} and Féral \cite{20} on discrete $\beta$-ensembles. This amounts to a rigorous version of ideas explained by Boulatov \cite{6} and Douglas and Kazakov \cite{15}. The second point, shown in Sect. 4 using the Makeenko–Migdal equations, is that the convergence of marginals to a deterministic limit for simple loops forces the same to hold for a more general class of loops. Then, by adapting some estimates of Lévy \cite{40}, we are able to consider eventually all loops of finite length, allowing us to express certain key properties of the master field in a natural way.

An alternative line of argument for the first point, which we shall discuss elsewhere, would be to use the fact that the process of eigenvalues of the marginals of the Brownian loop is known to have the same law as a Dyson Brownian motion on the circle, starting from 1 and conditioned to return to 1. Indeed, several scaling limits of this conditioned process have recently been understood by Liechty and Wang \cite{44}. This link was first observed in the physics literature by Forrester, Majumdar and Schehr \cite{22,23}. Section 3 gives another way to obtain macroscopic results on the empirical distribution of this process.

The paper is organized as follows. Section 2 introduces the model and our results. Section 3 shows convergence and concentration of holonomy traces for simple loops, using a duality relation with a discrete $\beta$-ensemble. Section 4 explains how the Makeenko–Migdal equations can be used to extend this convergence to a general class of regular loops. Then, in Sect. 5, we make a final extension to all loops of finite length. Section 6 presents some further properties of the master field, including a relation with the free Hermitian Brownian loop in the subcritical regime, and a formula for the evaluation of the master field on a large class of loops.

\footnote{This point has recently been shown independently also by Brian Hall \cite{31}.}
Subject to certain modifications, to be explained in a future work, the argument explained here applies to other series of compact groups and also with the projective plane in place of the sphere.

2. Setting and Statement of the Main Results

We review the notion of a Yang–Mills holonomy field over a compact Riemann surface. Then we discuss its relation, in the case of the sphere, to the Brownian loop in a Lie group. Next, we state our main results on convergence of Yang–Mills holonomy in $U(N)$ over the sphere to the master field, and on analytic characterization of the master field. The proof of these main results has three steps, which are outlined in Sect. 2.5. Then we discuss some consequences of our results, for the convergence of spectral measures of loop holonomies, and for the high-dimensional limit of the Brownian loop in $U(N)$. Finally, we discuss how the master field can be considered as a natural family of infinite-dimensional unitary transport operators, following up some suggestions of Singer [50].

2.1. Yang–Mills measure on a compact Riemann surface. We recall in this subsection the notion of Yang–Mills measure in two dimensions, following the formulation of Lévy [38], as a field of holonomies indexed by paths of finite length. Let $\Sigma$ be a closed two-dimensional Riemannian manifold and let $G$ be a compact Lie group. Fix an area measure on $\Sigma$ having a continuous positive density with respect to Lebesgue measure in each coordinate chart. Write $T$ for the total area of $\Sigma$ and denote by $1$ the unit element of $G$. Fix a bi-invariant Riemannian metric on $G$ and denote the associated heat kernel by $p = (p_t(g) : t \in (0, \infty), g \in G)$. Thus $p$ is the unique $C^\infty$ positive function on $(0, \infty) \times G$ such that

$$\frac{\partial p}{\partial t} = \frac{1}{2} \Delta p$$

and, for all continuous functions $f$ on $G$, in the limit $t \to 0$,

$$\int_G f(g)p_t(g)dg \to f(1).$$

Here we have written $\Delta$ for the Laplace–Beltrami operator and $dg$ for the normalized Haar measure on $G$.

We specialize in later sections to the case where $\Sigma$ is the Euclidean sphere $\mathbb{S}_T$ of total area $T$

$$\mathbb{S}_T = \{x \in \mathbb{R}^3 : 4\pi|x|^2 = T\}$$

and where $G$ is the group $U(N)$ of unitary $N \times N$ matrices. The Lie algebra of $U(N)$ is the space of skew-Hermitian matrices $\mathfrak{u}(N)$. We specify a metric on $U(N)$ by the following choice of inner product on $\mathfrak{u}(N)$

$$\langle g_1, g_2 \rangle = N\text{Tr}(g_1g_2^*)$$

where $\text{Tr}(g) = \sum_{i=1}^N g_{ii}$. This dependence of the metric on $N$, which is standard in random matrix theory, is chosen so that the objects of interest to us have a non-trivial scaling limit as $N \to \infty$. 

By an oriented path in $\Sigma$ we mean a continuous map $[0, 1] \to \Sigma$. Write $\text{Path}(\Sigma)$ for the set of oriented paths of finite length in $\Sigma$, parametrized by $[0, 1]$ at constant speed. Denote the length of a path $\gamma \in \text{Path}(\Sigma)$ by $\ell(\gamma)$. We consider $\text{Path}(\Sigma)$ as a metric space, with the length metric

$$d(\gamma, \gamma') = |\ell(\gamma) - \ell(\gamma')| + \inf_{\tau \in [0,1]} \sup_{t \in [0,1]} d(\gamma_\tau(t), \gamma'_\tau(t))$$

(2)

where the infimum is taken over homeomorphisms $\tau$ of $[0, 1]$. Each path $\gamma$ has a starting point $\gamma$ and a terminal point $\gamma$. Write $\gamma^{-1}$ for the reversal of $\gamma$, that is, the path of reverse orientation from $\gamma$ to $\gamma$. For paths $\gamma_1, \gamma_2$ such that $\gamma_1 = \gamma_2$, we write $\gamma_1 \gamma_2$ for the path obtained by their concatenation (and reparametrization by $[0, 1]$ at constant speed). Write $\text{Loop}(\Sigma)$ for the set of loops of finite length in $\Sigma$. Thus

$$\text{Loop}(\Sigma) = \{ \gamma \in \text{Path}(\Sigma) : \gamma = \gamma \}.$$ 

Write also $\text{Path}_{x, \gamma}(\Sigma_T)$ for the set of paths from $x$ to $\gamma$, and $\text{Loop}_{x, \gamma}(\Sigma_T)$ for the set of loops based at $x$. Given paths $\gamma, \gamma_0$, we say that $\gamma_0$ is a simple reduction of $\gamma$ if we can write $\gamma$ and $\gamma_0$ as concatenations

$$\gamma = \gamma_1 \gamma_2, \quad \gamma_0 = \gamma_1 \gamma_2$$

for some paths $\gamma_1, \gamma_2$. More generally, we say that $\gamma_0$ is a reduction of $\gamma$ if there is a sequence of paths $(\gamma_1, \ldots, \gamma_n)$ such that $\gamma_{i-1}$ is a simple reduction of $\gamma_i$ for all $i$ and $\gamma_n = \gamma$. Given paths $\gamma_1, \gamma_2$, we write $\gamma_1 \sim \gamma_2$ if there is a path $\gamma_0$ which is a reduction of both $\gamma_1$ and $\gamma_2$.

Given a subset $\Gamma$ of $\text{Path}(\Sigma)$ which is closed under reversal and concatenation, we call a function $h : \Gamma \to G$ multiplicative if

$$h_{\gamma^{-1}} = h^{-1}, \quad h_{\gamma_1 \gamma_2} = h_{\gamma_2} h_{\gamma_1}$$

for all $\gamma$ and for all $\gamma_1, \gamma_2$ with $\gamma_1 = \gamma_2$. We denote the set of such multiplicative functions by $\text{Mult}(\Gamma, G)$. Note that, for any such function $h$, we have $h_{\gamma_1} = h_{\gamma_2}$ whenever $\gamma_1 \sim \gamma_2$.

A path is simple if it is injective on $[0, 1]$, while a loop is simple if it is injective as a map on the circle. We say that a finite subset $\mathbb{G} = \{e_1, \ldots, e_m\} \subseteq \text{Path}(\Sigma)$ is an embedded graph in $\Sigma$ if each path $e_j$ is non-constant, is either simple or a simple loop, and meets other paths $e_k$ only at its endpoints. Then we refer to the sequence $(e_1, \ldots, e_m)$ as a labelled embedded graph. We will sometimes write abusively $\mathbb{G} = (V, E, F)$ to mean that $V$ is the set of endpoints of paths in $\mathbb{G}$, $E = \mathbb{G}$ and $F$ is the set of connected components of $\Sigma \setminus \{e^* : e \in \mathbb{G}\}$. Here

$$e^* = \{e(t) : t \in [0, 1]\}.$$ 

We say that an embedded graph $\mathbb{G}$ is a discretization of $\Sigma$ if each face $f \in F$ is a simply connected domain in $\Sigma$. Write $\text{Path}(\mathbb{G})$ for the subset of $\text{Path}(\Sigma)$ obtained by concatenations of the paths in $\mathbb{G}$ and their reversals.

A random process $H = (H_\gamma : \gamma \in \text{Path}(\Sigma))$ (on some probability space $(\Omega, F, \mathbb{P})$) taking values in $G$ is a Yang–Mills holonomy field if

(a) $H$ is multiplicative, that is, $H(\omega) \in \text{Mult}(\text{Path}(\Sigma), G)$ for all $\omega \in \Omega$,
(b) for any discretization $\mathbb{G} = (V, E, F)$ of $\Sigma$ and all $h \in \text{Mult}(\text{Path}(\mathbb{G}), G)$,

$$
\mathbb{P}(H_e \in dh_e \text{ for all } e \in E) = p_T(1)^{-1} \prod_{f \in F} p_{\text{area}(f)}(h_f) \prod_{e \in E} dh_e
$$

(3)

(c) for any convergent sequence $\gamma(n) \to \gamma$ in $\text{Path}(\Sigma)$ with fixed endpoints,

$$
H_{\gamma(n)} \to H_{\gamma} \quad \text{in probability.}
$$

(4)

The equation (3) specifies certain finite-dimensional distributions of $H$, considered as probability measures on $G^E$. The volume element $\prod_{e \in E} dh_e$ is the product of normalized Haar measures on $G$. For each face $f$, we have chosen a simple loop $\gamma(f) \in \text{Loop}(\mathbb{G})$ whose range is the boundary of $f$ and set $h_f = h_{\gamma(f)}$. The invariance properties of Haar measure and the heat kernel under inversion and conjugation guarantee that the expression (3) depends neither on the orientations of the edges nor on the choice of loops bounding the faces.

For each $\gamma \in \text{Path}(\Sigma)$, we can define a coordinate function $H_{\gamma} : \text{Mult}(\text{Path}(\Sigma), G) \to G$ by $H_{\gamma}(h) = h_{\gamma}$. We define a $\sigma$-algebra $\mathcal{C}$ on $\text{Mult}(\text{Path}(\Sigma), G)$ by

$$
\mathcal{C} = \sigma(H_{\gamma} : \gamma \in \text{Path}(\Sigma)).
$$

Then $(H_{\gamma} : \gamma \in \text{Path}(\Sigma))$ is a multiplicative random process on $(\text{Mult}(\text{Path}(\Sigma), G), \mathcal{C})$. We use the same notation $(H_{\gamma} : \gamma \in \text{Path}(\Sigma))$ both for this canonical coordinate process and also, more generally, for any multiplicative random process.

Our basic object of study is the Yang–Mills measure provided by the following theorem of Lévy [38, Theorem 2.62], building on earlier work of Driver [17] and Sengupta [48].

**Theorem 2.1.** There is a unique probability measure on $(\text{Mult}(\text{Path}(\Sigma), G), \mathcal{C})$ under which the coordinate process $(H_{\gamma} : \gamma \in \text{Path}(\Sigma))$ is a Yang–Mills holonomy field.

Let $H = (H_{\gamma} : \gamma \in \text{Path}(\Sigma))$ be a Yang–Mills holonomy field in $G$. We note the following properties of gauge invariance and invariance under area-preserving diffeomorphisms, which follow from invariance properties of (3) and the uniqueness statement of the theorem. Let $s : \Sigma \to G$ be any function and let $\psi : \Sigma \to \Sigma$ be an area-preserving diffeomorphism. Consider the processes

$$
H^s = (s(\gamma)H_{\gamma}s(\gamma)^{-1} : \gamma \in \text{Path}(\Sigma)), \quad H^\psi = (H_{\psi \circ \gamma} : \gamma \in \text{Path}(\Sigma)).
$$

Then $H^s$ and $H^\psi$ have the same law as $H$. In particular, the relevant data from $\Sigma$ are just its genus and the total area $T$ (Fig. 1).

### 2.2. Embedded Brownian loops

We specialize now to the case where the surface $\Sigma$ is the sphere $\mathbb{S}_T$ of area $T$. In each Yang–Mills holonomy field $H = (H_{\gamma} : \gamma \in \text{Path}(\mathbb{S}_T))$, there are many embedded Brownian loops in $G$ based at 1 and parametrized by $[0, T]$, as we now show. Recall that a random process $B = (B_t : t \in [0, T])$ taking values in $G$ is a Brownian loop based at 1 if

(a) $B$ is continuous, that is, $B(\omega) \in C([0, T], G)$ for all $\omega \in \Omega$, 

(b) $\mathbb{P}(\beta_e \in dh_e \text{ for all } e \in E) = p_T(1)^{-1} \prod_{f \in F} p_{\text{area}(f)}(h_f) \prod_{e \in E} dh_e$ 

(c) for any convergent sequence $\gamma(n) \to \gamma$ in $\text{Path}(\Sigma)$ with fixed endpoints, 

$$
H_{\gamma(n)} \to H_{\gamma} \quad \text{in probability.} 
$$

(4)
Yang–Mills Measure and the Master Field on the Sphere

![Image](https://via.placeholder.com/150.png?text=Fig. 1. A family of simple loops obtained by intersecting the sphere with a rotating plane, as described in Sect. 2.2)

(b) for all $n \in \mathbb{N}$, all $g_1, \ldots, g_{n-1} \in G$ and all increasing sequences $(t_1, \ldots, t_{n-1})$ in $(0, T)$, setting $g_0 = g_n = 1$ and $t_0 = 0$ and $t_n = T$ and writing $t_k = s_1 + \cdots + s_k$,

$$
P(B_{t_k} \in dg_k \text{ for } k = 1, \ldots, n-1) = p_T(1)^{-1} \prod_{i=1}^{n} p_{s_i}(g_i, g_{i-1}) \prod_{k=1}^{n-1} dg_k.
$$

Choose a point $x$ in $S_T$ and let $P$ be a tangent plane to $S_T$ at $x$, considered as embedded in $\mathbb{R}^3$. Choose a line $L$ in $P$ through $x$ and rotate $P$ once around $L$. The resulting intersections of $P$ with $S_T$, which are a nested family of circles, may be given a consistent orientation and then considered as a family in Loop($S_T$), all based at $x$. We can parametrize this family of loops as $(l(t) : t \in [0, T])$ so that the domain inside $l(t)$ has area $t$ for all $T$. Then, for all $n \in \mathbb{N}$ and all sequences $(t_1, \ldots, t_{n-1})$ in $(0, T)$, the loops $l(t_1), \ldots, l(t_{n-1})$ are the edges of a discretization of $S_T$. Define a random process $\beta = (\beta_t : t \in [0, T])$ in $G$ by

$$
\beta_t = H_{l(t)}.
$$

It is straightforward to deduce from property (b) of the Yang–Mills holonomy field that the finite-dimensional distributions of $\beta$ satisfy condition (b) for the Brownian loop. Hence, by standard arguments, $\beta$ has a continuous version, $B$ say, which is a Brownian loop in $G$ based at 1. The reader will see many ways to vary this construction while still obtaining a Brownian loop.

2.3. Convergence to the master field on the sphere. We specialize now to the case where the structure group $G$ is the group of $N \times N$ unitary matrices $U(N)$. Let $H^N = (H_N^\gamma : \gamma \in \text{Path}(S_T))$ be a Yang–Mills holonomy field in $U(N)$ over the sphere $S_T$ of area $T$. Our main results establish a law of large numbers for this random field in the limit $N \to \infty$, which we express for now in terms of the normalized trace

$$
\text{tr}_N(g) = \text{tr}(g) = N^{-1} \sum_{i=1}^{N} g_{ii}.
$$
Here is our first main result.

**Theorem 2.2.** There exists a function on loops

$$\Phi_T : \text{Loop}(S_T) \to \mathbb{C}$$

such that, for all \( l \in \text{Loop}(S_T) \),

$$\text{tr}_N(H_1^N) \to \Phi_T(l) \quad \text{in probability as } N \to \infty.$$

The function \( \Phi_T \) is known in the physics literature as the *master field on the sphere*. Until we have proved Theorem 2.2, it will be convenient provisionally to define \( \Phi_T \) by

$$\Phi_T(l) = \begin{cases} 
\lim_{N \to \infty} \mathbb{E}(\text{tr}_N(H_1^N)), & \text{if this limit exists,} \\
0, & \text{otherwise.}
\end{cases}$$

Note that, since \(|\text{tr}_N(H_1^N)| \leq 1\), by bounded convergence, as soon as we show that \( \text{tr}_N(H_1^N) \) converges in probability with deterministic limit, it will follow that \( \mathbb{E}(\text{tr}_N(H_1^N)) \) converges with the same limit, so that this limit must equal \( \Phi_T(l) \) as provisionally defined.

Given Theorem 2.2, the master field inherits certain properties from its finite-\( N \) approximations \( \mathbb{E}(\text{tr}_N(H_1^N)) \), as the reader may easily check.

**Proposition 2.3.** The master field \( \Phi_T \) has the following properties:

(a) \( \Phi_T = 1 \) on constant loops and \( \Phi_T(l) = \Phi_T(l^{-1}) \in [-1, 1] \) for all loops \( l \),

(b) \( \Phi_T(\gamma_1 \gamma_2) = \Phi_T(\gamma_2 \gamma_1) \) for all pairs of paths \( \gamma_1, \gamma_2 \) such that \( \gamma_1 \gamma_2 \) is a loop,

(c) \( \Phi_T(l_1) = \Phi_T(l_2) \) whenever \( l_1 \sim l_2 \),

(d) for all \( x, y \in S_T \), all \( n \in \mathbb{N} \), all \( a_1, \ldots, a_n \in \mathbb{C} \) and all \( \gamma_1, \ldots, \gamma_n \in \text{Path}_{x,y}(S_T) \),

$$\sum_{i,j=1}^{n} a_i a_j \Phi_T(\gamma_i \gamma_{j}^{-1}) \geq 0$$

(e) for all loops \( l \) and any area-preserving diffeomorphism \( \psi \) of \( S_T \),

$$\Phi_T(\psi(l)) = \Phi_T(l).$$

2.4. Characterization of the master field on the sphere. Our second main result is an analytic characterization of the master field. This will require some associated notions which we now introduce. Consider the following variational problem: minimize the functional

$$\mathcal{I}_T(\mu) = \int_{\mathbb{R}^2} \left\{ \frac{1}{2} (x^2 + y^2) T - 2 \log |x - y| \right\} \mu(dx) \mu(dy) \quad (5)$$

over the set of probability measures \( \mu \) on \( \mathbb{R} \) such that, for all intervals \([a, b] \),

$$\mu([a, b]) \leq b - a.$$
measure, with $0 \leq \rho_T(x) \leq 1$ for all $x$. In the case $T \in (0, \pi^2]$, $\rho_T$ is the semi-circle density of variance $1/T$, given by

$$\rho_T(x) = \frac{T}{2\pi} \sqrt{\frac{4}{T} - x^2}, \quad |x| \leq \frac{2}{\sqrt{T}}. \quad (6)$$

Note that the right-hand side in (6) exceeds 1 when $x = 0$ for $T > \pi^2$.

For $T \in (\pi^2, \infty)$, there is a unique $k \in (0, 1)$ such that

$$T = 8EK - 4(1 - k^2)K^2$$

where $K = K(k)$ and $E = E(k)$ are, respectively, the complete elliptic integrals of the first and second kind. See for example [37, Chapter 3, equations (3.1.3) and (3.5.4)].

Set

$$\alpha = 4kK/T, \quad \beta = 4K/T. \quad (7)$$

Then the minimizing density $\rho_T$ is identically 1 on $[-\alpha, \alpha]$, is supported on $[-\beta, \beta]$, and satisfies, for $|x| \in (\alpha, \beta)$,

$$\rho_T(x) = \frac{2\sqrt{(x^2 - \alpha^2)(\beta^2 - x^2)}}{\pi\beta|x|} \int_0^1 \frac{ds}{(1 - \alpha^2s^2/\beta^2)(1 - s^2)(1 - \alpha^2s^2/\beta^2)}. \quad (8)$$

See [43, Lemma 4.7, equation (4.14)]. See also [43, Figure 7] for an informative plot of the family of densities $(\rho_T : T \in (0, \infty))$.

Let us say that $l \in \text{Loop}(\mathbb{S}_T)$ is a regular loop if there is a labelled embedded graph $\mathbb{G}_l = (e_1, \ldots, e_m)$ in $\text{Path}(\mathbb{S}_T)$ such that $l$ is given by the concatenation $e_1 \ldots e_m$, in which $e_1$ has degree 2 and in which $e_2, \ldots, e_m$ have degree 4 and are transverse self-intersections of $l$. Here, we say that a self-intersection of $l$ at a vertex $v$ of degree 4 is transverse if, as $l$ passes through $v$, it arrives and leaves by opposite edges. Note that $\mathbb{G}_l$ is then uniquely determined by $l$.

Given a regular loop $l$ and a point $v$ of self-intersection of $l$, there are two regular loops $l_v$ and $\hat{l}_v$ starting from $v$, obtained by splitting $l$ at $v$, that is, by following $l$ on its first and second exit from $v$, respectively, until it first returns to $v$. Note that both $l_v$ and $\hat{l}_v$ have fewer self-intersections than $l$. See Fig. 2 for an example. Denote by $f_1$ the face of $\mathbb{G}$ which is adjacent to the two outgoing strands of $l$ at $v$, and denote by $f_1, f_2, f_3, f_4$ the faces of $\mathbb{G}$ found on making a small circuit around $v$ in the positive sense, starting from $f_1$. Note that these faces may not all be distinct. For each face $f$ of $\mathbb{G}$, define

$$\text{sgn}_v(f) = \sum_{k=1}^4 (-1)^{k+1}1_{\{f_k\}}(f).$$

In the case where the faces $f_1, f_2, f_3, f_4$ are distinct, we have $\text{sgn}_v(f_1) = \text{sgn}_v(f_3) = 1$ and $\text{sgn}_v(f_2) = \text{sgn}_v(f_4) = -1$. Since $\mathbb{G}$ is embedded in the sphere, the only other possibility is that $f_1 = f_3 \neq f_2 \neq f_4 \neq f_1$, in which case $\text{sgn}_v(f_1) = 2$ and $\text{sgn}_v(f_2) = \text{sgn}_v(f_4) = -1$. See Fig. 3. For $\eta > 0$, we say that a $C^\infty$ map

$$\theta : [0, \eta) \times \mathbb{S}_T \to \mathbb{S}_T$$

is a Makeenko–Migdal flow at $(l, v)$ if

(a) $\theta(0, x) = x$ for all $x$,}
Fig. 2. The splitting of the loop $e_1 e_2 \ldots e_7$ on the left-hand-side yields the two loops $e_2 e_3 e_4$ and $e_5 e_6 e_7 e_1$ respectively represented with plain and dashed strands.

Fig. 3. The value of $\text{sgn}_v$, where $v$ is denoted by a dot, is printed on each face of the embedded graph for two different loops.

\begin{align*}
\frac{d}{dt} \text{area}(\theta(t, f)) &= \text{sgn}_v(f). \tag{9}
\end{align*}

We can now state our analytic characterization of the master field.

**Theorem 2.4.** The master field $\Phi_T : \text{Loop}(S_T) \to \mathbb{C}$ has the following properties, which together characterize it uniquely:

(a) $\Phi_T$ is continuous with respect to the length metric on $\text{Loop}(S_T)$,
(b) $\Phi_T$ is invariant under reduction: for all pairs of loops $l_1, l_2$ with $l_1 \sim l_2$,
\[
\Phi_T(l_1) = \Phi_T(l_2)
\]
(c) $\Phi_T$ is invariant under area-preserving homeomorphisms: for all regular loops $l$ and any area-preserving homeomorphism $\xi$ of $\mathbb{S}_T$ such that $\xi(l) \in \text{Loop}(\mathbb{S}_T)$,

$$
\Phi_T(\xi(l)) = \Phi_T(l)
$$

(d) $\Phi_T$ satisfies the Makeenko–Migdal equations: for all regular loops $l$, all points $v$ of self-intersection of $l$, and any Makeenko–Migdal flow $\theta$ at $(l, v)$, $\Phi_T(\theta(t, l))$ is differentiable in $t$ at 0 with

$$
\frac{d}{dt} \bigg|_{t=0} \Phi_T(\theta(t, l)) = \Phi_T(l_v) \Phi_T(\hat{l}_v)
$$

(e) for all simple loops $l$ and all $n \in \mathbb{N}$,

$$
\Phi_T(l^n) = \frac{2}{n\pi} \int_0^\infty \cosh \{ (a_1 - a_2)nx/2 \} \sin\{ n\pi \rho_T(x) \} dx
$$

where $a_1$ and $a_2$ are the areas of the connected components of $\mathbb{S}_T \setminus l^*$. 

Note that the integrand in (11) vanishes whenever $\rho_T(x) = 0$ or $\rho_T(x) = 1$. In property (e), we have written $l^n$ for the $n$-fold concatenation of $l$ with itself. In fact, it suffices for uniqueness that property (e) hold in the case $n = 1$, as we show in Sect. 6.4.

### 2.5. Outline of the main argument

We now outline the main steps in our proof of Theorems 2.2 and 2.4. We build progressively an understanding of the limit, first for simple loops, then regular loops, and finally for all loops of finite length. First, we prove in Sect. 3.5 the following statement for simple loops. The argument uses harmonic analysis in $U(N)$ to express means and covariances of $\text{tr}_N(H^n_{l^*})$ in terms of a discrete $\beta$-ensemble, whose asymptotics as $N \to \infty$ we can compute. Write $\text{Loop}_0(\mathbb{S}_T)$ for the set of simple loops in $\text{Loop}(\mathbb{S}_T)$. Let $l \in \text{Loop}_0(\mathbb{S}_T)$ and recall that we write $l^*$ for the range of $l$. Then $\mathbb{S}_T \setminus l^*$ has two connected components. Write $a_1(l)$ for the area of the component on the left of $l$ and $a_2(l)$ for the area of the component on the right. Then $a_1(l), a_2(l) > 0$ and $a_1(l) + a_2(l) = T$. Set

$$
\phi_T(n, a_1, a_2) = \frac{2}{n\pi} \int_0^\infty \cosh \{ (a_1 - a_2)nx/2 \} \sin\{ n\pi \rho_T(x) \} dx.
$$

**Proposition 2.5.** For all $n \in \mathbb{N}$,

$$
\text{tr}_N(H^n_{l^*}) \to \Phi_T(l^n) = \phi_T(n, a_1(l), a_2(l))
$$

uniformly in $l \in \text{Loop}_0(\mathbb{S}_T)$ in $L^2(\mathbb{P})$ as $N \to \infty$.

The next step is the following proposition, which is proved in Sect. 4.5. The argument is based on the Makeenko–Migdal equations for Wilson loops, which will be discussed in Sect. 4.3. Write $\text{Loop}_n(\mathbb{S}_T)$ the set of regular loops having at most $n$ self-intersections.

In order to state the proposition, we will need to introduce certain quantities associated to a regular loop $l \in \text{Loop}_n(\mathbb{S}_T)$. There is a winding number function $n_l : \mathbb{S}_T \setminus l^* \to \mathbb{Z}$, which we fix uniquely by requiring its minimal value to be 0. The winding number is discussed in more detail in Sect. 4.4. The function $n_l$ is constant on the faces of the associated embedded graph, which are the connected components of $\mathbb{S}_T \setminus l^*$. The notion of continuity in area is defined at the end of Sect. 4.1.
Proposition 2.6. For all \( n \in \mathbb{N} \),
\[
\text{tr}_N(H_l^N) \to \Phi_T(l)
\]
uniformly in \( l \in \text{Loop}_n(S_T) \) in \( L^2(\mathbb{P}) \) as \( N \to \infty \). Moreover, the restriction of the master field \( \Phi_T \) to \( \text{Loop}_n(S_T) \) is the unique continuous function \( \text{Loop}_n(S_T) \to \mathbb{C} \) with the following properties: it is invariant under area-preserving homeomorphisms and uniformly continuous in area, it satisfies the Makeenko–Migdal equations (10), and satisfies, for some constant \( C_n < \infty \) and all loops \( l \in \text{Loop}_n(S_T) \),
\[
|\Phi_T(l) - \phi_T(n_*, a_0, a_*)| \leq C_n(T - a_{k_0} - a_{k_*})
\]
where \( n_* \) is the maximum of the winding number function \( n_l \), where \( k_0 \) and \( k_* \) are the indices of faces of minimal and maximal winding number, and where \( a_0 \) and \( a_* \) are determined by
\[
a_0 + a_* = T, \quad a_* n_* = \sum_{k=1}^p a_k n_k
\]
where \( a_k \) and \( n_k \), for \( k = 1, \ldots, p \), are respectively the area and the winding number of the face of index \( k \).

Finally, we extend to all loops of finite length in the following proposition, which combines the statements of Theorems 2.2 and 2.4. The proof is given in Sect. 5, using approximation by piecewise geodesics, and by adapting some general arguments of Lévy [40].

Proposition 2.7. For all \( l \in \text{Loop}(S_T) \),
\[
\text{tr}_N(H_l^N) \to \Phi_T(l)
\]
in probability as \( N \to \infty \). Moreover, the master field \( \Phi_T \) is the unique continuous function \( \text{Loop}(S_T) \to \mathbb{C} \) with the following properties: it is invariant under reduction, invariant under area-preserving homeomorphisms, satisfies the Makeenko–Migdal equations (10) on regular loops, and satisfies (11) for simple loops.

2.6. Convergence of spectral measures. Let \((H_N^\gamma : \gamma \in \text{Path}(S_T))\) be a Yang–Mills holonomy field in \( U(N) \). For \( l \in \text{Loop}(S_T) \), consider the empirical eigenvalue distribution on the unit circle \( \mathbb{U} \), given by
\[
\nu_T^N(l) = \frac{1}{N} \sum_{i=1}^N \delta_{\lambda_i}
\]
where \( \lambda_1, \ldots, \lambda_N \) are the eigenvalues of \( H_l^N \) enumerated with multiplicity. Write \( \mathcal{M}_1(\mathbb{U}) \) for the set of Borel probability measures on \( \mathbb{U} \).
Corollary 2.8. There is a function $\nu_T : \text{Loop}(\mathbb{S}_T) \to \mathcal{M}_1(\mathbb{U})$ such that, for all $l \in \text{Loop}(\mathbb{S}_T)$,

$$
\nu_T^N(l) \to \nu_T(l)
$$

weakly in probability on $\mathbb{U}$ as $N \to \infty$. Moreover, for all simple loops $l$ and all $n \in \mathbb{N}$,

$$
\int_{\mathbb{U}} \omega^n \nu_T(l)(d\omega) = \frac{2}{n\pi} \int_0^\infty \cosh \{ (a_1(l) - a_2(l))nx/2 \} \sin\{n\pi \rho_T(x)\} dx.
$$

Moreover, for $T \in (0, \pi^2)$, all simple loops $l$, and all bounded Borel functions $f$,

$$
\int_{\mathbb{U}} f(\omega)\nu_T(l)(d\omega) = \int_{-\pi}^{\pi} f(e^{i\theta})s_{a_1a_2/T}(\theta)d\theta
$$

(14)

where $s_t$ is the semi-circle density of variance $t$, given by

$$
s_t(x) = \frac{1}{2\pi t} \sqrt{4t - x^2}, \quad |x| \leq 2\sqrt{t}.
$$

(15)

Proof. By Theorem 2.2, for $l \in \text{Loop}(\mathbb{S}_T)$ and all $n \in \mathbb{N}$, we have

$$
\int_{\mathbb{U}} \omega^n \nu_T^N(l)(d\omega) = \text{tr}(H^n_{i1}) \to \Phi_T(l^n)
$$

in probability as $N \to \infty$. Since $\mathbb{U}$ is compact, by a standard tightness argument, it follows that there exists a probability measure $\nu_T(l)$ on $\mathbb{U}$ such that

$$
\int_{\mathbb{U}} \omega^n \nu_T(l)(d\omega) = \Phi_T(l^n)
$$

for all $n \in \mathbb{N}$ and such that $\nu_T^N(l) \to \nu_T(l)$ weakly in probability as $N \to \infty$. By Theorem 2.4, $\Phi_T(l^n)$ is given by (11) for all simple loops $l$. Finally, we will show in Sect. 3.4 that, for all $T \in (0, \pi^2)$ and all $n \in \mathbb{N}$,

$$
\Phi_T(l^n) = \int_{-\pi}^{\pi} e^{i\theta} s_{a_1a_2/T}(\theta)d\theta
$$

so (14) holds for polynomials, and so it holds in general. \qed

Thus, for $T \in (0, \pi^2)$ and for simple loops $l$, the limiting spectral measure $\nu_T(l)$ has a semi-circle density on $\mathbb{U}$, with

$$
\text{supp}(\nu_T(l)) = \{e^{i\theta} : |\theta| \leq 2\sqrt{a_1a_2/T}\}.
$$

The maximal support is then $\{e^{i\theta} : |\theta| \leq \sqrt{T}\}$, achieved when $a_1 = a_2 = T/2$. Note that, in the critical case $T = \pi^2$, the two endpoints of the maximal support meet at $\theta = \pm \pi$. 
2.7. Free unitary Brownian loop. As a corollary of Theorem 2.2, we show that the Brownian loop in $U(N)$ based at 1 of lifetime $T$ converges in non-commutative distribution as $N \to \infty$. Moreover, we identify the limiting empirical distribution of eigenvalues at each time $t \in [0, T]$.

Consider the free unital $*$-algebra $A_T$ of polynomials over $\mathbb{C}$ in the variables $(X_t : t \in [0, T])$ and their inverses. Each element $Q \in A_T$ is a finite linear combination over $\mathbb{C}$ of monomials of the form

$$X_{t_1}^{\varepsilon_1} \cdots X_{t_n}^{\varepsilon_n}$$

where $t_1, \ldots, t_n \in [0, T]$ and $\varepsilon_1, \ldots, \varepsilon_n \in \{-1, 1\}$. Thus each $Q \in A_T$ may be written as a non-commutative polynomial

$$Q = q(X_t, X_t^{-1} : t \in [0, T])$$

with coefficients in $\mathbb{C}$. The operation $*$ is the unique conjugate-linear, anti-multiplicative involution on $A_T$ such that

$$X_t^* = X_t^{-1}.$$

For each $N \in \mathbb{N}$, there exists a Brownian loop $B_N^T = (B_t^N : t \in [0, T])$ in $U(N)$ based at 1 of parameter $T$. Define a random non-negative unit trace on $A_T$ by setting

$$\tau_N(Q) = \text{tr}_N(q(B_t^N, (B_t^N)^{-1} : t \in [0, T])).$$

Theorem 2.9. There is a non-negative unit trace $\tau_\infty$ on $A_T$ such that, for all $Q \in A_T$,

$$\tau_N(Q) \to \tau_\infty(Q) \text{ in probability as } N \to \infty.$$

Proof. It will suffice to consider the case where $B_N^T$ is constructed from a Yang–Mills holonomy field $(H^N_\gamma : \gamma \in \text{Path}(\mathbb{S}_T))$ in $U(N)$, as in Sect. 2.2. Then, for some $x \in \mathbb{S}_T$ and some family of loops $l(t) \in \text{Loop}(\mathbb{S}_T)$ based at $x$, we have

$$B_t^N = H^N_{l(t)} \text{ almost surely, for all } t \in [0, T].$$

Consider first the case of a monomial $Q = X_{t_1}^{\varepsilon_1} \cdots X_{t_n}^{\varepsilon_n}$ with $\varepsilon_1, \ldots, \varepsilon_n \in \{-1, 1\}$ and set $l_Q = l(t_n)^{\varepsilon_n} \cdots l(t_1)^{\varepsilon_1}$. Then, by Theorem 2.2,

$$\tau_N(Q) = \text{tr}((B_t^N)^{\varepsilon_1} \cdots (B_t^N)^{\varepsilon_n}) = \text{tr}((H^N_{l(t_1)})^{\varepsilon_1} \cdots (H^N_{l(t_n)})^{\varepsilon_n}) = \text{tr}(H^N_{l_Q}) \to \Phi_T(l_Q)$$

in probability as $N \to \infty$. Define $\tau_\infty(Q) = \Phi_T(l_Q)$ for all monomials $Q$ and extend $\tau_\infty$ linearly to $A_T$. Then $\tau_N(Q) \to \tau_\infty(Q)$ in probability as $N \to \infty$, for all $Q \in A_T$, and $\tau_\infty$ inherits the property of being a non-negative unit trace from its random approximations $\tau_N$. \hfill \square

---

2 Recall that a linear map $\tau$ on a unital $*$-algebra $A$ is a \textit{non-negative unit trace} if, for all $x, y \in A$,

$$\tau(x^*x) \geq 0, \quad \tau(1) = 1, \quad \tau(xy) = \tau(yx).$$

The pair $(A, \tau)$ is then a \textit{non-commutative probability space}. 
Given a non-commutative random process \( x = (x_t : t \in [0, T]) \) in a non-commutative probability space \((\mathcal{A}, \tau)\), let us say that \( x \) is a free unitary Brownian loop if, for all \( n \), all \( t_1, \ldots, t_n \in [0, T] \) and all \( (y_{t_k}, Y_{t_k}) \in \{(x_{t_k}, X_{t_k}), (x_{t_k}^*, X_{t_k}^*)\} \),
\[
\tau(y_{t_1} \ldots y_{t_n}) = \tau_\infty(Y_{t_1} \ldots Y_{t_n}).
\]
In particular, the canonical process \( (X_t : t \in [0, T]) \) is a free unitary Brownian loop in \((\mathcal{A}_T, \tau_\infty)\). We shall see in Sect. 6 that, in the subcritical regime \( T \leq \pi^2 \), a free unitary Brownian loop \( x \) has the same marginal distributions as \( e^{ib} \), where \( b \) is a free Brownian loop with the same lifetime. Thus the spectral measure of each marginal of a free unitary Brownian loop is the push-forward of a Wigner law by the exponential mapping to the circle. However, we shall also see that the full non-commutative distributions of \( x \) and \( e^{ib} \) are different.

2.8. The master field as a holonomy in \( U(\infty) \). We will carry out the suggestion of Singer [50], to use a variation of the Gelfand-Naimark-Segal construction to obtain from the master field a family of Hilbert spaces, indexed by \( \mathbb{S}_T \), and equipped with a canonical connection, viewed as a family of unitary transport operators indexed by \( \text{Path}(\mathbb{S}_T) \). First, in order to clarify and motivate this construction, we will make an analogous construction for finite \( N \), showing its relation to the notion of Yang–Mills holonomy field in \( U(N) \). Conditional on a certain non-degeneracy property for the master field, we will further exhibit the finite-\( N \) holonomy measures as recoverable by restriction of the limit holonomy field to certain invariant random subspaces.

We have presented the Yang–Mills holonomy field as a process \( (H^N_\gamma : \gamma \in \text{Path}(\mathbb{S}_T)) \) with values in \( U(N) \). However, the property of gauge-invariance allows us to think of it as follows. Suppose we are given a family of complex vector spaces \( V = (V_x : x \in \mathbb{S}_T) \), each equipped with a Hermitian inner product and having dimension \( N \). Choose, for each \( x \in \mathbb{S}_T \), a complex linear isometry \( s(x) : \mathbb{C}^N \to V_x \). Given a Yang–Mills holonomy field \( (H^N_\gamma : \gamma \in \text{Path}(\mathbb{S}_T)) \) in \( U(N) \), for each \( \gamma \in \text{Path}_{\text{subcrit}}(\mathbb{S}_T) \), we can define a complex linear isometry \( T_\gamma : V_x \to V_y \) by
\[
T_\gamma = s(y)H^N_\gamma s(x)^{-1}.
\]
Then, by gauge invariance, the law of the process \( (T_\gamma : \gamma \in \text{Path}(\mathbb{S}_T)) \) does not depend on the choice of the family of isometries \( (s(x) : x \in \mathbb{S}_T) \). We call any process with this law a Yang–Mills holonomy field in \( \text{Isom}(V) \). The original holonomy field \( (H^N_\gamma : \gamma \in \text{Path}(\mathbb{S}_T)) \) then corresponds to the case where \( V_x = \mathbb{C}^N \) for all \( x \). Moreover, given any Yang–Mills holonomy field \( (T_\gamma : \gamma \in \text{Path}(\mathbb{S}_T)) \) in \( \text{Isom}(V) \) and any choice of a family of complex linear isometries \( s(x) : \mathbb{C}^N \to V_x \), we obtain a Yang–Mills holonomy field \( (H^N_\gamma : \gamma \in \text{Path}(\mathbb{S}_T)) \) in \( U(N) \) by setting
\[
H^N_\gamma = s(y)^{-1}T_\gamma s(x).
\]

**Proposition 2.10.** Let \( (H^N_\gamma : \gamma \in \text{Path}(\mathbb{S}_T)) \) be a Yang–Mills holonomy field in \( U(N) \) and let \( E \) be an independent uniformly random unit vector in \( \mathbb{C}^N \). Define, for \( l \in \text{Loop}(\mathbb{S}_T) \),
\[
\tau^N_T(l) = \langle E, H^N_l E \rangle.
\]
Then \( \tau^N_T(l) \to \Phi_T(l) \) in probability as \( N \to \infty \) for all \( l \).
We already know that
\[ \mathbb{E}(\tau_N^T(l)|H_N^T) = \Phi_N^T(l) \rightarrow \Phi_T(l) \]
in probability as \( N \rightarrow \infty \). The proposition thus shows that the same convergence in probability holds without taking the expectation over the random vector \( E \). The extra randomness present in \( \tau_N^T \) makes it a more natural object than \( \Phi_N^T \) in certain constructions below.

**Proof.** Let \( Z_1, \ldots, Z_N \) be independent complex Gaussian random variables. Set
\[ S_N = \sum_{k=1}^N |Z_k|^2, \quad \tilde{E} = (Z_1, \ldots, Z_N)/\sqrt{S_N}. \]
Then \( \tilde{E} \) is a uniform random unit vector in \( \mathbb{C}^N \). Define, for \( l \in \text{Loop}(\mathbb{S}_T) \),
\[ \tilde{\tau}_N^T(l) = \sum_{k=1}^N \lambda_k \tilde{E}_k^2 = \sum_{k=1}^N \lambda_k |Z_k|^2 / S_N \]
where \( \lambda_1, \ldots, \lambda_N \) is an enumeration of the eigenvalues of \( H_N^T \). Since \( H_N^T \) is diagonalized by unitary conjugation and \( \tilde{E} \) is independent of \( H_N^T \), it follows that \( \tilde{\tau}_N^T(l) \) has the same distribution as \( \tau_N^T(l) \). By Corollary 2.8, the empirical distribution of eigenvalues
\[ \nu_N^T(l) = \frac{1}{N} \sum_{k=1}^N \delta_{\lambda_k} \]
converges weakly in probability on the unit circle \( \mathbb{U} \) with deterministic limit \( \nu_T(l) \) satisfying
\[ \Phi_T(l) = \int_{\mathbb{U}} \lambda \nu_T(l)(d\lambda). \]
But \( \mathbb{E}(|Z_k|^2) = 2 \), so we obtain the following limits in \( L^2 \)
\[ \frac{1}{N} \sum_{k=1}^N \lambda_k |Z_k|^2 \rightarrow 2\Phi_T(l), \quad S_N/N \rightarrow 2. \]
Hence \( \tilde{\tau}_N^T(l) \rightarrow \Phi_T(l) \) in probability as \( N \rightarrow \infty \). □

Fix a reference point \( r \in \mathbb{S}_T \) and consider for each \( x \in \mathbb{S}_T \) the vector space \( \mathcal{V}_x \) of complex functions on \( \text{Path}_{r,x}(\mathbb{S}_T) \) of finite support. Thus, each \( v \in \mathcal{V}_x \) has the form
\[ v = \sum_{i=1}^n a_i \delta_{\gamma_i} \]
for some \( n \geq 0 \), with \( a_i \in \mathbb{C} \) and \( \gamma_i \in \text{Path}_{r,x}(\mathbb{S}_T) \) for all \( i \). There are unique Hermitian forms \( \langle \cdot, \cdot \rangle_N^x \) and \( \langle \cdot, \cdot \rangle_x \) on \( \mathcal{V}_x \) such that, for all \( \gamma_1, \gamma_2 \in \text{Path}_{r,x}(\mathbb{S}_T) \),
\[ \langle \delta_{\gamma_1}, \delta_{\gamma_2} \rangle_N^x = \tau_N^T(\gamma_1 \gamma_2^{-1}), \quad \langle \delta_{\gamma_1}, \delta_{\gamma_2} \rangle_x = \Phi_T(\gamma_1 \gamma_2^{-1}). \]
By Proposition 2.10, \( (v, v')_N^x \rightarrow (v, v')_x \) in probability for all \( v, v' \). The form \( \langle \cdot, \cdot \rangle_N^x \) is non-negative definite for all \( N \), so \( \langle \cdot, \cdot \rangle_x \) is also non-negative definite, as we observed in Proposition 2.3. For \( x, y \in S_T \) and \( \gamma \in \text{Path}_{x,y}(S_T) \), there is a unique complex linear map \( T_{\gamma} : \mathcal{V}_x \rightarrow \mathcal{V}_y \) such that, for all \( \gamma_0 \in \text{Path}_{r,x}(S_T) \),

\[
T_{\gamma_0} = \delta_{\gamma_0}.\]

Note that, for \( \gamma_1, \gamma_2 \in \text{Path}_{r,x}(S_T) \),

\[
\langle T_{\gamma_1} T_{\gamma_2} \rangle_{\gamma} = \langle \delta_{\gamma_1} \delta_{\gamma_2} \rangle_{\gamma} = \tau_N(\gamma_1 \gamma_1^{-1} \gamma_2^{-1}) = \tau_N(\gamma_1 \gamma_2^{-1}) = \langle \delta_{\gamma_1} \delta_{\gamma_2} \rangle_{N}^x.
\]

It follows that \( \langle T_{\gamma} v_1, T_{\gamma} v_2 \rangle^N_x = \langle v_1, v_2 \rangle^N_x \) for all \( v_1, v_2 \in \mathcal{V}_x \). Similarly, \( T_{\gamma} \) preserves the form \( \langle \cdot, \cdot \rangle \).

For each \( x \in S_T \), write \( \mathcal{V}^N_x \) for the quotient of the vector space \( \mathcal{V}_x \) by the kernel

\[
\mathcal{K}^N_x = \{ v \in \mathcal{V}_x : \langle v, v \rangle^N_x = 0 \}.
\]

Write \( [v]^N = v + \mathcal{K}^N_x \). It is straightforward to check that, for \( \gamma_1, \gamma_2 \in \text{Path}_{r,x}(S_T) \) with \( \gamma_1 \sim \gamma_2 \), we have \( [\delta_{\gamma_1}]^N = [\delta_{\gamma_2}]^N \) in \( \mathcal{V}^N_x \).

**Proposition 2.11.** Almost surely, for all \( x \in S_T \), the random vector space \( \mathcal{V}^N_x \) has finite dimension \( N \).

**Proof.** Since \( T_N^x \) is a linear isometry for all paths \( \gamma \in \text{Path}(S_T) \), it will suffice to consider the case \( x = r \). Let \( (l(t) : t \in [0, T]) \) be a family of loops in \( \text{Loop}_x(S_T) \) such as considered in Sect. 2.2, now with \( x = r \). For \( k = 1, \ldots, N \) set \( l_k = l((k - 1)T/N) \).

Write \( \Omega_0 \) for the event that the random vectors \( H_{l_1} E = E, H_{l_2} E, \ldots, H_{l_N} E \) are linearly independent in \( \mathbb{C}^N \). The joint law of \( H_{l_2}, \ldots, H_{l_N} \) has a density \( \rho \) with respect to the product of normalized Haar measures on \( U(N)^{N-1} \) given by

\[
\rho(h_2, \ldots, h_N) = \frac{p_{T/N}(h_2)p_{T/N}(h_N)}{p_{T}(1)} \prod_{k=3}^{N} p_{T/N}(h_kh_{k-1}^{-1}).
\]

Consider the equivalent probability measure \( \tilde{P} \) given by

\[
d\tilde{P}/dP = \rho(H_{l_2}, \ldots, H_{l_N})^{-1}.
\]

Under \( \tilde{P} \), the random vectors \( H_{l_2} E, \ldots, H_{l_N} E \) are independent and uniformly distributed on the unit ball in \( \mathbb{C}^N \). Hence

\[
\tilde{P}(\Omega_0) = \tilde{P}(\Omega_0) = 1.
\]

Now, for

\[
v = \sum_{k=1}^{N} a_k \delta_{l_k}
\]

we have

\[
\langle v, v \rangle^N_r = \left| \sum_{k=1}^{N} a_k H_{l_k} E \right|^2.
\]
So, on the event \( \Omega_0, v \in \mathcal{K}_N \) only if \( a_1 = \cdots = a_N = 0 \), that is to say, \( l_1 + \mathcal{K}_N, \ldots, l_N + \mathcal{K}_N \) are linearly independent in \( V_x^N \). On the other hand, for any loop \( l \in \text{Loop}_r(S_T) \), on the same event \( \Omega_0, H_lE \) is a linear combination of \( H_{l_1}E, \ldots, H_{l_N}E \), so \( \delta_l + \mathcal{K}_N \) lies in the linear span of \( \delta_1 + \mathcal{K}_r, \ldots, \delta_N + \mathcal{K}_r \). \( \square \)

The form \((.,.)^N_x\) induces a random Hermitian inner product on \( V_x^N \), which we will denote also by \((.,.)^N_x\). Moreover, for all \( x, y \in S_T \) and all \( \gamma \in \text{Path}_{x,y}(S_T) \), we can define a random linear isometry \( T^N_y : V_x^N \rightarrow V_x^N \) by

\[
T^N_y (v + \mathcal{K}_x) = T_y v + \mathcal{K}_y.
\]

The family of isometries \( \{ T^N_y : \gamma \in \text{Path}(S_T) \} \) inherits the following properties from \( \{ T^N_y : \gamma \in \text{Path}(S_T) \} \):

\[
T^N_x = 1_x, \quad T^N_{\gamma_1 \gamma_2} = T^N_{\gamma_2} T^N_{\gamma_1}.
\]

Here, we have written \( x \) for the constant loop at \( x \), \( 1_x \) for the identity map on \( V_x \), and the second identity is valid whenever the concatenation \( \gamma_1 \gamma_2 \) is possible. On the other hand, if \( \gamma_1 \sim \gamma_2 \) then \( T^N_{\gamma_1} = T^N_{\gamma_2} \). Hence, since \( \gamma \gamma^{-1} \sim x \), we have

\[
T^{-N}_{\gamma^{-1}} T^N_x = T^N_{\gamma^{-1}} = T^N_{x^{-1}} = 1_x.
\]

In fact, the family of isometries \( \{ T^N_y : \gamma \in \text{Path}(S_T) \} \) may be considered as a Yang–Mills holonomy field in \( \text{Isom}(V^N) \), in a sense made precise in the following proposition.

**Proposition 2.12.** Conditional on \( (V^N_x : x \in S_T) \), choose a family of independent uniform random isometries \( (s(x) : x \in S_T) \) with \( s(x) : \mathbb{C}^N \rightarrow V_x^N \) for all \( x \), and set

\[
\tilde{H}^N_y = s(y)^{-1} T^N_y s(x).
\]

Then \( \{ \tilde{H}^N_y : \gamma \in \text{Path}(S_T) \} \) is a Yang–Mills holonomy field in \( U(N) \).

**Proof.** Consider, for each \( x \in S_T \), the unique linear map \( \pi^N_x : V_x \rightarrow \mathbb{C}^N \) such that \( \pi^N_x(\delta_y) = H^N_y E \) for all \( \gamma \in \text{Path}_{x,y}(S_T) \). Then \( \pi_N \) has kernel \( \mathcal{K}_N \) and the quotient map \( V_x^N \rightarrow \mathbb{C}^N \), which we denote abusively also by \( \pi_N \), is an isometry, by definition of \( (.,.)^N_x \). For \( \gamma_0 \in \text{Path}_{x,y}(S_T) \) and \( \gamma \in \text{Path}_{x,y}(S_T) \), we have

\[
\pi^N_y(T^N_y \delta_{\gamma_0}) = \pi^N_y(\delta_{\gamma_0}) = H^N_{\gamma_0} E = H^N_y H^N_{\gamma_0} E = H^N_y \pi^N_x(\delta_{\gamma_0})
\]

so the quotient maps satisfy, for all \( v \in V_x^N \),

\[
\pi^N_y(T^N_y v) = H^N_y \pi^N_x(v).
\]

Since Haar measure is invariant under multiplication, the random variables \( \{ \pi^N_N s(x) : x \in S_T \} \) in \( U(N) \) are independent, uniformly distributed, and independent of \( H^N_y \). Now

\[
\tilde{H}^N_y = (\pi^N_y s(y))^{-1} H^N_y (\pi^N_x s(x))
\]

so \( \{ \tilde{H}^N_y : \gamma \in \text{Path}(S_T) \} \) is a Yang–Mills holonomy field in \( U(N) \) by gauge invariance. \( \square \)
For each \( x \in S_T \), given a path \( \gamma \in \text{Path}_{r,x}(S_T) \), we can define a state \( \tau^N_\gamma \) on the set of bounded linear operators on \( V^N_x \) by

\[
\tau^N_\gamma (A) = ([\delta_\gamma]_N, A[\delta_\gamma]_N)_x^N.
\]

Then, for all \( l \in \text{Loop}_x(S_T) \),

\[
\tau^N_\gamma (T^N_l) = \langle \delta_\gamma, T_l[\delta_\gamma]_x^N \rangle = \langle \delta_\gamma, \delta_\gamma l \rangle_x^N = \tau^N_\gamma (\gamma l^{-1} l^{-1}) = \tau^N_\gamma (l).
\]

Then, on restricting \( \tau^N_\gamma \) to the von Neumann algebra \( A^N_x \) generated by \( (T^N_l : l \in \text{Loop}_x(S_T)) \), we obtain a non-negative unit trace \( \tau^N_x \) on \( A^N_x \), which does not depend on the choice of path \( \gamma \). This construction has been done starting from the random Hermitian forms \( \langle ., . \rangle_x^N \) for \( x \in S_T \). We now explore the analogous construction starting from \( \langle ., . \rangle_x \).

Consider the kernel

\[
K_x = \{ v \in V_x : \langle v, v \rangle_x = 0 \}
\]

and write \( V_x \) for the Hilbert space obtained by completing \( V_x/K_x \) with respect to \( \langle ., . \rangle_x \). Write \( [v] = v + K_x \). Then \( [\delta_\gamma]_1 = [\delta_\gamma]_2 \) whenever \( \gamma_1 \sim \gamma_2 \). For \( x, \gamma \in S_T \) and \( y \in \text{Path}_{x,\gamma}(S_T) \), there is a unique Hilbert space isometry \( T_\gamma : V_x \to V_y \) such that, for all \( v \in V_x \),

\[
T_\gamma (v + K_x) = T_\gamma v + K_y.
\]

The family of isometries \( (T_\gamma : \gamma \in \text{Path}(S_T)) \) then has the following properties:

\[
T_x = 1_x, \quad T_\gamma^{-1} = (T_\gamma)^{-1}, \quad T_{\gamma_1 \gamma_2} = T_{\gamma_2} T_{\gamma_1}
\]

where the last identity holds whenever the concatenation \( \gamma_1 \gamma_2 \) is possible.

For each \( x \in S_T \), given a path \( \gamma \in \text{Path}_{r,x}(S_T) \), we can define a state \( \tau_\gamma \) on the set of bounded linear operators on \( V_x \) by

\[
\tau_\gamma (A) = ([\delta_\gamma], A[\delta_\gamma])_x.
\]

Then, for all \( l \in \text{Loop}_x(S_T) \),

\[
\tau_\gamma (T_l) = \langle \delta_\gamma, T_l[\delta_\gamma]_x \rangle = \langle \delta_\gamma, \delta_\gamma l \rangle_x = \Phi_T (\gamma l^{-1} l^{-1}) = \Phi_T (l).
\]

Recall from Proposition 2.3 that \( \Phi_T (x) = 1 \) and \( \Phi_T (l_1 l_2) = \Phi_T (l_2 l_1) \). Then, on restricting \( \tau_\gamma \) to the von Neumann algebra \( A_x \) generated by \( (T_l : l \in \text{Loop}_x(S_T)) \), we obtain a non-negative unit trace \( \tau_x \) on \( A_x \), which does not depend on the choice of path \( \gamma \).

We note some further properties of \( (A_x, \tau_x) \). First, for all integers \( n \), and all \( l \in \text{Loop}_x(S_T) \),

\[
\tau_x (T^n_l) = \Phi_T (l^n) = \int_U \omega^n v_T (l)(d \omega)
\]

where \( v_T (l) \) is the limit spectral measure obtained in Sect. 2.6. So \( v_T (l) \) is the spectral measure of \( T_l \). (Here \( T \) refers to the area of the sphere, while \( T^n_l \) is the \( n \)th power of the transport operator \( T_l \) defined above.) Second, since the master field is invariant under
area-preserving diffeomorphisms of $S_T$, the choice of such a diffeomorphism $\psi$ gives an isomorphism $(A_x, \tau_x) \rightarrow (A_y, \tau_y)$ whenever $\psi(x) = y$.

Singer [50] conjectured, without explicit construction, that the von Neumann algebras $A_x$ were factors, that is to say, their centres were trivial. We remark that, if this conjecture holds then, since the spectral measures $\nu_T(l)$ are absolutely continuous, at least for simple loops separating the sphere into components of equal area, as follows from Proposition 6.2, and since $\tau_x$ is a finite normalized trace, we see that

$$\{\tau_x(p) : p \in A_x, p^2 = p\} = [0, 1]$$

and $A_x$ must be of type II$_1$ and have unique state $\tau_x$.

It is an open question whether in fact $K_x$ is spanned, for all $x$, by vectors of the form $\delta_\gamma - \delta_{\gamma_0}$, where $\gamma, \gamma_0 \in \text{Path}_{r,x}(S_T)$ and, for some sequence $(\gamma_n : n \in \mathbb{N})$ in $\text{Path}_{r,x}(S_T)$ with $\gamma_n \sim \gamma_0$ for all $n$, we have $\gamma_n \rightarrow \gamma$ in length. Since we know that such vectors all lie in $K_N$ for all $N$, if true, this would allow to identify $V_N^x$ with the orthogonal complement of $K_N^x/K_x$ in $V_x$. Then the Yang–Mills holonomy field $(T^N_\gamma : \gamma \in \text{Path}(S_T))$ in $\text{Isom}(V^N)$ would be obtained by restricting the family of isometries $(\tilde{T}_\gamma : \gamma \in \text{Path}(S_T))$ to the $N$-dimensional random subspaces $(V_N^x : x \in S_T)$.

3. Harmonic Analysis in $U(N)$ and a Discrete $\beta$-ensemble

3.1. A representation formula. Let $H = (H_\gamma : \gamma \in \text{Path}(S_T))$ be a Yang–Mills holonomy field in $U(N)$. Here, and from now on, we suppress mention of $N$ in the notation for $H$. On the other hand, for $l \in \text{Loop}(S_T)$ and $n \in \mathbb{Z}$, we will write $H^nl$ for the $n$th power of the matrix $H_l$ which, by the multiplicative property, is also given by $H_I^l$. We obtain in this subsection a key formula for the moments of the holonomy $H_l$ of a simple loop $l$ in terms of a certain discrete $\beta$-ensemble, with $\beta = 2$. Set

$$Z_{\text{sym}} = \begin{cases} \mathbb{Z}, & \text{if } N \text{ is odd,} \\ \mathbb{Z} + 1/2, & \text{if } N \text{ is even.} \end{cases}$$

Consider the discrete $\beta$-ensemble $\Lambda$ in $N^{-1}Z_{\text{sym}}$ given by

$$\mathbb{P}(\Lambda = \lambda) \propto \prod_{j,k=1}^{N} (\lambda_j - \lambda_k)^2 \prod_{i=1}^{N} e^{-N\lambda_i^2 T/2}$$

(16)

where $\lambda$ runs over decreasing sequences $(\lambda_1, \ldots, \lambda_N)$ in $N^{-1}Z_{\text{sym}}$. For $\alpha \in \mathbb{R}\{0\}$ and for $z \in \mathbb{C}$ with $|\alpha||z - \lambda_j| > 1$ for all $j$, set

$$G^\alpha_\lambda(z) = \frac{\alpha}{N} \sum_{j=1}^{N} \text{Log} \left( 1 + \frac{1}{\alpha(z - \lambda_j)} \right)$$

$^3$ See for example [51].
$^4$ See for example, Section 8.4 of [33].
where \( \text{Log} \) denotes the principal value of the logarithm. Then, for \( a \in (0, T) \), set \( I_0^a(\lambda) = 1 \) and define for \( n \in \mathbb{Z} \setminus \{0\} \)

\[
I_n^a(\lambda) = e^{-an^2/(2N)} \int_\gamma \exp\{-n(az - G_{\lambda}^{N/n}(z))\}dz
\]

where \( \gamma \) is any positively oriented simple loop around the set \([\lambda_N, \lambda_1]+\{z \in \mathbb{C} : |z| \leq |n|/N\}\). It is straightforward to check that \( I_n^a(\lambda) \) does not depend on the choice of \( \gamma \).

**Proposition 3.1.** Let \( l \in \text{Loop}(S_T) \) be a simple loop which divides \( S_T \) into components of areas \( a \) and \( b \). Then, for all \( m, n \in \mathbb{Z} \),

\[
\mathbb{E}(\text{tr}(H_l^{-m})\text{tr}(H_l^n)) = \mathbb{E}(I_m^a(\Lambda)I_n^b(\Lambda)).
\]

Here and from now on, we suppress the \( N \) in our notation for the normalized trace on \( U(N) \). This formula allows to prove the convergence of the random variables \( \text{tr}(H_l^n) \) for simple loops \( l \), as will be explained in Sect. 3.2.

To prove Proposition 3.1, we will use the decomposition of the heat kernel as a sum over the characters of \( U(N) \). The results we use may be found for example in [36]. For \( \lambda \in (\mathbb{Z}_{\text{sym}})^N \), set

\[
\|\lambda\|^2 = \frac{1}{N} \sum_{j=1}^N \lambda_j^2.
\]

Write \( \rho = (\rho_1, \ldots, \rho_N) \) for the unique minimizer of \( \|\cdot\| \) among decreasing sequences in \((\mathbb{Z}_{\text{sym}})^N\), which is given by

\[
\rho_j = \frac{1}{2}(N+1) - j.
\]

For \( \lambda \in \mathbb{Z}^N \), there is a unique continuous function \( \chi_\lambda : U(N) \to \mathbb{C} \) given by the Weyl character formula

\[
\chi_\lambda(g) = \det(e^{i\theta_j \rho_k})_{j,k=1}^N = \det(e^{i\theta_j(\lambda_k+\rho_k)})_{j,k=1}^N, \quad g \in U(N)
\]

(17)

where \( e^{i\theta_1}, \ldots, e^{i\theta_N} \) are the eigenvalues of \( g \). Then

\[
(\chi_\lambda : \lambda \in \mathbb{Z}^N, \lambda_1 \geq \cdots \geq \lambda_N)
\]

is a parametrization of the set of characters of irreducible representations of \( U(N) \). For characters \( \chi_\lambda \) and \( \chi_\mu \), we have

\[
\int_{U(N)} \chi_\lambda(g)\chi_\mu(g^*)dg = \int_{U(N)} \chi_\lambda(g)\chi_\mu(g^{-1})dg = \delta_{\lambda,\mu}
\]

and

\[
\Delta \chi_\lambda = -((\|\lambda + \rho\|^2 - \|\rho\|^2)\chi_\lambda).
\]

(19)
Moreover, the heat kernel \( p_t(g) : t \in (0, \infty), g \in U(N) \) is given by the following absolutely convergent sum

\[
p_t(g) = e^{\|\rho\|^2 t/2} \sum_{\lambda} \chi_\lambda(1) \chi_\lambda(g) e^{-\|\lambda + \rho\|^2 t/2}.
\]

The character values at the identity are given by the Weyl dimension formula

\[
\chi_\lambda(1) = \prod_{j,k = 1}^{N} \frac{\lambda_j + \rho_j - \lambda_k - \rho_k}{\rho_j - \rho_k}.
\]

The change of variable \( \mu = \lambda + \rho \) gives a convenient reparametrization of the set of characters by

\[
W = \{ \mu \in (\mathbb{Z}_{\text{sym}})^N : \mu_1 > \cdots > \mu_N \}.
\]

For \( x \in (\mathbb{Z}_{\text{sym}})^N \) with all components distinct, we will write \([x]\) for the decreasing rearrangement of \( x \). From (17), we see that,

\[
\chi_{x-\rho} = \varepsilon(x) \chi_{[x]-\rho}
\]

where

\[
\varepsilon(x) = \begin{cases} \text{sgn}(\sigma), & \text{if } x \text{ has all components distinct,} \\ 0, & \text{otherwise}, \end{cases}
\]

where \( \sigma \) is the unique permutation such that \([x]_j = x_{\sigma(j)} \) for all \( j \). Then the orthogonality relation (18) extends to all \( x, y \in (\mathbb{Z}_{\text{sym}})^N \) in the form

\[
\int_{U(N)} \chi_{x-\rho}(g) \chi_{y-\rho}(g^{-1}) dg = \varepsilon(x) \varepsilon(y) \delta_{[x],[y]}.
\]

To compute the desired moments of holonomy traces, we shall need the following product formula, which may be obtained from (17) by a straightforward computation. For all \( n \in \mathbb{Z} \), we have

\[
\chi_\lambda(g) \text{Tr}(g^n) = \sum_{j=1}^{N} \chi_{\lambda+n\omega_j}(g).
\]

Proof of Proposition 3.1. From the definition of the Yang–Mills measure, we have

\[
\mathbb{E}\left(\text{tr}(H_l^{-m})\text{tr}(H_l^{n})\right) \propto \int_{U(N)} p_a(g) \text{tr}(g^{-m}) \text{tr}(g^n) p_b(g^{-1}) dg.
\]
where $\propto$ signifies equality up to a constant independent of $m$ and $n$. We expand the heat kernel in characters to obtain

$$
\int_{U(N)} p_a(g) \text{tr}(g^{-m}) \text{tr}(g^n) p_b(g^{-1}) dg
\propto \sum_{\lambda, \mu \in W} e^{-\|\lambda\|^2 a/2 - \|\mu\|^2 b/2} \chi_{\lambda - \rho}(1) \chi_{\mu - \rho}(1)
$$

The interchange of summation and integration here is valid because $a, b > 0$ which ensures absolute convergence. By orthogonality of characters (22) and the product rule (23), for all $\lambda, \mu \in W$,

$$
\int_{U(N)} \chi_{\lambda - \rho}(g) \text{tr}(g^{-m}) \text{tr}(g^n) \chi_{\mu - \rho}(g^{-1}) dg
= \frac{1}{N^2} \sum_{j, k=1}^{N} \varepsilon(\lambda - m\omega^j) \varepsilon(\mu - n\omega^k) \delta_{[\lambda - m\omega^j], [\mu - n\omega^k]}
$$

Now, for $v \in W$, we have $[\lambda - m\omega^j] = [\mu - n\omega^k] = v$ for some $j, k \in \{1, \ldots, N\}$ if and only if $\lambda = [v + m\omega^j]$ and $\mu = [v + n\omega^k]$ for some $j', k' \in \{1, \ldots, N\}$, and then

$$
N\|\lambda\|^2 = N\|v\|^2 + 2mv_{j'} + m^2, \quad N\|\mu\|^2 = N\|v\|^2 + 2nv_{k'} + n^2
$$

and

$$
\varepsilon(\lambda - m\omega^j) = \varepsilon(v + m\omega^j), \quad \varepsilon(\mu - n\omega^k) = \varepsilon(v + n\omega^k')
$$

so, using the dimension formula (21),

$$
\chi_{\lambda - \rho}(1) \varepsilon(\lambda - m\omega^j) = \chi_{v + m\omega^j - \rho}(1) = \chi_{v - \rho}(1) \prod_{i \neq j} \frac{v_j + m - v_i}{v_j - v_i},
$$

$$
\chi_{\mu - \rho}(1) \varepsilon(\mu - n\omega^k) = \chi_{v + n\omega^k - \rho}(1) = \chi_{v - \rho}(1) \prod_{i \neq k} \frac{v_k + n - v_i}{v_k - v_i}.
$$

Hence

$$
\int_{U(N)} p_a(g) \text{tr}(g^{-m}) \text{tr}(g^n) p_b(g^{-1}) dg
\propto \sum_{v \in W} \prod_{j, k=1}^{N} (v_j - v_k)^2 e^{-\|v\|^2 T/2} J(v, m, a) J(v, n, b)
$$

where

$$
J(v, m, a) = e^{-m^2 a/(2N)} \frac{1}{N} \sum_{j=1}^{N} e^{-mv_{j} / N} \prod_{i \neq j} \frac{v_j + m - v_i}{v_j - v_i}.
$$
Note that \( J(\nu, 0, a) = 1 = I_0^a(\nu/N) \) and, for \(|m| \geq 1\),

\[
J(\nu, m, a) = \frac{e^{-m^2a/(2N)}}{2\pi im} \int_{N\gamma(\nu)} \prod_{j=1}^N \left( 1 + \frac{m}{z - \nu_j} \right) e^{-maz/N} dz
\]

\[
= \frac{e^{-m^2a/(2N)}}{2\pi im} \int_{\gamma(\nu)} \exp\{-m(a z - G_{\nu/N}^N(z))\} dz = I_m^a(\nu/N)
\]

where \( \gamma(\nu) \) is a positively oriented simple loop around \([\nu N/N, \nu_1/N] + \{z \in \mathbb{C} : |z| \leq |m|/N\}\).

So we obtain

\[
\mathbb{E}(\text{tr}(H_l^{-m})\text{tr}(H_l^n)) \propto \sum_{\nu \in \Lambda} \prod_{j<k} (\nu_j - \nu_k)^2 e^{-\|\nu\|^2T/2} I_m^a(\nu/N) I_n^b(\nu/N)
\]

\[
\propto \sum_{\lambda \in \Lambda} \prod_{j<k} (\lambda_j - \lambda_k)^2 \prod_{i=1}^N e^{-N\lambda_i^2T/2} I_m^a(\lambda_i) I_n^b(\lambda)
\]

\[
\propto \mathbb{E}(I_m^a(\Lambda) I_n^b(\Lambda)).
\]

Since the identity \( \mathbb{E}(\text{tr}(H_l^{-m})\text{tr}(H_l^n)) = \mathbb{E}(I_m^a(\Lambda) I_n^b(\Lambda)) \) holds for \( m = n = 0 \), it therefore holds for all \( m \) and \( n \). \( \square \)

The first part of the above proof follows ideas from the physics literature [6,14]. The use of contour integrals in writing the function \( J \) and in the formulation of Proposition 3.1 is new and provides us with a route to make rigorous the asymptotics performed in [6,14].

### 3.2. Concentration for the discrete \( \beta \)-ensemble and tightness of the support.

We shall need two facts about the discrete \( \beta \)-ensemble \( \Lambda \) defined in equation (16). Denote by \( \pi_N \) the law on \( M_1(\mathbb{R}) \) of the normalized empirical distribution

\[
\mu_\Lambda = \frac{1}{N} \sum_{i=1}^N \delta_{\Lambda_i}.
\]

Recall from (5) the functional

\[
\mathcal{I}_T(\mu) = \int_{\mathbb{R}^2} \left\{ \frac{1}{2}(x^2 + y^2)T - 2\log|x - y| \right\} \mu(dx)\mu(dy)
\]

defined for probability measures \( \mu \) on \( \mathbb{R} \) such that \( \mu([a, b]) \leq b - a \) for all intervals \([a, b]\). We extend \( \mathcal{I}_T \) to \( M_1(\mathbb{R}) \) by setting \( \mathcal{I}_T(\mu) = \infty \) if \( \mu \) does not satisfy this constraint. Guionnet and Maida [30] showed the following large deviation principle.

**Theorem 3.2.** The sequence of probability measures \( (\pi_N : N \in \mathbb{N}) \) satisfies a large deviation principle on \( M_1(\mathbb{R}) \) with rate function \( \mathcal{I}_T \) and speed \( N^2 \).
Let us remark that this result also allows to prove, for all $T \in (0, \infty)$, the existence of the limit

$$F(T) = \lim_{N \to \infty} N^{-2} \log(p_T^N(1))$$

(24)

where $p_T^N(1)$ denotes the heat kernel of $U(N)$ on the diagonal at time $T$. This approach was followed by Lévy and Maïda, who obtained in [43, Proposition 5.2] an exact formula for $F$. They showed moreover that $F$ is $C^2$ on $(0, \infty)$ and $C^\infty$ on $(0, \pi^2) \cup (\pi^2, \infty)$, but that the third derivative has a discontinuity at $\pi^2$. In doing so, they gave a rigorous proof of the Douglas–Kazakov phase transition [15] and of the fact that it is of third order. See also [7] for another approach using tools of statistical mechanics. We call $T \in (0, \pi^2)$ the subcritical regime and $T \in (\pi^2, \infty)$ the supercritical regime. We shall see in Sects. 6.1 and 6.2 that, in the limit $N \to \infty$, the behaviour of the eigenvalues of the unitary Brownian loop of length $T$ is very different in one regime to the other.

We need also a tightness result for the positions $\Lambda_N$ and $\Lambda_1$ of the leftmost and rightmost particles, which is obtained by a variation on ideas of Johansson [32]. See also Féral [20], who adapts to the discrete case some arguments of Ben Arous, Dembo and Guionnet [3, Section 6] for eigenvalues of GOE matrices.

**Lemma 3.3.** Set

$$\Lambda^* = \max\{|\Lambda_1|, |\Lambda_N|\}.$$

For all $a \in (0, \infty)$, there are constants $C, R < \infty$ depending only on $a$ and $T$ such that

$$\mathbb{E}\left(e^{a\Lambda^*} 1_{\{\Lambda^* \geq R\}}\right) \leq Ce^{-N}.$$

**Proof.** It will be convenient in this proof to label the particle positions in increasing order, where before we labelled them in decreasing order, so $\Lambda_N$ now denotes the position of the rightmost particle. Then, by symmetry, it will suffice to show that, for all $a \in [0, \infty)$, there are constants $C, R < \infty$ depending only on $a$ and $T$ such that

$$\mathbb{E}\left(e^{a\Lambda_N} 1_{\{\Lambda_N \geq R\}}\right) \leq Ce^{-N}.$$

Fix $N$ and, for $M \in \mathbb{N}$, set

$$Z_M = \sum_\lambda \prod_{j,k=1}^M (\lambda_j - \lambda_k)^2 \prod_{i=1}^M e^{-N\lambda_i^2 T/2}$$

where the sum is taken over the set $S_M$ of increasing sequences $\lambda = (\lambda_1, \ldots, \lambda_M)$ in $N^{-1}\mathbb{Z}_{\text{sym}}$. Only the cases $M = N - 1$ and $M = N$ will be considered further. In the following calculation, we write the possible values of $\Lambda = (\Lambda_1, \ldots, \Lambda_N)$ in the form $(\lambda, \lambda_N)$, where $\lambda = (\lambda_1, \ldots, \lambda_{N-1}) \in S_{N-1}$ and $\lambda_N \in N^{-1}\mathbb{Z}_{\text{sym}}$, and we write $\lambda^*$ for $\max\{|\lambda_1|, |\lambda_{N-1}|\}$. We have
$$\mathbb{E} \left( e^{a A_N} 1_{\{A^* = A_N \geq R\}} \right)$$

$$= \frac{1}{Z_N} \sum_{\lambda, \Lambda_N} \lambda \cdot e^{\lambda \Lambda_N} 1_{\{\lambda N \geq R, \lambda^* \leq \lambda_N\}} \prod_{j,k=1, j < k} (\lambda_j - \lambda_k)^2 \prod_{i=1}^N e^{-N \lambda_i^2 T / 2}$$

$$\leq \frac{1}{Z_N} \sum_{s} \sum_{\lambda} e^{as} 1_{\{s \geq R, \lambda^* \leq s\}} \prod_{j,k=1, j < k} (\lambda_j - \lambda_k)^2 \prod_{i=1}^N (s - \lambda_i)^2 \prod_{i=1}^N e^{-N \lambda_i^2 T / 2} e^{-Ns^2 T / 2}$$

$$\leq \frac{Z_{N-1}}{Z_N} \sum_{s} e^{as - Ns^2 T / 2} 1_{\{s \geq R\}} (4s^2)^{N-1}$$

where s and $\lambda_N$ are summed over $N^{-1} \mathbb{Z} \text{sym}$ and $\lambda$ is summed over $S_{N-1}$. We will show in Lemma 3.4 that there is a constant $c \in (0, \infty)$, depending only on $T$, such that

$$Z_{N-1} / Z_N \leq e^c N.$$ 

We can now choose $C, R \in (0, \infty)$, depending only on $a, c$ and $T$, so that

$$\sum_s e^{as - Ns^2 T / 2} 1_{\{s \geq R\}} (4s^2)^{N-1} \leq Ce^{-(c+1)N}$$

for all $N$, so obtaining the desired estimate

$$\mathbb{E} \left( e^{a A_N} 1_{\{A^* = A_N \geq R\}} \right) \leq Ce^{-N}.$$

$\square$

It remains to prove the following estimate, which limits the rate of decay of $Z_N$ as $N \to \infty$.

**Lemma 3.4.** There exists $c \in (0, \infty)$, depending only on $T$, such that, for all $N \geq 2$,

$$Z_{N-1} / Z_N \leq e^c N.$$ 

**Proof.** Let us consider again the set $S_{N-1}$ of increasing sequences $\lambda = (\lambda_1, \ldots, \lambda_{N-1})$ in $N^{-1} \mathbb{Z} \text{sym}$. For $\lambda \in S_{N-1}$, set

$$E(\lambda) = \prod_{j,k=1, j < k} (\lambda_j - \lambda_k)^2 \prod_{i=1}^N e^{-(N-1)T \lambda_i^2 / 2}$$

and set

$$A_N = \frac{1}{N} \sum_{\lambda \in S_{N-1}} e^{-Ts^2 / 2}, \quad E_N = \sup_{\lambda \in S_{N-1}} E(\lambda).$$

Note that

$$A_N \leq \frac{1}{N} + \int_{\mathbb{R}} e^{-Tx^2 / 2} dx \leq 1 + \sqrt{\frac{2\pi}{T}}.$$
We will show that, for \( r = 1 + 4/T \), there exists \( \lambda(N) \in S_{N-1} \) with \( \lambda(N)^* \leq r \) such that
\[
E_N = E(\lambda(N)).
\] (25)

Now
\[
Z_{N-1} = \sum_{\lambda \in S_{N-1}} \prod_{j<k} (\lambda_j - \lambda_k)^2 \prod_i e^{-NT\lambda_i^2/2} = \sum_{\lambda \in S_{N-1}} E(\lambda) \prod_i e^{-T\lambda_i^2/2}
\]
\[
\leq \sum_{\lambda \in S_{N-1}} E_N \prod_i e^{-T\lambda_i^2/2} = (N^N/N!) E_N A_{N-1}^{N-1} \leq e^N E_N A_{N-1}^{N-1}.
\]

On the other hand, there exists \( s \in N^{-1}\mathbb{Z}_{\text{sym}} \) with \( s \in [2r, 3r] \) so, by considering the single term in the sum where \( \lambda = (\lambda(N), s) \),
\[
Z_N = \sum_{\lambda \in S_N} \prod_{j<k} (\lambda_j - \lambda_k)^2 \prod_i e^{-NT\lambda_i^2/2}
\]
\[
\geq \prod_{j<k} (\lambda_j(N) - \lambda_k(N))^2 \prod_i (\lambda_i(N) - s)^2 \prod_i e^{-NT\lambda_i(N)^2/2} e^{-NTs^2/2}
\]
\[
= E_N \prod_i (\lambda_i(N) - s)^2 \prod_i e^{-T\lambda_i(N)^2/2} e^{-NTs^2/2}
\]
\[
\geq E_N e^{-(N-1)Tr^2/2} e^{-9NTr^2/2}.
\]

Hence
\[
Z_{N-1}/Z_N \leq e^N A_{N-1}^{N-1} e^{(N-1)Tr^2/2} e^{9NTr^2/2}
\]
which is a bound of the desired form.

It remains to show (25). To see this, given \( \lambda \in S_{N-1} \) with \( \lambda_{N-1} = \lambda^* = t \geq 1 + 4/T \), we can choose \( s \in N^{-1}\mathbb{Z}_{\text{sym}} \setminus \{\lambda_1, \ldots, \lambda_{N-2}\} \) with \(|s| \leq 1\) and consider the increasing rearrangement \( \tilde{\lambda} \) of \((\lambda_1, \ldots, \lambda_{N-2}, s)\). Note that
\[
\sum_{i=1}^{N-2} \log |s - \lambda_i| \geq \sum_{x \in N^{-1}\mathbb{Z}_{\text{sym}} \setminus \{|s|: |x-s| \leq 1\}} \log |s - x| \geq 2N \int_0^1 \log x \, dx = -2N
\]
whereas
\[
T(t^2 - 1)/2 - 2 \log t - 4 \geq T(t^2 - 1)/2 - 2t - 4 \geq 0.
\]

Then
\[
E(\lambda)/E(\tilde{\lambda}) \leq t^{2N} \prod_{i=1}^{N-2} (s - \lambda_i)^{-2} e^{-NT(t^2 - 1)/2}
\]
\[
\leq \exp(-N(T(t^2 - 1)/2 - 2 \log t - 4)) \leq 1.
\]

A similar argument applies if \( \lambda_1 = -\lambda^* \leq -1 - 4/T \). By iterating this procedure, we can find \( \mu \in S_{N-1} \) with \( \mu^* \leq 1 + 4/T \) and \( E(\mu) \geq E(\lambda) \). Since there are only finitely many sequences \( \mu \in S_{N-1} \) with \( \mu^* \leq 1 + 4/T \), this establishes the claim. □
3.3. Dimension-free continuity estimate for the holonomy of a simple loop. The following estimate will be needed for the proof of Proposition 2.7.

**Lemma 3.5.** There is a universal constant $K_T \in (0, \infty)$, in particular independent of $N$, such that, for any simple loop $l \in \text{Loop}(\mathbb{S}_T)$ dividing $\mathbb{S}_T$ into components of areas $a$ and $b$,

$$
\mathbb{E}(\text{tr}(I - H_l)) \leq K \min(a, b).
$$

From the following proof, it should be possible to show that $K_T$ is bounded as a function of $T$. We shall not use this fact and will not prove it here.

**Proof.** By symmetry, it suffices to consider the case $b \leq a$. Define, for each decreasing sequence $\lambda = (\lambda_1, \ldots, \lambda_N)$ in $N^{-1}\mathbb{Z}_{\text{sym}}$,

$$
D(b, \lambda) = \frac{1}{2\pi i} \int_{\gamma} e^{-b(z+1/(2N))} \exp\{G_N^{\lambda}(z)\} dz
$$

where $\gamma$ is a positively oriented simple loop around the set $[\lambda_N, \lambda_1] + \{z \in \mathbb{C} : |z| \leq 1/N\}$. We use the residue theorem to compute

$$
D(b, \lambda) = \frac{1}{N} \sum_{j=1}^{N} e^{-b(\lambda_j+1/(2N))} \prod_{i \neq j} \frac{\lambda_j + N^{-1} - \lambda_i}{\lambda_j - \lambda_i}.
$$

Note the identity

$$
\frac{1}{N} \sum_{j=1}^{N} \prod_{i \neq j} \frac{\lambda_j + N^{-1} - \lambda_i}{\lambda_j - \lambda_i} = 1. \quad (26)
$$

This may be seen, for example, by evaluating both sides of the product rule (23) for $\chi_{\rho + N\lambda}(g)\text{Tr}(g)$ at $g = 1$ using the dimension formula (21). Moreover, since $\lambda \in N^{-1}\mathbb{Z}_{\text{sym}}$, all the terms in the sum (26) are non-negative. Now, for all $j$,

$$
1 - e^{-b(\lambda_j+1/(2N))} \leq b|\lambda_j + 1/(2N)| \leq b(\lambda^* + 1/(2N))
$$

so

$$
1 - D(b, \lambda) = \frac{1}{N} \sum_{j=1}^{N} (1 - e^{-b(\lambda_j + 1/(2N))}) \prod_{i \neq j} \frac{\lambda_j + N^{-1} - \lambda_i}{\lambda_j - \lambda_i} \leq b(\lambda^* + 1/(2N)).
$$

But, by Proposition 3.1, we have

$$
\mathbb{E}(\text{tr}(H_l)) = \mathbb{E}(D(b, \Lambda))
$$

so

$$
\mathbb{E}(\text{tr}(I - H_l)) = \mathbb{E}(1 - D(b, \Lambda)) \leq b\left(\mathbb{E}(\Lambda^*) + \frac{1}{2N}\right)
$$

as required. $\square$
3.4. Evaluation of some contour integrals. In passing from the limit particle density \( \rho_T \) for the \( \beta \)-ensemble, as given in (8), to the evaluation of the master field on simple loops, we will need to evaluate certain contour integrals expressed in terms of the Stieltjes transform

\[
G_T(z) = \int_{\mathbb{R}} \frac{\rho_T(x)dx}{z-x}.
\]

The following calculation is taken from [6,14].

**Proposition 3.6.** Let \( T \in (0, \pi^2] \) and let \( a \in (0, T) \). Let \( \gamma \) be a positively oriented closed curve around the set \([-2/\sqrt{T}, 2/\sqrt{T}]\). Then, for all \( n \in (0, \infty) \),

\[
\frac{1}{2\pi in} \int_{\gamma} \exp\{-n(az - G_T(z))\}dz = \int_{\mathbb{R}} e^{inx} s_{a(T-a)/T}(x)dx
\]

where \( s_{t} \) is the semi-circle density (15) of variance \( t \).

**Proof.** Since \( T \in (0, \pi^2] \), we have \( \rho_T = s_{1/T} \). Then \( \rho_T(x) = \sqrt{T} \rho_1(\sqrt{T}x) \) so, by a scaling argument, it will suffice to consider the case \( T = 1 \). A standard calculation of the Stieltjes transform gives

\[
G_1(z) = \int_{\mathbb{R}} \frac{\rho_1(x)dx}{z-x} = \frac{z - \sqrt{z^2 - 4}}{2}.
\]

Note that \( G_1 \) maps \( \mathbb{C} \setminus [-2, 2] \) conformally to the punctured unit disc \( \mathbb{D} \setminus \{0\} \) with inverse \( z + 1/z \). Also, \( G_1(\gamma) \) is a negatively oriented closed curve around \( \{0\} \). Write \( b = 1 - a \).

We make the change of variable \( w = G_1(z) \) to obtain

\[
\frac{1}{2\pi in} \int_{\gamma} \exp\{-n(az - G_1(z))\}dz = \frac{1}{2\pi in} \int_{G_1(\gamma)} \exp\{n(bw - aw^{-1})\}(1 - w^{-2})dw
\]

\[
= \frac{1}{2\pi n} \int_0^{2\pi} \exp\{n(be^{-i\theta} - ae^{i\theta})(e^{i\theta} - e^{-i\theta})d\theta
\]

\[
= \frac{1}{2\pi n} \sum_{k=0}^{\infty} \frac{n^k}{k!} \sum_{j=0}^{k} \binom{k}{j} \int_0^{2\pi} (be^{-i\theta})^j (-ae^{i\theta})^{k-j}(e^{i\theta} - e^{-i\theta})d\theta
\]

\[
= \sum_{m=0}^{\infty} \frac{(-n^2ab)^m}{m!(m+1)!} = \int_{\mathbb{R}} e^{inx} s_{ab}(x)dx
\]

where we used in the last equality the moment formula

\[
\int_{\mathbb{R}} x^{2m} s_{t}(x)dx = \frac{t^{2m}}{m!(m+1)!}.
\]
More generally, for all $T \in (0, \infty)$, the following is obtained in [43, equation (4.12)]

$$
G_T(z) = \frac{zT}{2} - \frac{2}{\beta z} \sqrt{(z^2 - \alpha^2)(z^2 - \beta^2)} \int_0^1 \frac{ds}{(1 - \alpha^2 s^2/z^2)(1 - \beta^2 s^2)(1 - k^2 s^2)}
$$

where $k = \alpha/\beta \in (0, 1)$ and $\alpha, \beta$ are as defined in (7). Moreover, for $|x| \in [\alpha, \beta]$, in the limit $z \to x$ with $z \notin \mathbb{R}$, we have

$$
\text{Re}(G_T(z)) \to \lim_{\varepsilon \to 0} \int_{|y-x| \geq \varepsilon} \rho_T(y) dy = \frac{x T}{2}.
$$

**Proposition 3.7.** Let $T \in (0, \infty)$ and let $a, b \in (0, T)$ with $a + b = T$. Let $\gamma$ be a positively oriented closed curve around the set $[-\beta, \beta]$. Then, for all $n \in \mathbb{N}$,

$$
\frac{1}{2\pi in} \int_\gamma \exp(-n(az - G_T(z))) dz = \frac{2}{n \pi} \int_0^\infty \cosh[(a - b)nx/2] \sin(n \pi \rho_T(x)) dx
$$

$$
= \frac{1}{2\pi in} \int_{\gamma^{-1}} \exp(n(z - G_T(z))) dz.
$$

**Proof.** Since the integrand of the left-hand side is holomorphic in $\mathbb{C} \setminus [-\beta, \beta]$, we can take $\gamma$ to be the anti-clockwise boundary of $[-\beta - \varepsilon, \beta + \varepsilon] \times [-\varepsilon, \varepsilon]$ for any $\varepsilon > 0$. Now, as $\rho_T$ is Hölder continuous, by the Plemelj–Sokhotskyi formula [25], $G_T$ can be continuously extended, as $G_+$ and $G_-$ say, on $\mathbb{H} = \{z \in \mathbb{C} : \text{Im}(z) \geq 0\}$ and $-\mathbb{H}$, with

$$
G_\pm(x) = \lim_{\varepsilon \to 0} \int_{|y-x| \geq \varepsilon} \rho_T(y) dy \mp i \pi \rho_T(x) = \frac{x T}{2} \mp i \pi \rho_T(x)
$$

for any $x \in \mathbb{R}$. We can take the limit $\varepsilon \to 0$ in the contour integrals along $\gamma$ and $\gamma^{-1}$, using the dominated convergence theorem, to obtain

$$
\frac{1}{n \pi} \int_\mathbb{R} \exp((a - b)nx/2) \sin(n \pi \rho_T(x)) dx.
$$

Since $\rho_T$ is symmetric, this gives the claimed identity. \(\square\)

3.5. **Proof of Proposition 2.5.** Consider the discrete $\beta$-ensemble $\Lambda$ defined by (16). By Theorem 3.2,

$$
\mu_\Lambda \to \mu_T \quad \text{weakly in probability on } \mathbb{R} \text{ as } N \to \infty.
$$

Fix $n \in \mathbb{N}$. By Lemma 3.3, there exist $C, R \in (0, \infty)$, independent of $N$, such that

$$
\mathbb{E}(e^{2nT \Lambda^*} 1_{\Omega_R}) \leq C e^{-N}
$$

where

$$
\Lambda^* = \max(|\Lambda_1|, |\Lambda_N|), \quad \Omega_R = \{\text{supp}(\mu_\Lambda) \subseteq [-R, R]\} = \{\Lambda^* \leq R\}.
$$

We increase the value of $R$ if necessary so that

$$\text{supp}(\mu_T) \subseteq [-R, R].$$
Denote by $\gamma_R$ the positively oriented boundary of the set 
\[ [-R, R] + \{ z \in \mathbb{C} : |z| \leq 1 \}. \]
Recall that, for $\alpha \in (0, \infty)$ and $\text{dist}(z, \text{supp}(\mu_\Lambda)) > 1/\alpha$, we set
\[ G^\alpha_\Lambda(z) = \alpha \int_{\mathbb{R}} \log \left( 1 + \frac{1}{\alpha(z - x)} \right) \mu_\Lambda(dx). \]
For $N \geq n + 1$, the contour $\gamma_{R \cup \Lambda^*}$ contains the set 
\[ \text{supp}(\mu_\Lambda) + \{ z \in \mathbb{C} : |z| \leq n/N \} \]
so we can write, for $a \in (0, T)$,
\[
I^a_n(\Lambda) = e^{-an^2/(2N)} \frac{2\pi in}{2\pi in} \int_{\gamma_{R \cup \Lambda^*}} \exp\{-n(az - G^N_\Lambda(z))\}dz.
\]
Recall also that we set
\[ G_T(z) = \int_{\mathbb{R}} \frac{\mu_T(dx)}{z - x} \]
and, for $a, b > 0$ with $a + b = T$,
\[ I_n^a = I_n^b = \frac{2}{n\pi} \int_0^\infty \cosh \{(a - b)nx/2\} \sin\{n\pi \rho_T(x)\}dx \]
and that, by Proposition 3.7,
\[ I_n^a = \frac{1}{2\pi in} \int_{\gamma_R} \exp\{-n(az - G_T(z))\}dz. \]
In Proposition 3.1 we showed that, for any simple loop $l \in \text{Loop}(\mathbb{S}_T)$ which divides $\mathbb{S}_T$ into components of areas $a$ and $b$,
\[ \mathbb{E}(\text{tr}(H^n_l)) = \mathbb{E}(I_n^a(\Lambda)) = \mathbb{E}(I_n^b(\Lambda)) \]
and
\[ \mathbb{E}(|\text{tr}(H^n_l)|^2) = \mathbb{E}(\text{tr}(H^{-n}_l)\text{tr}(H^n_l)) = \mathbb{E}(I_n^a(\Lambda)I_n^b(\Lambda)). \]
We will show that, for all $n \in \mathbb{N}$, in the limit $N \to \infty$, uniformly in $a \in (0, T)$,
\[ \mathbb{E}(I_n^a(\Lambda)) \to I_n^a, \quad \mathbb{E}(I_n^a(\Lambda)I_n^b(\Lambda)) \to I_n^aI_n^b. \] (31)
Then
\[ \mathbb{E}(\text{tr}(H^n_l)) \to I_n^a, \quad \mathbb{E}(|\text{tr}(H^n_l)|^2) \to |I_n^a|^2 \]
so
\[ \mathbb{E}(|\text{tr}(H^n_l) - I_n^a|^2) = \mathbb{E}(|\text{tr}(H^n_l)|^2) - 2\mathbb{E}(\text{tr}(H^n_l))I_n^a + |I_n^a|^2 \to 0 \]
as required.
The following estimates hold for $|w| \leq 1/2$

$$|\Log(1 + w)| \leq 2|w|, \quad |\Log(1 + w) - w| \leq |w|^2.$$ 

We apply these estimates with $w = n/(N(z - x))$, for $N \geq 2n$ and for points $z$ on the contour $\gamma_R \vee \Lambda^*$ and $x$ in the support of $\mu_\Lambda$, to obtain

$$|G_A^{N/n}(z)| \leq 2, \quad |G_A^{N/n}(z) - G_A(z)| \leq n/N$$

where

$$G_A(z) = \int_{\mathbb{R}} \frac{\mu_\Lambda(dx)}{z - x}.$$ 

Note that $\gamma_R$ has length $4R + 2\pi$. By some straightforward estimation, on $\Omega^R_c$,

$$|I^a_n(\Lambda)| \leq \frac{1}{2\pi n}(4\Lambda^* + 2\pi)e^{nT(A^*+1)+2n}$$

while, on $\Omega_R$,

$$|I^a_n(\Lambda)| \leq \frac{1}{2\pi n}(4R + 2\pi)e^{nT(R+1)+2n}.$$ 

Then, by the estimate (30), uniformly in $a \in (0, T)$,

$$\mathbb{E}(|I^a_n(\Lambda)|1_{\Omega^R_c}) \to 0, \quad \mathbb{E}(|I^a_n(\Lambda)I^b_n(\Lambda)|1_{\Omega^R_c}) \to 0.$$ 

On the other hand, on the event $\Omega_R$, we have

$$I^a_n(\Lambda) = \frac{e^{-an^2/(2N)}}{2\pi in} \int_{\gamma_R} \exp\{-n(az - G_A^{N/n}(z))\}dz.$$ 

Hence, the weak limit (29) implies that, uniformly in $a \in (0, T)$,

$$I^a_n(\Lambda)1_{\Omega_R} \to \frac{1}{2\pi in} \int_{\gamma_R} \exp\{-n(az - G_T(z))\}dz = I^a_n$$

in probability, and so

$$\mathbb{E}(I^a_n(\Lambda)1_{\Omega_R}) \to I^a_n, \quad \mathbb{E}(I^a_n(\Lambda)I^b_n(\Lambda)1_{\Omega_R}) \to I^a_n I^b_n.$$ 

The desired limits (31) now follow. □

4. Makeenko–Migdal Equations

Our aim in this section is to prove Proposition 2.6. For this, our main tool will be the Makeenko–Migdal equations. In order to formulate these precisely, we first give a description of the set of regular loops modulo area-preserving homeomorphisms of $S_T$. This allows to reduce our analysis to a series of finite-dimensional simplices, each representing the possible vectors of face-areas for a given combinatorial graph. We show that the Makeenko–Migdal equations allow us to move area between faces of a regular loop provided only that the total area and the total winding number are conserved. This finally allows an inductive scheme to bootstrap the convergence we have shown for simple loops to all regular loops.
4.1. Combinatorial planar graphs and loops. Recall from Sect. 2.1 the notion of a labelled embedded graph. Given two labelled embedded graphs $G = (e_1, \ldots, e_m)$ and $G' = (e'_1, \ldots, e'_m)$, let us write $G \sim G'$ if there is an orientation-preserving homeomorphism $\theta$ of $S_T$ such that $e'_j = \theta \circ e_j$ for all $j$. Further, let us write $G \approx G'$ if $\theta$ may be chosen to be area-preserving. Then $\sim$ and $\approx$ are equivalence relations on the set of labelled embedded graphs. We will call the equivalence class of $G$ under $\sim$ the combinatorial graph associated to $G$.

We define a standard labelling of the vertices and faces of $G$ as follows. Consider the sequence of vertices $(e_1, \ldots, e_m)$ and write $V = (v_1, \ldots, v_q)$ for the subsequence obtained by dropping any vertex which has already appeared. Similarly consider the sequence of faces $(l(e_1), r(e_1), \ldots, l(e_m), r(e_m))$, where $l(e_j)$ and $r(e_j)$ are the connected components of $S_T \setminus \{e_1^*, \ldots, e_m^*\}$ to the left and right of $e_j$. Then write $F = (f_1, \ldots, f_p)$ for the subsequence obtained by dropping any face which has already appeared. See Fig. 4 for an example. Set

$$V = \{1, \ldots, q\}, \quad E = \{1, \ldots, m\}, \quad F = \{1, \ldots, p\}.$$

The combinatorial graph associated to $G$ is then characterized by the integers $q, m, p$ and the functions $s, t : E \to V$ and $l, r : E \to F$ given by

(a) $s(j) = i$ if $v_i$ is the starting point of $e_j$,
(b) $t(j) = i$ if $v_i$ is the terminal point of $e_j$,
(c) $l(j) = k$ if $f_k$ is the face to the left of $e_j$,
(d) $r(j) = k$ if $f_k$ is the face to the right of $e_j$.

We call any quadruple $G = (s, t, l, r)$ which arises in this way a combinatorial planar graph. We freely identify $G$ with the corresponding equivalence class of labelled embedded graphs.

---

5 To see this, given $G'$ with the same combinatorial data, we can first define homeomorphisms $e^*_j \to e'_j$ by parametrization at constant speed, then extend the resulting homeomorphisms of face-boundaries to homeomorphisms of closed faces to obtain a homeomorphism of $S_T$. 

---

Fig. 4. A labelled embedded graph of a regular loop (see definition on page 8), with the standard labelling written on vertices and faces.
Given a combinatorial planar graph $G$, consider the simplex

$$\Delta_G(T) = \{(a_1, \ldots, a_p) : a_k > 0 \text{ for all } k \text{ and } a_1 + \cdots + a_p = T\}.$$ 

Given a labelled embedded graph $\mathbb{G} \in G$, define the face-area vector $a(\mathbb{G}) = (a_1, \ldots, a_p)$ by

$$a_k = \text{area}(f_k).$$

Then $a(\mathbb{G}) \in \Delta_G(T)$. For $a \in \Delta_G(T)$, set

$$\mathcal{G}(a) = \{\mathbb{G} \in G : a(\mathbb{G}) = a\}. $$

The sets $\mathcal{G}(a)$ are then the equivalence classes of the relation $\approx$. We call a sequence $l_0 = ((j_1, \varepsilon_1), \ldots, (j_r, \varepsilon_r))$ in $E \times \{-1, 1\}$ a loop in $G$ if

$$t(j_k, \varepsilon_k) = s(j_{k+1}, \varepsilon_{k+1})$$

for $k = 1, \ldots, r$, where $j_{r+1} = j_1$ and $\varepsilon_{r+1} = \varepsilon_1$ and where

$$s(j, \varepsilon) = t(j, -\varepsilon) = \begin{cases} s(j), & \text{if } \varepsilon = 1, \\ t(j), & \text{if } \varepsilon = -1. \end{cases}$$

The condition (32) means that, in any labelled embedded graph $\mathbb{G} = (e_1, \ldots, e_m) \in \mathcal{G}$, we can concatenate the sequence of edges $(e_{j_1}^{\varepsilon_1}, e_{j_2}^{\varepsilon_2}, \ldots, e_{j_r}^{\varepsilon_r})$ to form a loop

$$l_0 = e_{j_1}^{\varepsilon_1} e_{j_2}^{\varepsilon_2} \cdots e_{j_r}^{\varepsilon_r}.$$ 

We call the loop $l_0$ so obtained the drawing of $l_0$ in $\mathbb{G}$. Note that the sequence

$$l^{-1} = ((j_r, -\varepsilon_r), \ldots, (j_1, -\varepsilon_1))$$

is then also a loop in $\mathcal{G}$, whose drawing in $\mathbb{G}$ is the reversal $l^{-1}$ of $l$. Note also the obvious notion of concatenation for loops in $\mathcal{G}$.

In the case of interest to us, $\mathcal{G}$ will be the combinatorial graph of the labelled embedded graph $\mathbb{G} = (e_1, \ldots, e_m)$ of a regular loop $l$. We write then $a(l)$ for $a(\mathbb{G})$. If $l$ has $n$ self-intersections, we have $q = n + 1$, $m = 2n + 1$ and, by Euler’s relation, $p = n + 2$. Note that the set of self-intersections is given in the standard labelling by $\{v_i : i \in I\}$, where $I = \{2, 3, \ldots, n + 1\}$. We recover $l$ as the drawing in $\mathbb{G}$ of the loop

$$l = ((1, 1), \ldots, (2n + 1, 1))$$

in $\mathcal{G}$. We call the pair $(\mathcal{G}, l)$ a combinatorial planar loop. For each $n \geq 0$, there are only finitely many combinatorial loops with $n$ self-intersections. We will write abusively $l$ for $(\mathcal{G}, l)$, $\Delta_l(T)$ for $\Delta_G(T)$ and $l(a)$ for $\mathcal{G}(a)$. Given a loop $l_0$ in $\mathcal{G}$, it may be that the drawing $l_0$ of $l_0$ in $\mathcal{G}$ is a regular loop. We could then consider the combinatorial loop associated to $l_0$, without reference to its relation to $\mathcal{G}$. We will therefore need to make clear when such a combinatorial loop is to be considered in the context of a larger combinatorial graph. We shall also write $l_0 \in l(a)$ whenever $l_0 \in \text{Loop}_n(G)$ is a drawing of $l$ in a graph belonging to $l(a)$, for some area vector $a$. Given $n \geq 0$ and a function $\Phi : \text{Loop}_n(G) \to \mathbb{C}$ which is invariant under area-preserving homeomorphisms, for any combinatorial planar loop $l$ having $n$ self-intersections, we can define a quotient map $\phi_l : \Delta_l(T) \to \mathbb{C}$ by setting

$$\phi_l(a) = \Phi(l)$$

where $l$ is any loop in $l(a)$. We say that $\Phi$ is uniformly continuous in area if the map $\phi_l : \Delta_l(T) \to \mathbb{C}$ is uniformly continuous for all such combinatorial loops $l$.
4.2. Generalized Makeenko–Migdal equations. Let \( l \) be a combinatorial planar loop. Write \( m \) and \( p \) for the numbers of edges and faces in the associated combinatorial graph. Let \( H = (H_\gamma : \gamma \in \text{Path}(S_T)) \) be a Yang–Mills holonomy field in \( U(N) \).

**Proposition 4.1.** Let \( f : U(N)^m \to \mathbb{C} \) be a continuous bounded function. Then we can define a function \( E(f) : \Delta_1(T) \to \mathbb{C} \) by

\[
E(f)(a) = \frac{1}{p_T(1)} \int_{U(N)^m} f(g_1, \ldots, g_m) \prod_{k=1}^p p_{ak}(\tilde{g}_k) \prod_{j=1}^m dg_j
\]

where \( \tilde{g}_k \) is the holonomy around \( f_k \) obtained from the edge holonomies \( g_1, \ldots, g_m \). Moreover \( E(f) \) is uniformly continuous on \( \Delta_1(T) \) and

\[
E(f)(a) = \mathbb{E}(f(H_{e_1}, \ldots, H_{e_m}))
\]

for \( a \in \Delta_1(T) \), whenever \( \mathbb{G} = (e_1, \ldots, e_m) \) is a labelled embedded graph with \( \mathbb{G} \in l(a) \).

**Proof.** The function \( E(f) \) is well defined because \( p_{a}(g) = p_{a}(g^{-1}) = p_{a}(ghg^{-1}) \), which ensures that the right-hand side does not depend on the choices of starting point and direction for the loop holonomy \( \tilde{g}_k \). It will suffice to show uniform continuity on each of the sets

\[
\Delta_k = \{ a \in \Delta_1(T) : a_k \geq T/p \}.
\]

Then, by symmetry, it will suffice to consider the case \( k = p \). Given a family of edge holonomies \( g = (g_1, \ldots, g_m) \in U(N)^m \), for each face \( f_k \), choose an adjacent edge and denote by \( \tilde{g}_k \) the holonomy around \( f_k \) starting from that edge. Fix also edge labels \( i_1, \ldots, i_{m-p+1} \) such that the edges \( e_{i_1}, \ldots, e_{i_{m-p+1}} \) form a spanning tree of the associated graph. Define, for \( k = 1, \ldots, p-1 \) and \( j = 1, \ldots, m-p+1 \),

\[
b_k = \tilde{g}_k, \quad h_j = g_{i_j}.
\]

Then the map \( g \mapsto (b, h) : U(N)^m \to U(N)^m \) preserves the \( m \)-fold product of Haar measure. Moreover, the edge holonomies \( g_1, \ldots, g_m \) and the loop holonomy \( \tilde{g}_p \) for \( f_p \) are given by finite products of \( b_1, \ldots, b_{p-1} \) and \( h_1, \ldots, h_{m-p+1} \) and their inverses. See [40, Proposition 2.4.2]. Hence we have

\[
E(f)(a) = \frac{1}{p_T(1)} \int_{U(N)^m} f(g_1(b, h), \ldots, g_m(b, h)) p_{a_p}(\tilde{g}_p(b, h)) \prod_{k=1}^{p-1} p_{ak}(b_k) db_k \prod_{j=1}^{m-p+1} dh_j
\]

\[
= \frac{1}{p_T(1)} \mathbb{E} \int_{U(N)^{m-p+1}} f(g_1(B, h), \ldots, g_m(B, h)) p_{a_p}(\tilde{g}_p(B, h)) \prod_{j=1}^{m-p+1} dh_j
\]

(33)

where \( B = (B^{1}_{a_1}, \ldots, B^{p-1}_{a_{p-1}}) \) and \( B^{1}, \ldots, B^{p-1} \) are independent Brownian motions in \( G \) starting from \( 1 \). Now, on \( \Delta_p \), we have \( a_p \geq T/p \), so the claimed uniform continuity follows from standard continuity estimates for Brownian motion and the heat kernel in \( G \). \( \square \)
For \( i \in \{1, \ldots, m\} \) and \( g \in U(N) \), define maps \( R_{i,g} \) and \( \hat{R}_{i,g} \) on \( U(N)^m \) by
\[
R_{i,g}(h_1, \ldots, h_m) = (h_1, \ldots, h_{i,g}, \ldots, h_m),
\]
\[
\hat{R}_{i,g}(h_1, \ldots, h_m) = (h_1, \ldots, g^{-1}h_i, \ldots, h_m).
\]
For \( i \in \{1, \ldots, m\} \) and \( X \in u(N) \), define a differential operator \( \mathcal{L}_X^i \) on \( U(N)^m \) by
\[
\mathcal{L}_X^i(f) = \frac{d}{dt} \bigg|_{t=0} f \circ R_{i,e^tX}.
\]
Choose an orthonormal basis \( (X_n : n = 1, \ldots, N^2) \) for \( u(N) \) (with inner product \( (1) \)) and, for \( i, j \in \{1, \ldots, m\} \), define
\[
\Delta_{i,j}(f) = \sum_n \mathcal{L}_{X_n}^i \circ \mathcal{L}_{X_n}^j(f).
\]
The operator \( \Delta_{i,j} \) does not depend on the choice of orthonormal basis.

A function \( f : U(N)^m \to \mathbb{C} \) is said to have **extended gauge invariance** if, for all \( g \in U(N) \) and for \( i = 1, \ldots, m-1 \),
\[
f \circ \hat{R}_{i,g} \circ R_{i+1,g} = f.
\]
Thus we require
\[
f(h_1, \ldots, g^{-1}h_i, h_{i+1}g, \ldots, h_m) = f(h_1, \ldots, h_i, h_{i+1}, \ldots, h_m).
\]
Recall that
\[
\Delta_1(T) = \{(a_1, \ldots, a_{n+2}) : a_k > 0 \text{ for all } k \text{ and } a_1 + \cdots + a_{n+2} = T\}.
\]
Write \( \mathcal{I} \) for the set of intersection labels and \( \mathcal{F} \) for the set of face labels in the combinatorial graph \( \mathcal{G} \) of \( l \), as usual. For \( i \in \mathcal{I} \), define a (constant) vector field \( \mathcal{E}_i \) on \( \Delta_1(T) \) as follows. Choose \( \mathcal{G} \in \mathcal{G} \) and write \( l \) for the drawing of \( l \) in \( \mathcal{G} \). In the standard labelling of \( \mathcal{G} \), the vertex \( v_i \) is a self-intersection of \( l \). Write \( (k_1, k_2, k_3, k_4) \) for the labels of the faces found on making a small anti-clockwise circuit around \( v_i \), starting in the face \( f_{k_1} \) adjacent to two outgoing edges, and in the corner adjacent to those edges. Note that the case \( k_1 = k_3 \) can arise, but the condition that we start in the corner adjacent to the outgoing edges allows us to specify the sequence \( (k_1, k_2, k_3, k_4) \) uniquely in any case. In the example of Fig. 4, if \( i = 2 \), then \( k_1 = k_3 = 1 \), \( k_2 = 3 \) and \( k_4 = 2 \). This sequence does not depend on the choice of \( \mathcal{G} \). Set
\[
\mathcal{E}_i = \partial_{k_1} - \partial_{k_2} + \partial_{k_3} - \partial_{k_4}
\]
where \( \partial_k = \partial/\partial a_k \) denotes the elementary vector field in direction \( k \). Note that \( \mathcal{E}_i \) is tangent to the simplex \( \Delta_1(T) \).

The following theorem is a specialization of a result of Driver, Gabriel, Hall and Kemp [18, Theorem 2], which generalizes a formulation of Lévy [41].

**Theorem 4.2.** Let \( f : U(N)^m \to \mathbb{C} \) be a \( C^\infty \) function having extended gauge invariance. Then, for all \( i \in \mathcal{I} \), the function \( E(f) \) has a directional derivative on \( \Delta_1(T) \) in direction \( \mathcal{E}_i \) given by
\[
\mathcal{E}_i E(f) = -E(\Delta_{j_1,j_2}(f))
\]
where \( j_1, j_2 \) are determined by \( s(j_1) = s(j_2) = i \).
4.3. Makeenko–Migdal equations for Wilson loops. Given a loop $l_0 = ((j_1, \varepsilon_1), \ldots, (j_r, \varepsilon_r))$ in $\mathcal{G}$, we can define a continuous bounded function $W_{l_0} : U(N)^m \to \mathbb{C}$ by

$$W_{l_0}(h_1, \ldots, h_m) = \text{tr}(h_{e_{r_j}} \ldots h_{e_{j_1}}).$$

Given a sequence of loops $(l_1, \ldots, l_k)$ in $\mathcal{G}$, define the Wilson loop function

$$\phi^N_{l_1, \ldots, l_k} : \Delta_I(T) \to \mathbb{C}$$

by

$$\phi^N_{l_1, \ldots, l_k} = E(W_{l_1} \ldots W_{l_k}).$$

Then $\phi^N_{l_1, \ldots, l_k}$ is uniformly continuous and, for all $a \in \Delta_I(T)$ and all $G \in I(a)$,

$$\phi^N_{l_1, \ldots, l_k}(a) = \mathbb{E}(\text{tr}(H_{l_1}) \ldots \text{tr}(H_{l_k}))$$

(35)

where $l_1, \ldots, l_k$ are the drawings of $l_1, \ldots, l_k$ in $\mathcal{G}$.

For $i \in I$, we obtain two regular loops $l_i$ and $\hat{l}_i$ by splitting $l$ at $v_i$, that is, by following the two outgoing strands of $l$ from $v_i$ until their first return to $v_i$. In one case we will pass through the endpoint of $l$ and begin another circuit of $l$ until we reach $v_i$. Write $l_i$ and $\hat{l}_i$ for the loops in $\mathcal{G}$ whose drawings in $\mathcal{G}$ are $l_i$ and $\hat{l}_i$, which do not depend on the choice of $\mathcal{G}$. Then set

$$[l]_i = l_i \hat{l}_i l_i^{-1} \hat{l}_i^{-1}, \quad [\hat{l}]_i = \hat{l}_i l_i \hat{l}_i^{-1} l_i^{-1}$$

where $l_i^{-1}, \hat{l}_i^{-1}$ denote the reversals of $l_i, \hat{l}_i$ and the right-hand sides are understood as concatenations.

**Proposition 4.3** (Makeenko–Migdal equations for Wilson loops). The functions $\phi^N_{l_i}$ and $\phi^N_{l_i l_i^{-1}}$ have directional derivatives in $\Delta_I(T)$ in direction $\mathcal{E}_i$ given by

$$\mathcal{E}_i \phi^N_{l_i} = \phi^N_{l_i, l_i}, \quad \mathcal{E}_i \phi^N_{l_i l_i^{-1}} = \phi^N_{l_i, l_i l_i^{-1}} + \phi^N_{l_i l_i^{-1}, l_i} - N^{-2}(\phi^N_{l_i} + \phi^N_{l_i^{-1}}).$$

**Proof.** We give details only for $\phi^N_{l_i l_i^{-1}}$. The simpler argument for $\phi^N_{l_i}$ will then be obvious.

The argument for $\phi^N_{l_i}$ already appeared after Theorem 2.6 in [19] and in Section 9.2 of [41]. Given $\mathcal{G} = (e_1, \ldots, e_m) \in \mathcal{G}$, set $l = e_1 \ldots e_m$, so $l$ is the drawing of $l$ in $\mathcal{G}$. Given $h = (h_1, \ldots, h_m) \in U(N)^m$, there is a unique multiplicative function

$$(h_\gamma : \gamma \in \text{Path}(\mathcal{G})) \in \text{Mult}(\text{Path}(\mathcal{G}), U(N))$$

such that $h_{e_j} = h_j$ for all $j$. Then $\phi^N_{l_i l_i^{-1}} = E(f)$, where $f = |W_l|^2$ and

$$W_l(h_1, \ldots, h_m) = \text{tr}(h_l) = \text{tr}(h_m \ldots h_1).$$

Note that $W_l$ has extended gauge invariance and so also does $f$. We can write $l_i = e \gamma$ and $\hat{l}_i = \hat{e} \hat{\gamma}$, where $e = e_{j_1}, \hat{e} = e_{j_2}, s(j_1) = s(j_2) = i$ and $\gamma, \hat{\gamma} \in \text{Path}(\mathcal{G})$. Then

$$f(h) = \text{tr}(h_l) \text{tr}(h_{l_i}^{-1}) = \text{tr}(h_\gamma h_\hat{\gamma} h_e h_\hat{e}) \text{tr}(h_e^{-1} h_\hat{\gamma}^{-1} h_\hat{e}^{-1} h_\gamma^{-1}).$$
For $X \in u(N)$,
\[
L^j_X \circ L^j_X(f)(h) = \text{tr}(h_\gamma h_\epsilon X h_\gamma h_\epsilon X) + \text{tr}(h_1)\text{tr}(X h_\epsilon^{-1} h_\gamma^{-1} X h_\epsilon^{-1} h_\gamma^{-1}) \\
- \text{tr}(h_\gamma h_\epsilon h_\gamma h_\epsilon X) + \text{tr}(h_1)\text{tr}(X h_\epsilon^{-1} h_\gamma^{-1} X h_\epsilon^{-1} h_\gamma^{-1}) \\
- \text{tr}(h_\gamma h_\epsilon X h_\gamma h_\epsilon X) + \text{tr}(X h_\epsilon^{-1} h_\gamma^{-1} X h_\epsilon^{-1} h_\gamma^{-1}).
\]

Write $E_{j,k}$ for the elementary matrix with a 1 in the $(j,k)$-entry. Set
\[
X_{j,j} = iE_{j,j}/\sqrt{N}, \quad X_{j,k} = \begin{cases} (E_{j,k} - E_{k,j})/\sqrt{2N}, & \text{for } j < k, \\ i(E_{j,k} + E_{k,j})/\sqrt{2N}, & \text{for } j > k. \end{cases}
\]
Then $\{X_{j,k}: j, k = 1, \ldots, N\}$ is an orthonormal basis in $u(N)$. A simple calculation gives the standard identity
\[
\sum_{j,k=1}^N X_{j,k} \otimes X_{j,k} = -\frac{1}{N} \sum_{j,k=1}^N E_{j,k} \otimes E_{k,j}.
\]

We sum to obtain
\[
-\Delta_{j_1,j_2}(f)(h) = \text{tr}(h_\gamma h_\epsilon)\text{tr}(h_\gamma h_\epsilon)\text{tr}(h_1^{-1}) + \text{tr}(h_1)\text{tr}(h_\epsilon^{-1} h_\gamma^{-1})\text{tr}(h_1^{-1} h_\gamma^{-1}) \\
- \frac{1}{N^2}\text{tr}(h_\gamma h_\epsilon h_\gamma h_\epsilon h_\epsilon^{-1} h_\gamma^{-1} h_\epsilon^{-1} h_\gamma^{-1}) \\
- \frac{1}{N^2}\text{tr}(h_\gamma h_\epsilon h_\gamma h_\epsilon h_\epsilon^{-1} h_\gamma^{-1} h_\epsilon^{-1} h_\gamma^{-1})
\]
and hence, by Theorem 4.2,
\[
\mathcal{E}_l\phi^N_{l,l^{-1}} = -E(\Delta_{j_1,j_2}(f)) = \phi^N_{l_{i_1},i_{i_1},l^{-1}} + \phi^N_{l_{i_1},i_{i_1},l^{-1}} - N^{-2}(\phi^N_{l_{i_1}}, + \phi^N_{l_{i_1}}).
\]

4.4. Makeenko–Migdal vectors and the winding number. Let $l \in \text{Loop}(\mathbb{S}_T)$ be a regular loop and let $\mathbb{G} = (V, E, F)$ be the associated labelled embedded graph. For any pair of faces $f_0, f_s \in F$ and points $x_0 \in f_0, x \in f_s$, the set $\mathbb{S}_T \setminus \{x_0, x_s\}$ can be retracted to a simple closed curve $s$ in $\mathbb{S}_T$ which winds positively around $x_s$ and negatively around $x_0$. Furthermore, there is a unique $n_l(f_0, f_s) \in \mathbb{Z}$ such that $l$ is homotopic within $\mathbb{S}_T \setminus \{x_0, x_s\}$ to $s^{n_l(f_0, f_s)}$. The integer $n_l(f_0, f_s)$ does not depend on the choice of $x_0, x_s$ but only on $f_0, f_s$. Setting $n_l(f, f) = 0$ for any $f \in F$, this defines a skew symmetric function $n_l: F^2 \to \mathbb{Z}$. Fixing an orientation preserving homeomorphism from $\mathbb{S}_T \setminus \{x_0\}$ to $\mathbb{R}^2$, for each face $f \in F$, $n_l(f_0, f)$ is the winding number of the image of $l$ around the image of $f$ in the plane $\mathbb{R}^2$. This number can be computed as follows. Given a track from $f_0$ to $f$, comprising edges $e_1, \ldots, e_k$ and faces $f_1, \ldots, f_k$ such that $f_k = f$ and $e_j$ is adjacent to both $f_{j-1}$ and $f_j$ for all $j$, we have
\[
n_l(f_0, f) = L(f) - R(f)
\]
Fig. 5. A track between two faces $f_0$ and $f$ is drawn with dashed lines. The value of the winding number for the choice of $f_0$ is printed on each face.

where $L(f)$ and $R(f)$ are the numbers of edges $e_j$ with $f_j$ on the left and right respectively. (The notation here does not refer to the standard labelling of $\mathbb{G}$.) This construction yields the following observation: for any $f_0, f_* \in F$,

$$n_l(f_0, f) + n_l(f, f_*) = n_l(f_0, f_*) = -n_l(f_*, f_0).$$

It follows that the function $f \mapsto n_l(f_0, f)$ depends on the choice of face $f_0$ only through the addition of a constant. We shall denote it abusively as well by $n_l$ and call it the \textit{winding number function} of $l$. See Fig. 5 for an example.

The winding number is invariant under orientation-preserving homeomorphisms of $S_T$, so, using the notations introduced in Sect. 4.1, we obtain also a function

$$n_l : \mathcal{F} \rightarrow \mathbb{Z}$$

determined by the associated combinatorial loop $l$, also defined up to an additive constant, by setting

$$n_l(k) = n_l(f)$$

where $f$ is the $k$th face in the standard labelling of $\mathbb{G}$.

The following lemma is a reformulation of a lemma of Lévy [41, Lemma 6.28]. See also Dahlqvist [13, Lemma 21]. We give a slightly different proof, relying on properties of the winding number in place of a dimension-counting argument. The prior results were stated for the whole plane, while ours applied to the sphere, but this make little difference to the argument.

\textbf{Lemma 4.4.} There is an orthogonal direct sum decomposition

$$\mathbb{R}^\mathcal{F} = m_l \oplus n_l$$

where

$$m_l = \text{span}\{\mathcal{E}_i : i \in I\}, \quad n_l = \text{span}\{1, n_l\}.$$
Proof. Note first that \(1^T \Xi_i = 1 - 1 + 1 - 1 = 0\) for all \(i\). Let \(i \in \mathcal{I}\). Write \(k_1, k_2, k_3, k_4\) for the faces at \(i\), listed anticlockwise starting from the face \(k_1\) adjacent to both outgoing edges. Then the values of \(n_1\) at \(k_1, k_2, k_3, k_4\) are given respectively by \(n, n + 1, n, n - 1\) for some \(n\), so

\[n_1^T \Xi_i = n_1(k_1) - n_1(k_2) + n_1(k_3) - n_1(k_4) = 0.\]

Hence, if \(\alpha \in m_i\), then \(1^T \alpha = 0\) and \(n_1^T \alpha = 0\).

Suppose on the other hand that \(\alpha \in m_i^\perp\). Consider the 1-forms (of the dual graph) \(d\alpha\) and \(d\nu\), given by

\[d\alpha(j) = \alpha(l(j)) - \alpha(r(j)), \quad dn_1(j) = n_1(l(j)) - n_1(r(j)), \quad j \in \mathcal{E}.\]

Then \(dn_1(j) = 1\) for all \(j\). On the other hand, for \(j = 1, \ldots, m - 1\), there is an \(i_j \in \mathcal{I}\) such that \(t(j) = i_j = s(j + 1)\), so

\[d\alpha(j) - d\alpha(j + 1) = \pm \Xi_i^T \alpha = 0.\]

Hence \(d\alpha = c_1dn_1\) and so \(\alpha = c_1n_1 + c_2\) for some constants \(c_1, c_2\). \(\Box\)

Note that \(\Delta_1(T)\) is convex, and that, by counting dimensions, the vectors \(\{\Xi_i : i \in \mathcal{I}\}\) are linearly independent. We deduce from these facts, and the preceding lemma the following proposition. Write \(\overline{\Delta_1(T)}\) for the closure of \(\Delta_1(T)\) in \(\mathbb{R}^p\).

**Proposition 4.5.** Let \(a \in \Delta_1(T)\) and \(a' \in \overline{\Delta_1(T)}\). Set \(w = a' - a\). Then \(a + tw \in \Delta_1(T)\) for all \(t \in [0, 1)\). Moreover, there exists \(\alpha \in \mathbb{R}^I\) such that

\[w = \sum_{i \in \mathcal{I}} \alpha_i \Xi_i\]

if and only if

\[\sum_{k \in \mathcal{F}} a_k n_1(k) = \sum_{k \in \mathcal{F}} a'_k n_1(k).\]

Moreover, in this case, \(\alpha\) is uniquely determined by \(w\) and

\[\sum_{i \in \mathcal{I}} |\alpha_i| \leq C_1 \sum_{k \in \mathcal{F}} |a_k - a'_k|\]

for some constant \(C_1 < \infty\) depending only on \(l\).

4.5. Proof of Proposition 2.6. We will show inductively that the following statements hold for all \(n \geq 0\). Firstly, for all combinatorial planar loops \(l\) with no more than \(n\) self-intersections, there is a continuous function

\[\phi_l : \Delta_1(T) \rightarrow \mathbb{R}\]

such that, uniformly on \(\Delta_1(T)\) as \(N \rightarrow \infty\),

\[\phi_l^N \rightarrow \phi_l, \quad \phi_{l,l-1}^N \rightarrow (\phi_l)^2.\]
Secondly, the restriction of the master field $\Phi_T$ to $\text{Loop}_n(S_T)$ is the unique function $\text{Loop}_n(S_T) \to \mathbb{C}$ with the following properties: it is invariant under area-preserving diffeomorphisms, for any combinatorial planar loop $l$ having at most $n$ self-intersections, the quotient map $\phi_l : \Delta_l(T) \to \mathbb{R}$ is uniformly continuous and $\Phi_T$ satisfies the Makeenko–Migdal equations (10) and the estimate (13).

For $a \in \Delta_l(T)$ and $l \in l(a)$,

$$E(|\text{tr}(H_l) - \phi_l(a)|^2) = \phi_{l,1}^N(a) - \phi_l^N(a)^2 + (\phi_l^N(a) - \phi_l(a))^2$$

so the first statement implies that, as $N \to \infty$,

$$\text{tr}(H_l) \to \phi_l(a) = \Phi_T(l)$$

in $L^2$, uniformly in $l \in \text{Loop}_n(S_T)$. So the two statements suffice to prove Proposition 2.6.

For the simple combinatorial loop $s$, set $\phi_s(a, b) = \Phi_T(1, a, b)$ then $\phi_s$ is continuous on $\Delta_s(T)$ and, by Proposition 2.5, $\phi_s^N \to \phi_s$ and $\phi_{s,s-1}^N \to (\phi_s)^2$ uniformly on $\Delta_s(T)$. There are no self-intersections, so no Makeenko–Migdal equations. For $(a, b) \in \Delta_s(T)$ and $s \in s(a, b)$,

$$\Phi_T(s) = \phi_s(a, b) = \Phi_T(1, a, b).$$

Hence the desired statements hold for $n = 0$.

Let $n \geq 1$ and suppose inductively that the desired statements hold for $n - 1$. Let $l$ be a combinatorial planar loop with $n$ self-intersections. Choose faces $k_0$ and $k_\ast$ of minimal and maximal winding number and set

$$n_\ast = n_1(k_\ast) - n_1(k_0).$$

Let $a = (a_1, \ldots, a_{n+2}) \in \Delta_l(T)$. Recall that $a_0, a_\ast \in [0, T]$ are determined by

$$a_0 + a_\ast = T, \quad a_0 n_1(k_0) + a_\ast n_1(k_\ast) = \sum_{k=1}^{n+2} a_k n_1(k). \quad (36)$$

Then, by Proposition 4.5, there exists a unique $\alpha \in \mathbb{R}^I$, with

$$\sum_{i \in I} |\alpha_i| \leq 2C_1(T - a_{k_0} - a_{k_\ast}) \quad (37)$$

such that, for

$$a(t) = a + t \sum_{i \in I} \alpha_i \xi_i$$

we have $a(t) \in \Delta_l(T)$ for all $t \in [0, 1)$ and

$$a_{k_0}(1) = a_0, \quad a_{k_\ast}(1) = a_\ast.$$

By Proposition 4.3, the maps

$$t \mapsto \phi_l^N(a(t)), \quad t \mapsto \phi_{l,1-1}^N(a(t))$$
are differentiable on \([0, 1]\), with
\[
\frac{d}{dt} \phi^N_t(a(t)) = \sum_{i \in I} \alpha_i \phi^N_{i, i_t}(a(t))
\]
and
\[
\frac{d}{dt} \phi^N_{i, i_t-1}(a(t)) = \sum_{i \in I} \alpha_i \left( \phi^N_{i, i_t, i_t-1} + \phi^N_{i_t, i, i_t-1} - N^{-2} (\phi^N_{i_t, i} + \phi^N_{i, i_t}) \right)(a(t)).
\]

Here we have used the fact that the directional derivatives given by Proposition 4.3 are continuous on \(\Delta_1(T)\) to guarantee differentiability in any linear combination of those directions. We integrate to obtain, for all \(t \in [0, 1]\),
\[
\phi^N_t(a(t)) = \phi^N_t(a) + \sum_{i \in I} \int_0^t \alpha_i \phi^N_{i, i_t}(a(s))ds
\]
and
\[
\phi^N_{i, i_t-1}(a(t)) = \phi^N_{i, i_t-1}(a) + \sum_{i \in I} \alpha_i \int_0^t \left( \phi^N_{i, i_t, i_t-1} + \phi^N_{i_t, i, i_t-1} - N^{-2} (\phi^N_{i_t, i} + \phi^N_{i, i_t}) \right)(a(s))ds.
\]

Since \(\phi^N_t\) and \(\phi^N_{i, i_t-1}\) extend continuously to \(\overline{\Delta_1(T)}\) and the integrands on the right are bounded, these equations hold also for \(t = 1\).

We shall now prove the following key identities
\[
\phi^N_t(a(1)) = \phi^N_{g^s_\ast}(a_0, a_\ast), \quad \phi^N_{i, i_t-1}(a(1)) = \phi^N_{g^a_{\ast-\ast}}(a_0, a_\ast).
\]

Choose a loop \(l \in L(a)\) such that the faces \(f_{k_0}\) and \(f_{k_\ast}\) of the associated embedded graph have a \(C^1\) boundary. We will use a deformation \((l_t)_{t \in [0,1]}\) of \(l\) constructed using a diffeomorphism from \(S_T \setminus (f_{k_0} \cup f_{k_\ast})\) to a cylinder and then contracting the cylinder to a circle. Since \(k_\ast\) and \(k_0\) have maximal and minimal winding number, the pair \((a_0, a_\ast)\) defined by (36) satisfies \(a_0 \geq a_{k_0}\) and \(a_\ast \geq a_{k_\ast}\). Hence, there is an area-preserving \(C^1\) diffeomorphism
\[
F : S_T \setminus (f_{k_0} \cup f_{k_\ast}) \to (\mathbb{R}/\mathbb{Z}) \times [-a_0 + a_{k_0}, a_\ast - a_{k_\ast}]
\]
where the right-hand side is endowed with Lebesgue measure. By re-basing the loop \(l\) if necessary, we may assume that the starting point \(l(0)\) is not adjacent to \(f_{k_0}\) or \(f_{k_\ast}\). Write \(F(l(\tau)) = (\theta(\tau), y(\tau))\). We can and do choose \(l\) and \(F\) so that \(F(l(0)) = (0, 0)\) and so that \(\theta(\tau)\) makes only finitely many changes of sign. For \(t \in [0, 1]\) and \((\theta, y) \in (\mathbb{R}/\mathbb{Z}) \times [-a_0 + a_{k_0}, a_\ast - a_{k_\ast}]\), define
\[
C_t(\theta, y) = (\theta, (1 - t)y)
\]
and define a family \((l_t : t \in [0, 1])\) in Loop\((S_T)\) by
\[
l_t(\tau) = F^{-1} \circ C_t \circ F(l(\tau)).
\]
Then \( l_0 = l \) and \((l_t : t \in [0, 1])\) is continuous in length with fixed endpoints. Define
\[
s(\tau) = F^{-1}(\tau, 0).
\]

Then \( s \in \text{Loop}_0(\mathbb{S}_T) \) and, since \( F \circ l_1(\tau) = (\theta(\tau), 0) \), we have \( l_1 \sim s^{n^*} \), where \( n^* = \theta(1) \in \mathbb{Z} \) is the winding number of \( l \). Then, by continuity in probability and invariance under reduction of the holonomy field,
\[
\phi^N_t(a(1)) = \lim_{t \uparrow 1} \phi^N_t(a(t)) = \lim_{t \uparrow 1} \mathbb{E}(\text{tr}(H_t)) = \mathbb{E}(\text{tr}(H_1)) = \mathbb{E}(\text{tr}(H_{s^{n^*}})) = \phi^N_{s^{n^*}}(a_0, a_*).
\]

We see similarly that \( \phi^N_{l_1^{-1}}(a(1)) = \phi^N_{s^{n^*}, s^{-n^*}}(a_0, a_*) \).

Now, given (41), by Proposition 2.5,
\[
\phi^N_{s^{n^*}}(a_1, a_2) \to \phi_T(n_*, a_1, a_2)
\]
uniformly in \((a_1, a_2) \in \Delta_s(T)\). Write \( l_i \) and \( \hat{l}_i \) for the drawings of \( l_i \) and \( \hat{l}_i \) in \( G \) for some \( G \in \mathcal{I}(a) \). Then
\[
\phi^N_{l_i, \hat{l}_i}(a) = \mathbb{E}(\text{tr}(H_{l_i})\text{tr}(H_{\hat{l}_i})).
\]

Since both \( l_i \) and \( \hat{l}_i \) have no more than \( n-1 \) self-intersections, by the inductive hypothesis,
\[
\text{tr}(H_{l_i}) \to \phi_{l_i}(a), \quad \text{tr}(H_{\hat{l}_i}) \to \phi_{\hat{l}_i}(a)
\]
in \( L^2 \), uniformly in \( a \in \Delta_1(T) \). Hence
\[
\phi^N_{l_i, \hat{l}_i} \to \phi_{l_i} \phi_{\hat{l}_i}
\]
uniformly on \( \Delta_1(T) \). Here we used the obvious submersions \( \Delta_1(T) \to \Delta_{l_1}(T) \) and \( \Delta_1(T) \to \Delta_{\hat{l}_i}(T) \) in evaluating \( \phi_{l_i} \) and \( \phi_{\hat{l}_i} \) on \( \Delta_1(T) \). We let \( N \to \infty \) in (39), first in the case \( t = 1 \) and then for \( t \in (0, 1) \) to see that \( \phi^N_t \) converges uniformly on \( \overline{\Delta_1(T)} \) with continuous limit, \( \phi_t \) say, satisfying, for all \( t \in [0, 1] \),
\[
\phi_t(a(t)) = \phi_t(a) + \sum_{i \in \mathcal{I}} \int_0^t a_i \phi_{l_i}(a(s))\phi_{\hat{l}_i}(a(s))ds.
\]

Using again (41) and Proposition 2.5, for \( s \in \mathcal{S}(a_1, a_2) \),
\[
\phi^N_{s^{n^*}, s^{-n^*}}(a_1, a_2) = \mathbb{E}(|\text{tr}(H_{s^{n^*}})|^2) \to \phi_T(n_*, a_1, a_2)^2
\]
uniformly in \((a_1, a_2) \in \Delta_s(T)\) as \( N \to \infty \). We have
\[
\phi^N_{l_i, \hat{l}_i, l_i^{-1}}(a) = \phi^N_{l_i, \hat{l}_i, l_i^{-1}}(a) = \mathbb{E}(\text{tr}(H_{l_i})\text{tr}(H_{\hat{l}_i})\text{tr}(H_{l_i^{-1}}))
\]
and we have just shown that
\[
\mathbb{E}(\text{tr}(H_{l_i^{-1}})) = \mathbb{E}(\text{tr}(H_{l_i})) \to \phi_{l_i}(a)
\]
uniformly in \( a \in \Delta_1(T) \). In combination with (43), we deduce that, uniformly on \( \Delta_1(T) \),
\[
\phi^N_{l, t, l^{-1}} \to \phi_t \phi^*_l \phi_t.
\]
Hence, on letting \( N \to \infty \) in (40), first in the case \( t = 1 \) and then for \( t \in (0, 1) \), we see that \( \phi^N_{1, t, l^{-1}} \) converges uniformly on \( \Delta_1(T) \) with continuous limit, \( \phi_{l, t, l^{-1}} \) say, satisfying, for all \( t \in [0, 1] \),
\[
\phi_{l, 1, l^{-1}}(a(t)) = \phi_{l, 1, l^{-1}}(a) + 2 \sum_{i \in I} \alpha_i \int_0^t \phi_i(a(s))\phi^*_i(a(s))\phi_t(a(s))ds.
\] (45)

By differentiating (44) and (45), we see that
\[
\frac{d}{dt} (\phi_{l, 1, l^{-1}}(a(t)) - \phi_t(a(t))^2) = 0
\]
so
\[
\phi_{l, 1, l^{-1}}(a) - \phi_t(a)^2 = \phi_{l, 1, l^{-1}}(a(1)) - \phi_t(a(1))^2 = 0.
\]
Thus the first of the desired statements holds for \( n \).

We turn to the second statement. First we will show the claimed properties of the master field \( \Phi_T \) on \( \text{Loop}_{n}(S_T) \). By the first statement, for all \( a \in \Delta_1(T) \) and \( l \in l(a) \),
\[
\Phi_T(l) = \phi_t(a).
\]
Hence \( \Phi_T \) is invariant under area-preserving homeomorphisms. We take \( t = 1 \) in (44) and use the estimate (37) to see that
\[
|\Phi_T(l) - \phi_T(n_*, a_0, a_*)| \leq 2C_1(T - a_{k_0} - a_{k_*}).
\]
It remains to show that \( \Phi_T \) satisfies the Makeenko–Migdal equations (10) on \( \text{Loop}_{n}(S_T) \). Let \( l \) be a regular loop with \( n \) self-intersections. Let \( i \in I \) and let \( \theta : [0, \eta) \times S_T \to S_T \) be a Makeenko–Migdal flow at \( (l, v_i) \). Write \( a_\theta(t) \) for the face-area vector of \( l(t) = \theta(t, l) \). Then
\[
a_\theta(t) = a + t\mathbb{E}_i
\]
so, by the argument leading to (44),
\[
\mathbb{E}(\text{tr}(H_{l(t)})) = \mathbb{E}(\text{tr}(H_l)) + \int_0^t \mathbb{E}(\text{tr}(H_{l(s)}))\text{tr}(H_{l_i(s)})ds.
\]
By bounded convergence, on letting \( N \to \infty \), we obtain
\[
\Phi_T(l(t)) = \Phi_T(l) + \int_0^t \Phi_T(l_i(s))\Phi_T(l_i(s))ds
\]
as required.

Suppose finally that \( \Psi : \text{Loop}_{n}(S_T) \to \mathbb{C} \) is another function with the same properties. We have to show that \( \Psi = \Phi_T \) on \( \text{Loop}_{n}(S_T) \). Let \( l \) be a combinatorial planar loop with at most \( n \) self-intersections. Then, for all \( a \in \Delta_1(T) \), the set of embedded loops \( l(a) \) is non-empty, and \( \Psi \) takes a constant value on \( l(a) \). So there is a unique function
\[
\psi_l : \Delta_1(T) \to \mathbb{C}
\]
such that $\psi_1(a) = \Psi(l)$ for all $l \in l(a)$. Let $i$ be a self-intersection of $l$ and let $l \in l(a)$. Then there exists a Makeenko–Migdal flow $\theta$ at $(l, v_i)$. Thus, for $t$ sufficiently small, we have $\theta(t, l) \in l(a + t \mathcal{E}_i)$ and hence

$$\psi_1(a + t \mathcal{E}_i) = \Psi(\theta(t, l)).$$

Since $\Psi$ satisfies the Makeenko–Migdal equations, it follows that $\psi_1$ has a directional derivative at $a$ given by

$$\mathcal{E}_i \psi_1(a) = \frac{d}{dt} \bigg|_{t=0} \Psi(\theta(t, l)) = \psi_1(l_i) \psi_{\hat{l}_i}(a)$$

where $l_i, \hat{l}_i$ are the loops obtained by splitting $l$ at $v_i$, and $l_i, \hat{l}_i$ are the associated combinatorial loops.

Given $a \in \Delta_1(T)$, define $a(t)$ as at (38). Then, by the argument leading to (39), for all $t \in [0, 1)$,

$$\psi_1(a(t)) = \psi_1(a) + \sum_{i \in I} \alpha_i \int_0^t \psi_{l_i}(a(s)) \psi_{\hat{l}_i}(a(s)) ds.$$

Since $\Psi$ satisfies (13), in the limit $t \to 1$, we have

$$|\psi_1(a(t)) - \phi_T(n_s, a_0, a_\ast)| \leq C_n(T - a_{k_0}(t) - a_{k_\ast}(t)) \to 0.$$

By the inductive hypothesis, since $l_i$ and $\hat{l}_i$ have no more that $n - 1$ self-intersections,

$$\psi_{l_i}(a(s)) = \phi_{l_i}(a(s)), \quad \psi_{\hat{l}_i}(a(s)) = \phi_{\hat{l}_i}(a(s))$$

for all $s \in [0, 1)$. Hence $\Psi(l) = \psi_1(a) = \phi_1(a) = \Phi_T(l)$, showing that $\Psi = \Phi_T$ on Loop$_n(S_T)$, as required. Hence both statements hold for $n$ and the induction proceeds.

5. Extension to Loops of Finite Length

5.1. Some estimates for piecewise geodesic loops. Our aim in this section is to prove Proposition 2.7, which is the final step in the proof of our main result Theorem 2.2. We follow a line of argument adapted from [8], where estimates are given for Wilson loops in the plane, which are uniform in $N$. Instead of using explicit formulas for expectations of Wilson loops, the idea is to revisit certain estimates which were used in the construction of the Yang–Mills measure [40, Section 3.3], and to show that, when applied to suitable functions, these estimates are uniform in $N$. For clarity, we shall give a more detailed account of the argument of [8, Theorem 4.1], reproducing part of the proof of [40, Section 3.3].

Write Path$_n(S_T)$ and Loop$_n(S_T)$ for the sets of piecewise geodesic paths and loops in $S_T$. Set $\kappa = \sqrt{\pi T}/2$ and note that $\kappa$ is the length of a great circle between antipodal points in $S_T$. For $\alpha \in \text{Path}(S_T)$, write $n_0(\alpha)$ for the smallest integer such that $2^{-n_0(\alpha)} \ell(\alpha) < \kappa$. For $n \geq n_0(\alpha)$, we define $D_n(\alpha) \in \text{Path}_n(S_T)$ by parametrizing $\alpha$ by $[0, 1]$ at constant speed and then interpolating the points $(\alpha(k2^{-n}) : k = 0, 1, \ldots, 2^n)$ by geodesics. Then $D_n(\alpha) \to \alpha$ in length as $n \to \infty$, so Path$_n(S_T)$ is dense in Path$(S_T)$ for the topology of convergence in length with fixed endpoints. Note in particular that,
when $\ell(\alpha) < \kappa$, we use the notation $D_\alpha(\alpha)$ for the unique geodesic with the same endpoints as $\alpha$. Define, for $\alpha \in \text{Loop}(S_T)$,

$$\Psi_N(\alpha) = \sqrt{E(\text{tr}(I - H_\alpha)))} = \sqrt{1 - \Phi^N_T(\alpha)}, \quad \Phi^N_T(\alpha) = E(\text{tr}(H_\alpha))$$

where $H = (H_\gamma : \gamma \in \text{Path}(S_T))$ is a Yang–Mills holonomy field in $U(N)$. By Lemma 3.5, there is a $K_1 > 0$ such that, for all $N$ and all $a \in [0, T]$, for all simple loops $\alpha$ bounding a domain of area $a$,

$$\Psi_N(\alpha) \leq K_1 \sqrt{a}. \quad (46)$$

The function $\Psi_N$ inherits from $H$ the following properties: for all $\alpha, \beta \in \text{Loop}(S_T)$ with $\alpha \sim \beta$,

$$\Psi_N(\alpha) = \Psi_N(\alpha^{-1}), \quad \Psi_N(\alpha) = \Psi_N(\beta) \quad (47)$$

and, for all pairs of paths $\gamma_1, \gamma_2 \in \text{Path}(S_T)$ which concatenate to form a loop,

$$\Psi_N(\gamma_1 \gamma_2) = \Psi_N(\gamma_2 \gamma_1). \quad (48)$$

Moreover, using the identity

$$2\Psi_N(\alpha \beta)^2 = E\left(\text{tr}((H_\alpha - H^*_\beta)(H^*_\alpha - H_\beta))\right)$$

and Cauchy–Schwarz, we obtain

$$\Psi_N(\alpha \beta) \leq \Psi_N(\alpha) + \Psi_N(\beta) \quad (49)$$

canveraging to zero for a random choice of endpoints. Hence there exists a sequence $(\alpha_k : k \in \mathbb{N})$ in $\text{Loop}_n(S_T)$ such that $\alpha_k \to \alpha$ with fixed endpoints. Since any two distinct segments $\gamma_i$ and $\gamma_j$ either intersect in at most one point, or are contained in the same great circle, the set of loops in this family which are not in $\text{Loop}_n(S_T)$ is of measure zero for a random choice of endpoints. Hence there exists a sequence $(\alpha_k : k \in \mathbb{N})$ in $\text{Loop}_n(S_T)$ such that $\alpha_k \to \alpha$ with fixed endpoints.

Since the set of combinatorial planar loops with $n$ self-intersections is finite, we can assume without loss of generality that there is a combinatorial planar loop $l$ such that $\alpha_k$ is a drawing of $l$ for all $k \geq 1$ and such that $\alpha_l(\alpha_k)$ converges in $\Delta_l(T)$ as $k \to \infty$, with limit $\alpha_l$ say. Consider the Wilson loop function $\phi^N_l : \Delta_l(T) \to \mathbb{C}$. By Proposition 2.6, we know that $\phi^N_l$ is uniformly continuous on $\Delta_l(T)$ for all $N$ and $\phi^N_l \to \phi_l$ uniformly on $\Delta_l(T)$ as $N \to \infty$. Hence $\phi_l$ has a continuous extension to $\Delta_l(T)$, which we denote also by $\phi_l$, and $\phi^N_l \to \phi_l$ uniformly on $\Delta_l(T)$. Now, as $N \to \infty$,

$$\Phi^N_T(\alpha) = \phi^N_l(\alpha) \to \phi_l(\alpha)$$
so we can conclude that the following limit is well-defined

$$\Phi_T(\alpha) = \lim_{N \to \infty} \Phi^N_T(\alpha).$$

Let us set

$$\Psi(\alpha) = \sqrt{1 - \Phi_T(\alpha)}.$$

Then $$\Psi(\alpha) = \lim_{N \to \infty} \Psi^N_N(\alpha)$$ and the properties (46), (47), (48), (49) extend to $$\Psi$$ on taking the limit $$N \to \infty$$. □

We note for later use a further inequality which follows from (47), (48), (49): for all $$\alpha, \beta \in \text{Loop}_*(S_T)$$ having the same base point,

$$|\Psi(\alpha) - \Psi(\beta)| \leq \Psi(\alpha\beta^{-1}).$$ (50)

The following isoperimetric inequality is shown in [40, Lemma 3.3.5]: there is a constant $$K_2 \in [\kappa^{-1}, \infty)$$ such that, for all $$a \in [0, T]$$ and all $$\alpha \in P_*(S_T)$$ of length $$\ell(\alpha) < K_2^{-1}$$ and such that the loop $$s = \alpha^{-1}D_0(\alpha)$$ is simple, we have

$$\sqrt{a} \leq K_2\ell(\alpha)^{3/4}(\ell(\alpha) - \ell(D_0(\alpha)))^{1/4}$$ (51)

where $$a$$ is the smaller of the areas of the connected components of $$S_T \setminus s^*$$. The next proposition follows a line of argument similar to [40, Lemma 3.3.4] but reformulated in a simpler way and taking care to obtain a constant $$K$$ independent of $$N$$.

**Proposition 5.1.** There is a constant $$K \in [\kappa^{-1}, \infty)$$ such that, for all $$N \in \mathbb{N}$$, all $$n \geq 0$$ and all $$\alpha \in \text{Path}(S_T)$$ with $$2^{-n}\ell(\alpha) < K^{-1}$$, we have

$$\Psi_N(\alpha D_n(\alpha)^{-1}) \leq K\ell(\alpha)^{3/4}(\ell(\alpha) - \ell(D_n(\alpha)))^{1/4}.$$

Moreover the same estimate holds for $$\Psi$$ whenever $$\alpha \in \text{Path}_*(S_T)$$.

**Proof.** The argument relies only on the properties (46), (47), (48), (49) which hold for both $$\Psi_N$$ and $$\Psi$$, and the continuity of $$\Psi_N$$ on $$\text{Loop}(S_T)$$, which allows us to reduce to the case $$\alpha \in \text{Path}_*(S_T)$$. We will write it out for $$\Psi$$. Consider first the case where $$\alpha \in \text{Path}_*(S_T)$$, and $$\alpha$$ is injective with $$\ell(\alpha) < \kappa$$. Then (see [40, Proposition 3.3.6] and Fig. 2 therein) we can write $$\alpha$$ as the concatenation $$\alpha_1 \ldots \alpha_p$$ of its excursions away from, or along, $$D_0(\alpha)$$ to obtain a lasso decomposition

$$\alpha D_0(\alpha)^{-1} \sim l_1 \ldots l_p, \quad l_i = \gamma_i s_i \gamma_i^{-1}, \quad s_i = \alpha_i D_0(\alpha_i)^{-1}$$

where $$s_i \in \text{Loop}_*(S_T)$$ and $$\gamma_i \in \text{Path}_*(S_T)$$ for all $$i$$, and where either $$s_i$$ is simple or $$\alpha_i = D_0(\alpha_i)$$, and such that

$$\ell(\alpha) = \ell(\alpha_1) + \cdots + \ell(\alpha_p), \quad \ell(D_0(\alpha)) = \ell(D_0(\alpha_1)) + \cdots + \ell(D_0(\alpha_p)).$$

Write $$a_i$$ for the smaller of the areas of the connected components of $$S_T \setminus s_i^*$$. In the case $$\alpha_i = D_0(\alpha_i)$$, when there is only one such component, set $$a_i = 0$$. Note that
\[ \ell(s_i) \leq 2\ell(\alpha_i) \leq 2\ell(\alpha). \] Take \( K = \max\{K_1 K_2, 2K_2\} \) and suppose that \( \ell(\alpha) < K^{-1}. \) Then

\[
\Psi(\alpha D_0(\alpha)^{-1}) = \Psi(l_1 \ldots l_p) \leq \Psi(l_1) + \cdots + \Psi(l_p) = \Psi(s_1) + \cdots + \Psi(s_p)
\]

\[
\leq K_1(\sqrt{a_1} + \cdots + \sqrt{a_p})
\]

\[
\leq K_1 K_2 \sum_{i} \ell(\alpha_i)^{3/4}(\ell(\alpha_i) - \ell(D_0(\alpha_i)))^{1/4}
\]

\[
\leq K\ell(\alpha)^{3/4}(\ell(\alpha) - \ell(D_0(\alpha)))^{1/4}
\]

where we used Hölder’s inequality for the last step.

Now, for general \( \alpha \in \text{Path}_*(\mathbb{S}_T) \) with \( \ell(\alpha) < K^{-1} \), according to [40, Proposition 1.4.9], we can write \( \alpha \) as a concatenation \( \alpha_1 \ldots \alpha_p \gamma \), where each \( \alpha_i \) is run up to the end of its first interval of self intersection. So we obtain a lasso decomposition

\[
\alpha \sim l_1 \ldots l_p \gamma, \quad l_i = \gamma_i s_i \gamma_i^{-1}, \quad \ell(\alpha) = \ell(s_1) + \cdots + \ell(s_p) + \ell(\gamma)
\]

where \( s_i \in \text{Loop}_*(\mathbb{S}_T) \) is simple and \( \gamma_i \in \text{Path}_*(\mathbb{S}_T) \) for all \( i \), and where \( \gamma \in \text{Path}_*(\mathbb{S}_T) \) is injective. Write \( a_i \) for the smaller of the areas of the connected components of \( \mathbb{S}_T \setminus s_i^* \). Then

\[
\Psi(l_i) = \Psi(s_i) \leq K_1 \sqrt{a_i} \leq K_1 K_2 \ell(s_i)
\]

so

\[
\Psi(l_1) + \cdots + \Psi(l_p) \leq K(\ell(s_1) + \cdots + \ell(s_p)) = K(\ell(\alpha) - \ell(\gamma)).
\]

On the other hand, by the first part,

\[
\Psi(\gamma D_0(\gamma)^{-1}) \leq K\ell(\gamma)^{3/4}(\ell(\gamma) - \ell(D_0(\gamma)))^{1/4}.
\]

But \( D_0(\gamma) = D_0(\alpha) \), so

\[
\Psi(\alpha D_0(\alpha)^{-1}) = \Psi(l_1 \ldots l_p \gamma D_0(\gamma)^{-1}) \leq \Psi(l_1) + \cdots + \Psi(l_p) + \Psi(\gamma D_0(\gamma)^{-1})
\]

\[
\leq K(\ell(\alpha) - \ell(\gamma)) + K\ell(\gamma)^{3/4}(\ell(\gamma) - \ell(D_0(\gamma)))^{1/4}
\]

\[
\leq K\ell(\alpha)^{3/4}(\ell(\alpha) - \ell(D_0(\alpha)))^{1/4}.
\]

Finally, for \( n \geq 0 \) and \( \alpha \in \text{Path}_*(\mathbb{S}_T) \) with \( 2^{-n}\ell(\alpha) < K^{-1} \), we can write \( \alpha \) as a concatenation \( \alpha_1 \ldots \alpha_{2^n} \) such that

\[
D_n(\alpha) = D_0(\alpha_1) \ldots D_0(\alpha_{2^n}), \quad \ell(\alpha_i) = 2^{-n}\ell(\alpha).
\]

Then there is a lasso decomposition

\[
\alpha D_n(\alpha)^{-1} \sim l_1 \ldots l_{2^n}, \quad l_i = \gamma_i \alpha_i D_0(\alpha_i)^{-1} \gamma_i^{-1}
\]

where \( \gamma_i \in \text{Loop}_*(\mathbb{S}_T) \) for all \( i \). Then, by the second part,

\[
\Psi(\alpha D_n(\alpha)^{-1}) = \Psi(l_1 \ldots l_{2^n}) \leq \sum_{i} \Psi(\alpha_i D_0(\alpha_i)^{-1})
\]

\[
\leq \sum_{i} K\ell(\alpha_i)^{3/4}(\ell(\alpha_i) - \ell(D_0(\alpha_i)))^{1/4}
\]

\[
\leq K\ell(\alpha)^{3/4}(\ell(\alpha) - \ell(D_n(\alpha)))^{1/4}.
\]

\[ \square \]
5.2. Proof of Proposition 2.7. Let \((H_\gamma : \gamma \in \text{Path}(S_T))\) be a Yang–Mills holonomy field in \(U(N)\). We have to show that \(\text{tr}(H_l)\) converges in probability as \(N \to \infty\) for all \(l \in \text{Loop}(S_T)\). Further, we have to show that the master field

\[
\Phi_T(l) = \lim_{N \to \infty} \mathbb{E}(\text{tr}(H_l))
\]

is the unique continuous function \(\text{Loop}(S_T) \to \mathbb{C}\) which is invariant under reduction and under area-preserving homeomorphisms, satisfies the Makeenko–Migdal equations (10) on regular loops, and satisfies (11) for simple loops.

Let \(l \in \text{Loop}(S_T)\) and set \(l_n = D_n(l)\). Note that \(D_n(l_m) = l_n\) when \(m \geq n\). By (50) and Proposition 5.1, for \(n \in \mathbb{N}\) sufficiently large and \(m \geq n\),

\[
|\Psi(l_m) - \Psi(l_n)| \leq \Psi(l_m l_n^{-1}) \leq K \ell(l)^{3/4}(\ell(l) - \ell(l_n))^{1/4}.
\]

Also

\[
\mathbb{E}(\|\text{tr}(H_{l_n}) - \text{tr}(H_l)\|^2) \leq \mathbb{E}(\text{tr}((H_{l_n} - H_l)(H_{l_n} - H_l)) = 2\Psi_N(l_n^{-1})^2
\]

so

\[
\|\text{tr}(H_{l_n}) - \text{tr}(H_l)\|_2 \leq \sqrt{2}\Psi_N(l_n^{-1}) \leq \sqrt{2}K \ell(l)^{3/4}(\ell(l) - \ell(l_n))^{1/4}.
\]

Since \(\ell(l_n) \to \ell(l)\) as \(n \to \infty\), we see that \(\Psi(l_n)\) and \(\Phi_T(l_n) = 1 - \Psi(l_n)^2\) must converge as \(n \to \infty\). Define

\[
\tilde{\Phi}(l) = \lim_{n \to \infty} \Phi_T(l_n).
\]

Let \(n \to \infty\) and then \(N \to \infty\) in the inequality

\[
\|\text{tr}(H_l) - \tilde{\Phi}(l)\|_1 \leq \|\text{tr}(H_l) - \text{tr}(H_{l_n})\|_1 + \|\text{tr}(H_{l_n}) - \Phi_T(l_n)\|_1 + \|\Phi_T(l_n) - \tilde{\Phi}(l)\|
\]

to see that \(\text{tr}(H_l) \to \tilde{\Phi}(l)\) in probability and \(\Phi_T(l) = \lim_{N \to \infty} \mathbb{E}(\text{tr}(H_l)) = \tilde{\Phi}(l)\).

The invariance of \(\Phi_T\) on \(\text{Loop}(S_T)\) under reduction and area-preserving homeomorphisms follows from the corresponding invariance properties of \(\Phi_T^N\). The claimed properties of \(\Phi_T\) on simple and regular loops were shown in Propositions 2.5 and 2.6. We now show that \(\Phi_T\) is continuous on \(\text{Loop}(S_T)\). For this, we translate to our context the argument of [40, Proposition 3.3.9]. Let \(\alpha \in \text{Loop}(S_T)\) and let \((\alpha_n : n \in \mathbb{N})\) be a sequence in \(\text{Loop}(S_T)\) which converges to \(\alpha\) in length. We have to show that \(\Phi_T(\alpha_n) \to \Phi_T(\alpha)\).

There exist area-preserving homeomorphisms \(\theta_n\) on \(S_T\) such that \(\theta_n(\alpha_n)\) converges to \(\alpha\) in length with fixed endpoints. We have \(\Phi_T(\alpha) = 1 - \Psi(\alpha)^2\) and we know that \(\Psi(D_m(\alpha_n)) \to \Psi(\alpha_n)\) as \(m \to \infty\). Hence it will suffice to consider the case where \(\alpha_n\) is piecewise geodesic for all \(n\) and \(\alpha_n\) converges to \(\alpha\) in length with fixed endpoints, and to show then that \(\Psi(\alpha_n) \to \Psi(\alpha)\) as \(n \to \infty\). Parametrize \(\alpha\) at constant speed and choose parametrizations for the loops \(\alpha_n\) so that

\[
\|\alpha_n - \alpha\|_\infty = \sup_{t \in [0,1]} |\alpha_n(t) - \alpha(t)| \to 0.
\]

Fix \(m \geq 0\) and write \(D_m(\alpha)\) and \(\alpha_n\) as concatenations

\[
D_m(\alpha) = \sigma_1 \ldots \sigma_{2^m}, \quad \alpha_n = \alpha_{n,1} \ldots \alpha_{n,2^m}
\]
where \( \sigma_i \) is the geodesic from \( \alpha((i - 1)2^{-m}) \) to \( \alpha(2^{-m}) \) and \( \alpha_{n,i} \) is the restriction of \( \alpha_n \) to \( [(i - 1)2^{-m}, i2^{-m}] \). For \( i = 0, 1, \ldots, 2^m \), denote by \( \eta_{n,i} \) the geodesic from \( \alpha(i2^{-m}) \) to \( \alpha_n(i2^{-m}) \). Then \( \ell(\eta_{n,0}) = \ell(\eta_{n,2^m}) = 0 \) and, for \( i = 1, \ldots, 2^m - 1 \),
\[
\ell(\eta_{n,i}) \leq \|\alpha_n - \alpha\|_{\infty}.
\]
Set
\[
\beta_n = \beta_{n,1} \ldots \beta_{n,2^m}, \quad \beta_{n,i} = \eta_{n,i-1}\alpha_{n,i} \eta_{n,i}^{-1}.
\]
Then \( \alpha_n \sim \beta_n \) and \( D_0(\beta_{n,i}) = \sigma_i \) for all \( i \). So
\[
\Psi(\alpha_n D_m(\alpha)^{-1}) = \Psi(\beta_n D_m(\alpha)^{-1})
\]
and, by the argument used in the last part of the proof of Proposition 5.1,
\[
\Psi(\beta_n D_m(\alpha)^{-1}) \leq K \ell(\beta_n)^{3/4}(\ell(\beta_n) - \ell(D_m(\alpha))^{1/4}.
\]
Now
\[
\ell(\beta_n) \leq \ell(\alpha_n) + 2^{m+1}\|\alpha_n - \alpha\|_{\infty}
\]
so
\[
|\Psi(\alpha_n) - \Psi(\alpha)| \leq \Psi(\alpha_n D_m(\alpha)^{-1}) + |\Psi(D_m(\alpha)) - \Psi(\alpha)|
\leq K(\ell(\alpha_n) + 2^{m+1}\|\alpha_n - \alpha\|_{\infty})^{3/4}(\ell(\alpha_n) - \ell(D_m(\alpha)) + 2^{m+1}\|\alpha_n - \alpha\|_{\infty})^{1/4} + |\Psi(D_m(\alpha)) - \Psi(\alpha)|.
\]
On letting first \( n \to \infty \) and then \( m \to \infty \), we see that \( \Psi(\alpha_n) \to \Psi(\alpha) \) as required.

Finally, suppose that \( \Psi : \text{Loop}(\mathbb{S}_T) \to \mathbb{C} \) is another function with the same properties. Then \( \Psi = \Phi_T \) on \( \text{Loop}_0(\mathbb{S}_T) \). Suppose inductively for \( n \geq 1 \), that \( \Psi = \Phi_T \) on \( \text{Loop}_{n-1}(\mathbb{S}_T) \), and let \( \ell \in \text{Loop}_n(\mathbb{S}_T) \). We follow the argument at the end of the proof of Proposition 2.6, except that, in place of the estimate (13), we use the cylinder-based loop deformation \( l_i \) defined at (42) and the continuity of \( \Psi \) to see that
\[
\psi_1(a(t)) = \Psi(l_1) \to \Psi(l_1) = \Psi(s^{n*}) = \Phi_T(n_*, a_0, a_*).
\]
Then we can conclude as before that \( \Psi = \Phi_T \) on \( \text{Loop}_n(\mathbb{S}_T) \). Hence, by induction, \( \Psi = \Phi_T \) on all regular loops. But these are dense in \( \text{Loop}(\mathbb{S}_T) \) and \( \Psi \) and \( \Phi_T \) are continuous, so \( \Psi = \Phi_T \) on \( \text{Loop}(\mathbb{S}_T) \).

6. Further Properties of the Master Field

6.1. Relation with the Hermitian Brownian loop. Let \( W = (W_t : t \geq 0) \) be a Brownian motion in the set of \( N \times N \) Hermitian matrices \( H(N) \) equipped with the inner product
\[
\langle h_1, h_2 \rangle = N \text{Tr}(h_1 h_2^*).
\]
Let \( w = (w_t : t \geq 0) \) be a free Brownian motion, defined on some non-commutative probability space \((\mathcal{A}, \tau)\). The inner product is scaled with \( N \) so that \( W \) converges in non-commutative distribution (in probability) to \( w \), that is to say, for all \( n \in \mathbb{N} \) and all \( t_1, \ldots, t_n \geq 0 \),
\[
\text{tr}(W_{t_1} \ldots W_{t_n}) \to \tau(w_{t_1} \ldots w_{t_n})
\]
in probability as $N \to \infty$. Fix $T \in (0, \infty)$ and define for $t \in [0, T]$

$$B_t = W_t - \frac{i}{T} W_T, \quad b^T_t = w_t - \frac{i}{T} w_T.$$  

Then $B = (B_t : t \in [0, T])$ is a Hermitian Brownian loop in $H(N)$ and $B$ converges in non-commutative distribution to $b^T = (b^T_t : t \in [0, T])$. The non-commutative process $b^T$ is called the free Hermitian Brownian loop. We will write simply $b$ for $b^T$.

Let $x = (x_t : t \in [0, T])$ be a free unitary Brownian loop in $(A, \tau)$, as defined in Sect. 2.7.

**Proposition 6.1.** Suppose that $T \in (0, \pi^2]$. Then, for all $t \in [0, T]$ and all $n \in \mathbb{Z}$,

$$\tau(x^n_t) = \int_{\mathbb{R}} e^{inx} s_{\sqrt{T(T-t)/T}}(x) dx = \tau(e^{ib^T_t})$$

where $s_t$ is the semi-circle density (15) of variance $t$. On the other hand, for almost all $T$ and almost all $s, t \in (0, T)$ with $s < t$,

$$\tau(x^*_s x_t) \neq \tau(e^{-ib^T_s} e^{ib^T_t})$$

so $(e^{ib^T_t} : t \in [0, T])$ is not a free unitary Brownian loop.

**Proof.** The first assertion is the content of Proposition 3.6. We turn to the second assertion. Let $(X_t : t \in [0, T])$ be a Brownian loop in $U(N)$ based at 1. Then, since Brownian motion in $U(N)$ is a Lévy process, $X^{-1}_s X_t$ has same law as $X_{t-s}$. On letting $N \to \infty$, we deduce that

$$\tau(x^*_s x_t) = \tau(x_{t-s}) = \tau(e^{ib^T_{t-s}}) = \tau(e^{i(b^T_t - b^T_s)})$$

where we used free independence and stationarity of the increments of free Brownian motion for the last equality. Hence, by the scaling properties of free Brownian motion,

$$\tau(e^{-ib^T_s} e^{ib^T_t} - \tau(x^*_s x_t)) = \tau(e^{-ib^T_s} e^{ib^T_t} - e^{i(b^T_t - b^T_s)}) = F_{s,t}(\sigma)$$

where

$$F_{s,t}(\sigma) = \tau(e^{-i\sigma b_s} e^{i\sigma b_t} - e^{i\sigma(b_s - b_t)}).$$

By Fubini’s theorem, it will suffice to show, for all $s, t \in (0, 1)$ with $s < t$, that $F_{s,t}(\sigma) \neq 0$ for almost all $\sigma \in (0, \pi]$. We expand the exponential function up to fourth order and use scale invariance of free Brownian motion to obtain

$$F_{s,t}(0) = F_{s,t}'(0) = F_{s,t}''(0) = F_{s,t}'''(0) = 0, \quad F_{s,t}^{iv}(0) = 2\tau(b^2_s b^2_t - b_s b_t b_s b_t).$$

The variables $(b_t : t \in [0, 1])$ are semi-circular, therefore all free cumulants of order more than 3 vanish (see for example [46, equation 11.4]). So, using the decomposition of moments into free cumulants $^6$ (see [46, equation 11.8]),

$$\tau(b^2_s b^2_t - b_s b_t b_s b_t) = \tau(b^2_s) \tau(b^2_t) - \tau(b_s b_t)^2 = s(t - s)(1 - t) > 0.$$

Since $F_{s,t}$ is analytic in $\sigma$ on $(0, \pi]$, this implies that it has at most finitely many zeros. \hfill \Box

---

$^6$ Here it can be understood as a ‘non-commutative’ Wick formula, with non-crossing matchings in place of all matchings.
6.2. Duality at the midpoint of the loop. Recall from (6) and (8) the form of $\rho_T$. It will be convenient to set $\alpha = 0$ and $\beta = 2/\sqrt{T}$ in the subcritical case $T \in (0, \pi^2]$. Denote by $\mathbb{H}$ the open upper half-plane. The following relation appeared first in the physics literature [28, equation 1.2], without a mathematical proof.

**Proposition 6.2.** Let $(x_t : t \in [0, T])$ be a free unitary Brownian loop. Then, for all $T > 0$, the spectral measure of $x_{T/2}$ has a density $\rho_T^*$ with respect to Lebesgue measure on $U$ (of mass $2\pi$), which is invariant under complex conjugation and is such that

$$\pi \rho_T^* : U \cap \mathbb{H} \to (\alpha, \beta)$$

is the inverse mapping of

$$e^{i\pi \rho_T} : (\alpha, \beta) \to U \cap \mathbb{H}.$$

**Proof.** We write the proof for the supercritical case $T > \pi^2$, leaving the minor adjustments needed when $T \leq \pi^2$ to the reader. The function $\rho_T : (\alpha, \beta) \to (0, 1)$ is continuous and strictly decreasing, with $\rho_T(\alpha) = 1$ and $\rho_T(\beta) = 0$. Indeed, according to formula (8) and an elementary computation (see for example [44, equation 150]), for $x \in (\alpha, \beta)$,

$$\frac{\pi \alpha}{2} \sqrt{(x^2 - \alpha^2)(\beta^2 - x^2)} \rho_T'(x) = \int_0^1 \frac{\alpha^2 s^2 - x^2}{\beta^2 \sqrt{(1 - s)(1 - k^2 s^2)}} ds < 0.$$

Write $\psi$ for the inverse of the bijection $\pi \rho_T : (\alpha, \beta) \to (0, \pi)$. For all $n \in \mathbb{Z}\{0\}$, by Lemma 3.7,

$$\tau(x_{T/2}^n) = \frac{2}{n\pi} \int_{\alpha}^{\beta} \sin(n\pi \rho_T(x)) dx = -\frac{2}{n\pi} \int_0^{\pi} \sin(n\theta) \psi'(\theta) d\theta.$$

We integrate by parts to obtain

$$\tau(x_{T/2}^n) = \frac{2}{\pi} \int_0^{\pi} \cos(n\theta) \psi(\theta) d\theta.$$

Hence the spectral measure of $x_{T/2}$ has a density $\rho_T^*$ with respect to Lebesgue measure on $U$ given by

$$\rho_T^*(e^{i\theta}) = \psi(|\theta|)/\pi, \quad |\theta| \leq \pi.$$

\[\square\]

6.3. Convergence to the planar master field. We now investigate the behaviour of the master field $\Phi_T$ as $T \to \infty$. For $T > 0$, $n \in \mathbb{N}$ and $t \in [0, T]$, set

$$m_T(n, t) = \Phi_T(l^n)$$

where $l$ is a simple loop which divides $S_T$ into components of areas $t$ and $T - t$. Recall that $m_T(n, t)$ does not depend on the choice of $l$. 

A. Dahlqvist, J. R. Norris
Proposition 6.3. We have

\[ m_T(n, t) \to \frac{e^{-nt/2}}{2\pi in} \int_{\gamma} \left(1 + \frac{1}{z}\right)^n e^{-ntz} \, dz = e^{-nt/2} \sum_{k=1}^{n-1} \frac{(-t)^k}{k!} \left(\frac{n}{k+1}\right) n^{k-1} \]

uniformly in \( t \in [0, T] \) as \( T \to \infty \), where \( \gamma \) is any positively oriented loop in \( \mathbb{C} \) winding once around 0.

Proof. Since the second complete elliptic integral \( E(k) \) is bounded and the first \( K(k) \) is bounded on compacts in \([0, 1)\), the relation

\[ T = 8E K - 4(1 - k^2) K^2 \]

forces \( k \to 1 \) as \( T \to \infty \). Since \( \alpha = k\beta \leq 1/2 \) and \( \beta \geq 1/2 \) for all \( T \), this implies \( \alpha, \beta \to 1/2 \) as \( T \to \infty \). Hence \( \rho_T(x) \to 1 \) for \( |x| < 1/2 \) and \( \rho_T(x) \to 0 \) for \( |x| > 1/2 \), so

\[ G_T(z) = \int_{\mathbb{R}} \frac{\rho_T(x)}{z - x} \, dx \to \int_{-1/2}^{1/2} \frac{dx}{z - x} = \log \left(\frac{z + 1/2}{z - 1/2}\right) \]

uniformly on compacts in \( \{z \in \mathbb{C} : |z| > 1/2\} \). By Proposition 3.7, for \( R > 1/2 \) and \( T \) sufficiently large, uniformly in \( t \in [0, T] \),

\[ m_T(n, t) = \frac{1}{2\pi in} \int_{\gamma_R} \exp\left(-n(tz - G_T(z))\right) \, dz \to \frac{1}{2\pi in} \int_{\gamma_R} e^{-ntz} \left(\frac{z + 1/2}{z - 1/2}\right)^n \, dz = e^{-nt/2} \int_{\gamma} \left(1 + \frac{1}{z}\right)^n e^{-ntz} \, dz \]

where \( \gamma_R \) is the positively oriented boundary of \( \{z \in \mathbb{C} : |z| = R\} \). □

We remark that it is known from Biane [4] that the free unitary Brownian motion has spectral measure \( \nu_t \) on the circle \( \mathbb{U} \), with moments given for all \( n \in \mathbb{Z} \), by

\[ \int_\mathbb{U} \omega^n \nu_t(d\omega) = e^{-|n|t/2} \sum_{k=1}^{\infty} \frac{(-t)^k}{k!} \left(\frac{|n|}{k+1}\right)|n|^{k-1} \]

whereas the spectral measure \( \nu_t^N \) of a Brownian motion on \( U(N) \) at time \( t \) satisfies

\[ \nu_t^N \rightharpoonup \nu_t \]

weakly in probability on \( \mathbb{U} \) as \( N \to \infty \). See also Lévy [39], for another proof using Schur–Weyl duality. Let us write \( \nu_{t,T}^N \) and \( \nu_{t,T} \) for the spectral measure of a marginal of respectively the unitary Brownian loop on \( U(N) \) and of the free unitary Brownian loop (defined in Sect. 2.7), where both processes have lifetime \( T \) and the marginal is taken at time \( t \). We can now deduce that the following diagram commutes

\[ \begin{array}{ccc}
\nu_{t,T}^N & \xrightarrow{N \to \infty} & \nu_{t,T} \\
\downarrow & & \downarrow \\
\nu_t^N & \xrightarrow{N \to \infty} & \nu_t
\end{array} \]
where the horizontal arrows denote weak limits on $\mathbb{U}$ as $N \to \infty$, which follow from Theorem 2.9 and Corollary 2.8, along with [4], whereas the left vertical arrow denotes a limit in law on $\mathcal{M}_1(\mathbb{U})$ and the right vertical arrow denotes the weak limit induced by Proposition 6.3. The next proposition enables us to show that such a commutative diagram holds true for the non-commutative distributions. We will not give details here on this latter point.

Denote by $\text{Loop}(\mathbb{R}^2)$ the set of loops of finite length in $\mathbb{R}^2$ and let

$$
\Phi : \text{Loop}(\mathbb{R}^2) \to [-1, 1]
$$

be the planar master field as defined in [41].

**Proposition 6.4.** For each $T > 0$, fix a point $y_T \in S_T$ and denote by $p_T$ the inverse map of the stereographic projection $S_T \setminus \{y_T\} \to \mathbb{C}$. Then, for all $l \in \text{Loop}(\mathbb{R}^2)$,

$$
\Phi_T(p_T(l)) \to \Phi(l) \quad \text{as} \quad T \to \infty.
$$

**Proof.** Let $l$ be a simple loop in $\text{Loop}(\mathbb{R}^2)$ and denote by $a$ the finite area enclosed by $l$. Then $p_T(l)$ is a simple loop in $\text{Loop}(S_T)$ which divides $S_T$ into two components and does not pass through $y_T$. Denote by $a_T$ the area of the component which does not contain $y_T$. Then $a_T \to a$ as $T \to \infty$. By Proposition 6.3, this implies

$$
\Phi_T(p_T(l^n)) = e^{-na/2} \sum_{k=1}^{n-1} \frac{(-a)^k}{k!} \left( \begin{array}{c} n \\ k+1 \end{array} \right) n^{k-1} = \Phi(l^n)
$$

as $T \to \infty$, where we used [41, equation (2)] for the last equality.

Now $\Phi$ also satisfies the Makeenko–Migdal equations [41]. By a variation of the argument used to prove Theorem 2.6, we can extend convergence from powers of simple loops to all regular loops. We sketch the small change which is needed. There is now a face, $k_\infty$ say, of infinite area. So we work in the orthant $Y_l = \{(a_k : k \in \mathcal{F}_l) : a_{k_\infty} = \infty \text{ and } a_k \in (0, \infty) \text{ for all } k \neq k_\infty\}$. Set

$$
\bar{a} = \sum_{k \neq k_\infty} a_k.
$$

Write $k_0, k_*$, as before, for the faces of minimal and maximal winding number, now choosing the additive constant so that $n_1(k_\infty) = 0$. Given $a \in Y_l$, either $\langle a, n_1 \rangle \geq 0$, or $\langle a, n_1 \rangle < 0$. (We use here the convention that $\infty \times 0 = 0$.) In the first case, $k_* \neq k_\infty$ and there exists $a' \in \overline{Y}_l$ with $a'_k = 0$ for $k \neq k_*, k_\infty$ such that

$$
\langle a', n_1 \rangle = a'_* n_1(k_*) = \langle a, n_1 \rangle.
$$

Set

$$
v_k = \begin{cases} 
    a'_k - a_k, & \text{if } k \neq k_\infty, \\
    \bar{a} - a', & \text{if } k = k_\infty.
\end{cases}
$$

and set $a(t) = a + tv$. Then $a' = a(1)$ and $a(t) \in Y_l$ for all $t \in [0, 1)$, and $v \in m_l$ by Proposition 4.5. An analogous argument holds in the second case. We can then proceed as in Sect. 4.5. The arguments of Sect. 5 also carry over to extend the limit

$$
\Phi_T(p_T(l)) \to \Phi(l)
$$

to all $l \in \text{Loop}(\mathbb{R}^2)$. We omit the details.  

\[\square\]
6.4. Uniqueness of the master field. In Theorem 2.4, we showed that the master field is characterized by certain properties. In fact there is some redundancy in this characterization, as the following result shows in replacing property (11) by (52), which is the case \( n = 1 \) of (11).

**Proposition 6.5.** Let \( \Phi : \text{Loop}(S_T) \to \mathbb{C} \) be a continuous function, which is invariant under reduction and under area-preserving, orientation-preserving homeomorphisms, satisfies the Makeenko–Migdal equations on regular loops, and is given on simple loops \( l \) by

\[
\Phi(l) = \frac{2}{\pi} \int_0^\infty \cosh \left\{ (a - b)x/2 \right\} \sin \left\{ \pi \rho_T(x) \right\} dx
\]

(52)

where \( a \) and \( b \) are the areas of the connected components of \( S_T \setminus \{ l^* \} \). Then \( \Phi \) is the master field \( \Phi_T \).

Furthermore, we shall see in the next section that given the value (52) of \( \Phi_T(l) \) for any simple loops, it is possible to obtain new explicit formulas for \( \Phi_T(l^m) \) using the Makeenko-Migdal equations (see (55)), matching with (11). The proof of proposition 6.5 will be based on an argument for a special class of loops which we now introduce.

Informally, for \( n \geq 1 \) fix an initial point \( x_1 \) and draw an inward anticlockwise spiral which winds \( n \) times around another point \( o \), crossing the line \( ox_1 \) at points \( x_2, \ldots, x_n \) then, on hitting \( ox_1 \) for the \( n \)th time, returning to \( x_1 \) along \( ox_1 \). Thus we obtain a combinatorial planar loop \( l_n \) whose combinatorial graph is given as follows:

\[ \mathcal{V} = \{ 1, \ldots, n \}, \quad \mathcal{E} = \{ 1, \ldots, n \} \cup \{ 1', \ldots, (n - 1)' \}, \quad \mathcal{F} = \{ 0, 1, \ldots, n \} \]

where, for \( j = 1, \ldots, n - 1 \),

\[ s(j) = j, \quad t(j) = j + 1, \quad s(j') = j + 1, \quad t(j') = j \]

and

\[ l(j) = l(j') = j, \quad r(j) = r(j') = j - 1 \]

while

\[ s(n) = t(n) = n, \quad l(n) = n, \quad r(n) = n - 1. \]

See Fig. 6. Here, we have used a non-standard labelling for the edges and faces which is adapted to the structure of the graph. Note that the self-intersections of \( l_n \) are labelled by \( \{ 2, \ldots, n \} \). If we fix the additive constant for the winding number so that \( n_{l_n}(0) = 0 \), then \( n_{l_n}(n) = n \). For \( n \geq 1 \) and for any combinatorial planar loop \( l \) with \( n - 1 \) self-intersections, we have

\[ n_* = \max\{ n_1(k) - n_1(k') : k, k' \in \mathcal{F} \} \leq n. \]

We call \( l_n \), and any associated regular embedded loop \( l \), and any rerooting of \( l \), a maximally winding loop.

**Proof of Proposition 6.5.** Let \( n \geq 1 \) and suppose inductively that \( \Phi(l^m) = \Phi_T(l^m) \) for all \( m \leq n \) and all simple loops \( l \). A comparison of equations (11) and (52) shows that this is true for \( n = 1 \). Let \( l \) be a simple loop which divides \( S_T \) into components of areas \( a_0, a_* \in (0, T) \). We can find \( (\alpha_1, \alpha_2, \ldots, \alpha_{n+2}) \) such that

\[ \alpha_1 = 0, \quad \alpha_2 = a_0, \quad \alpha_{n+1} = a_*, \quad \alpha_{n+2} = 0 \]
and, for \( m = 2, \ldots, n + 1 \),
\[
\alpha_{m-1} - 2\alpha_m + \alpha_{m+1} < 0.
\]
Consider the (constant) vector field \( v \) on \( \Delta_{n+1}(T) \) given by
\[
v = \sum_{i=2}^{n+1} \alpha_i \Xi_i.
\]
Then \( v_0 = -a_0 \) and \( v_{n+1} = -a_* \) and \( v_k > 0 \) for \( k = 1, \ldots, n \). Set
\[
a(t) = (a_0, 0, \ldots, 0, a_*) + tv
\]
then \( a(t) \in \Delta_{n+1}(T) \) for all \( t \in (0, 1) \) and \( a_0(1) = a_{n+1}(1) = 0 \). There exists a continuous family of loops \( (l(t) : t \in [0, 1]) \), with a common basepoint such that, \( l(0) = l^{n+1}, l(t) \in G_{n+1}(a(t)) \) for all \( t \in (0, 1) \), and \( l(1) \) is a maximally winding loop with \( n-2 \) self-intersections. Then, by the arguments used in the proof of Proposition 2.6,
\[
\Phi(l(1)) = \Phi(l^{n+1}) + \sum_{i=2}^{n+1} \alpha_i \int_0^1 \Phi(l_i(s))\Phi(\hat{l}_i(s))ds
\]
where \( l_i(s) \) and \( \hat{l}_i(s) \) are maximally winding loops having \( i-2 \) and \( n+1-i \) self-intersections. But the same equation holds for \( \Phi_T \) and the inductive hypothesis, combined with the argument of the proof of Proposition 2.6, implies that
\[
\Phi(l(1)) = \Phi_T(l(1)), \quad \Phi(l_i(s)) = \Phi_T(l_i(s)), \quad \Phi(\hat{l}_i(s)) = \Phi_T(\hat{l}_i(s)).
\]
Hence \( \Phi(l^{n+1}) = \Phi_T(l^{n+1}) \) and the induction proceeds. Finally, by Proposition 2.6, it follows that \( \Phi(l) = \Phi_T(l) \) for all \( l \in \text{Loop}(\mathbb{S}_T) \). □
On the other hand, condition (52) is not redundant in Proposition 6.5, as we now show. Each loop \( l \in \text{Loop}(S_T) \) has a winding number function

\[ n_l : S_T \setminus l^\# \to \mathbb{Z} \]

which is unique up to an additive constant. By the Banchoff–Pohl inequality [2], we know that \( n_l \in L^2(S_T) \) so \( n_l \) has a well-defined average value \( \langle n_l \rangle \) with respect to the uniform distribution on \( S_T \), up to the same additive constant. Hence, we can define a unique function \( \Psi : \text{Loop}(S_T) \to \mathbb{C} \) by

\[ \Psi(l) = e^{2\pi i \langle n_l \rangle}. \]

For loops \( l_1, l_2 \) based at the same point, we have \( n_{l_1 l_2} = n_{l_1} + n_{l_2} \), so

\[ \Psi(l_1 l_2) = \Psi(l_1) \Psi(l_2). \]

Moreover, \( \Psi \) is invariant under any Makeenko–Migdal flow. Consider, for \( n \in \mathbb{Z} \), the twisted master field \( \Phi_T^{(n)} : \text{Loop}(S_T) \to \mathbb{C} \) given by

\[ \Phi_T^{(n)}(l) = \Psi(l)^n \Phi_T(l). \]

Then \( \Phi_T^{(n)} \) is continuous, invariant under reduction and area-preserving, orientation-preserving homeomorphisms and satisfies the Makeenko–Migdal equations on regular loops. However, for a simple loop \( l \) which winds positively around a domain of area \( a \), we have

\[ \Psi(l) = e^{2\pi i a / T} \]

so, for \( n \neq 0 \), \( \Phi_T^{(n)} \) is not the master field. Hence, by Proposition 6.5, or by inspection, \( \Phi_T^{(n)} \) does not satisfy (52).

For \( n \neq 0 \), the twisted field \( \Phi_T^{(n)} \) from the preceding paragraph also fails to be invariant under orientation-reversing homeomorphisms. We do not know whether this stronger invariance condition would allow one to dispense with (52) in Proposition 6.5.

6.5. Combinatorial formulas for the master field. Rusakov [47] proposed, without proof, that there should be a closed formula for the value of the master field for any regular loop on the sphere. We now prove a formula for a restricted class of loops introduced in [34], which agrees with (42) in [47]. We were not able to prove or disprove this latter formula in the general case \(^7\) and leave this question open. Let us say that a combinatorial planar loop \( l \) is splittable \(^8\) if for all self-intersection points \( i \) of \( l \), the two loops \( l_i, \hat{l}_i \), obtained by following outgoing strands of \( l \) starting from \( i \), intersect only at \( i \) (Fig. 7).

Let \( l \) be a splittable combinatorial planar loop with \( n \) points of intersection. On splitting \( l \) at all points of intersection, we obtain a family of simple combinatorial loops \( S_l = \{ s_1, \ldots, s_{n+1} \} \) in \( l \), which has the structure of a tree, in which \( s_j \) and \( s_{j'} \) are adjacent if they share a point of intersection of \( l \). We choose the sequence \( (s_1, \ldots, s_{n+1}) \) to be an

---

\(^7\) Note that, contrary to what it is claimed in [47], \( n_{i,j} \) can be even or odd.

\(^8\) In [34] these loops are called planar. A loop is splittable if and only if, with notations from [47], \( n_{i,j} = 1 \) for all window’s labels \( i, j \).
Fig. 7. A splittable combinatorial planar loop with its family of simple loops $S_l$ drawn in dashed lines, next to a combinatorial representation of the tree structure of $S_l$

adapted labelling of $S_l$, meaning that $s_{k+1}$ is adjacent to at least one of $s_1, \ldots, s_k$ for all $k \in \{1, \ldots, n\}$. Given $T \in (0, \infty)$, a distinguished face $k \in F_l$ and an adapted labelling $(s_1, \ldots, s_{n+1})$ of $S_l$, let us say that a sequence $(\gamma_1, \ldots, \gamma_{n+1})$ of disjoint simple loops in $C$ around $[-\beta, \beta]$ is admissible if

(a) $\gamma_{j+1}$ lies in the infinite component of $C \setminus \gamma^*$ for all $j \leq n$,
(b) $\gamma_j$ has the same orientation in $C$ as $s_j$ has around $k$ for all $j$.

For any self-intersection point $i$ of $l$, we label the loops among $l_i, \hat{l}_i$ using the left and right outgoing edges at $i$ by $l_{i,l}$ and $l_{i,r}$ respectively. The loops $l_{i,l}$ and $l_{i,r}$ are also splittable, and the pair $\{S_{l_{i,l}}, S_{l_{i,r}}\}$ is a partition of $S_l$. Write $j(i, l)$ and $j(i, r)$ for the loop labels in $S_l$ such that $s_{j(i, l)}$ and $s_{j(i, r)}$ use the left and right outgoing edges at $i$ respectively. Let $n_l$ be the winding number function of $l$, where the additive constant is chosen so that $n_l(k) = 0$. Set $\varepsilon_j = -1$ or $\varepsilon_j = 1$ according as $s_j$ winds positively or negatively around $k$. Set

$$O_l = \{(z_1, \ldots, z_{n+1}) \in \mathbb{C}^{n+1} : z_j \neq z_{j'} \text{ for all } j, j' \text{ distinct}\}$$

and, for $a \in \Delta_l(T)$ and $z \in O_l$, define

$$Q_{l,k}(a, z) = \frac{\prod_{j=1}^{n+1} \exp(\langle n_t, a \rangle z_j + \varepsilon_j G_T(z_j))}{\prod_{i \in I}(z_{j(i,r)} - z_{j(i,l)})},$$

where $I$ denotes, as in Sect. 4.1, the set of points of intersection of $l$. Recall from Sect. 4.5 that, for all combinatorial planar loops $l$, there is a uniformly continuous map

$$\phi_l : \Delta_l(T) \to \mathbb{R}$$

such that $\Phi_T(l) = \phi_l(a)$ for all $a \in \Delta_l(T)$ and all $l \in l(a)$. 
Proposition 6.6. For all \( T \in (0, \infty) \), all splittable combinatorial planar loops \( l \) with \( n \) self-intersections and equipped with a distinguished face \( k \), all adapted labellings \( (s_1, \ldots, s_{n+1}) \) of \( S_1 \), and all admissible sequences of closed loops \( (\gamma_1, \ldots, \gamma_{n+1}) \), we have, for all \( a \in \Delta_1(T) \),
\[
\phi_1(a) = \left( \frac{1}{2\pi i} \right)^{n+1} \int_{\gamma_1} dz_1 \cdots \int_{\gamma_{n+1}} dz_{n+1} \prod_{j=1}^{n+1} \frac{\exp(\langle n_1, a \rangle z_j + \epsilon_j G_T(z_j))}{(z_1 - z_2)(z_2 - z_3) \cdots (z_{n-1} - z_n)}.
\]

Before proving this proposition, let us give an example with maximally winding loops, as defined in Sect. 6.4. Any maximally winding loop \( l_n \), with \( n \geq 1 \) is splittable. According to proposition 6.6, using the labelling of Sect., 6 as in Fig. 6 and choosing 0 as the distinguished face, for any \( (a_0, \ldots, a_n) \in \Delta_{l_n}(T) \),
\[
\phi_n(a_0, a_1, \ldots, a_n) = \left( \frac{1}{2\pi i} \right)^n \int_{\gamma_1} dz_1 \cdots \int_{\gamma_n} dz_n \prod_{j=1}^{n} \frac{\exp(\langle \sum_{i=j}^{n} a_i \rangle z_j - G_T(z_j))}{(z_1 - z_2)(z_2 - z_3) \cdots (z_{n-1} - z_n)}
\]

where \( (\gamma_1, \ldots, \gamma_n) \) are nested clockwise-oriented simple loops in \( \mathbb{C} \) around \([-\beta, \beta]\) and \( g_{j+1} \) lies in the infinite component of \( \mathbb{C} \setminus \gamma_j^* \) for all \( j \leq n - 1 \). Recall that if \( l \) is a simple loop which divides \( S_T \) into components of areas \( a \) and \( b \), then \( \Phi_T(l^n) = \phi_{l_n}(a, 0, \ldots, 0, b) \). Therefore, for such a simple loop \( l \), the last formula yields the identity
\[
\Phi_1(l^n) = \left( \frac{1}{2\pi i} \right)^n \int_{\gamma_1} dz_1 \cdots \int_{\gamma_n} dz_n \prod_{j=1}^{n} \frac{\exp(b z_i - G_T(z_j))}{(z_1 - z_2)(z_2 - z_3) \cdots (z_{n-1} - z_n)}.
\]

Thanks to the following lemma and proposition 3.7, this new formula agree the first formula we obtained (11).

Lemma 6.7. For \( n \geq 2 \) and \( F : (\mathbb{C} \setminus [-\beta, \beta])^n \to \mathbb{C} \) a holomorphic symmetric function,
\[
\left( \frac{1}{2\pi i} \right)^n \int_{\gamma_1} dz_1 \cdots \int_{\gamma_n} dz_n \frac{F(z_1, \ldots, z_n)}{(z_1 - z_2)(z_2 - z_3) \cdots (z_{n-1} - z_n)}
= \frac{1}{2i\pi n} \int_{\gamma_1} F(z, \ldots, z) dz
\]

where \( (\gamma_1, \ldots, \gamma_n) \) are nested contours as in (54).

Proof. For \( n = 2 \), the formula follows from the residue theorem. The result can then be proved by induction on \( n \), using the identity
\[
\sum_{m=0}^{n-1} \frac{1}{\prod_{k=1}^{n-1}(z_{\sigma^m(k)} - z_{\sigma^m(k+1)})} = 0
\]

where \( \sigma \) is the full cycle \((1 2 \ldots n)\), changing variables, using the residue theorem and lastly the induction hypothesis. The details are left to the reader. \( \square \)

To prove Proposition 6.6, we will need the following technical lemma. Set
\[
\Delta_{l, \mathbb{C}}(T) = \left\{ (a_k : k \in \mathcal{F}_l) : a_k \in \mathbb{C}, \sum_k a_k = T \right\}.
\]
Lemma 6.8. The map $\phi_1$ has an analytic extension $\Delta_{1,\mathbb{C}}(T) \to \mathbb{C}$.

Proof. The following formula is the case $t = 1$ of (44):

$$\phi_T(n, a_0, a_s) = \phi_1(a) + \sum_{i \in I} a_i \int_0^1 \phi_{I_i}(a(s))\phi_{I_i}(a(s))ds$$

(56)

where the left-hand side is defined by (12). We see from (12) that $\phi_T(n, \ldots, \ldots)$ has an analytic extension to $\Delta_{n,\mathbb{C}}(T)$. Also, the real linear maps

$$a \mapsto \alpha : \Delta_1(T) \to \mathbb{R}^T, \quad a \mapsto (a_0, a_s) : \Delta_1(T) \to \Delta_s(T)$$

extend to complex linear maps $\Delta_{1,\mathbb{C}}(T) \to \mathbb{C}^T$ and $\Delta_{1,\mathbb{C}}(T) \to \Delta_{s,\mathbb{C}}(T)$. We can therefore use (56) recursively to construct the desired analytic extension of $\phi_1$.

Proof of Proposition 6.6. Since $Q_{1,k}(a, z)$ is continuous in $z = (z_1, \ldots, z_{n+1})$ on $\mathcal{O}_S$, analytic in $a$, and uniformly bounded on compacts in $\Delta_{1,\mathbb{C}}(T)$, the right-hand side of (53) is a well-defined multiple contour integral, does not depend on the order of integration, does not depend on the choice of admissible family $(\gamma_1, \ldots, \gamma_{n+1})$, and defines an analytic function $\psi_1$ on $\Delta_{1,\mathbb{C}}(T)$. Set

$$\delta_1(a) = \phi_1(a) - \psi_1(a).$$

Then $\delta_1$ is also analytic on $\Delta_{1,\mathbb{C}}(T)$ by Proposition 6.8. We will show by induction on $n$ that $\delta_1(a) = 0$.

For $n = 0$, this follows from Proposition 2.5. Suppose inductively that the statement holds for $n - 1$ and let $l$ be a splittable combinatorial planar loop with $n$ intersections. Fix $i \in I_l$, to be chosen later, and write $k_l$ and $k_r$ for the labels in $l_{i,l}$ and $l_{i,r}$ of the faces containing the face $k$ in $l$. For $a \in \Delta_1(T)$, write $a_l$ and $a_r$ for the images of $a$ under the natural submersions

$$\Delta_{1,\mathbb{C}}(T) \to \Delta_{l_{i,l},\mathbb{C}}(T), \quad \Delta_{1,\mathbb{C}}(T) \to \Delta_{l_{i,r},\mathbb{C}}(T).$$

For $(z_1, \ldots, z_{n+1}) \in \mathbb{C}^{n+1}$, set

$$z_l = (z_j : s_j \in S_{l_{i,l}}), \quad z_r = (z_j : s_j \in S_{l_{i,r}}).$$

Then, for $a \in \Delta_{l,\mathbb{C}}(T)$ and $s \in S$, we have

$$\mathcal{E}_i(n_s, a) = \begin{cases} 1, & \text{if } s \text{ uses the right outgoing edge at } i, \\ -1, & \text{if } s \text{ uses the left outgoing edge at } i, \\ 0, & \text{otherwise.} \end{cases}$$

Hence

$$\mathcal{E}_i Q_{1,k}(a, z) = Q_{l_{i,l},k_l}(a_l, z_l)Q_{l_{i,r},k_r}(a_r, z_r).$$

(57)

Since $n \geq 1$, the tree $S_l$ has at least two leaves, and one of them, say $s_m$, is not the boundary of the distinguished face $k$. Since the labelling is adapted, there exists $p \leq m - 1$ such that $s_p$ is adjacent to $s_m$. Denote by $k_c$ the component of its complement which does not include $k_\infty$ and set $i \in I_l$ to be the intersection point $s_m$ and $s_p$ are sharing. The sequence $(s_1, \ldots, s_{m-1}, s_{m+1}, \ldots, s_n)$ is an adapted labelling of $l_{i,l}$ and the family of loops $(\gamma_1, \ldots, \gamma_{m-1}, \gamma_{m+1}, \ldots, \gamma_n)$ is admissible for this sequence and for the distinguished face $k_l$. Also, $s_m$ is an adapted labelling of $l_{i,r}$ with admissible loop...
$\gamma_m$. Since the right-hand side of (57) is uniformly bounded on any compact subset of $\Delta_{l,C}(T) \times O_n$, we deduce that, for all $a \in \Delta_{l,C}(T)$,

$$\mathcal{E}_l \psi_l(a) = \psi_{l,l}(a_l) \psi_{l,r}(a_r).$$

On the other hand, since $\Phi_T$ satisfies the Makeenko–Migdal equations, for all $a \in \Delta_l(T)$,

$$\mathcal{E}_l \phi_l(a) = \phi_{l,l}(a_l) \phi_{l,r}(a_r)$$

and this extends to $a \in \Delta_{l,C}(T)$ by analyticity. But $l_{i,l}$ and $l_{i,r}$ are splittable and have no more than $n - 1$ points of intersection. So we have shown that, for all $a \in \Delta_{l,C}(T)$,

$$\mathcal{E}_l \delta_l(a) = 0. \quad (58)$$

We check now the boundary condition of this equation. Since $l$ is splittable, there is a splittable loop $\tilde{l}$, with exactly $n - 1$ intersections, an affine map

$$\iota_c : \Delta_l(T) \cap \{a : a_k = 0\} \to \Delta_{\tilde{l}}(T)$$

and a distinguished face $\tilde{k} \in F_{\tilde{l}}$ such that, for any $a \in \Delta_l(T)$ with $a_k = 0$,

$$l(a) \cap \tilde{l}(\iota_c(a)) \neq \emptyset$$

and $\iota_c(a)_{\tilde{k}} = 0$ if and only if $a_k = 0$. Moreover, for all $a \in \Delta_l(T)$,

$$\phi_l(a) = \phi_{\tilde{l}}(\iota_c(a)). \quad (59)$$

Furthermore, by analyticity of $\phi_l$ and $\phi_{\tilde{l}}$, this equality holds true for all $a \in \Delta_{l,C}(T)$ with $a_k = 0$. Let $v \in \mathbb{Z}^{F_l}$ be the vector with $v_k = 1$ which is proportional to $\mathcal{E}_l$, viewed as an element of $\{1_{F_l}\}^T \cap \mathbb{R}^{F_l}$, where $i$ is the only vertex adjacent to $F_c$. Then, by (58), for all $a \in \Delta_{l,C}(T)$,

$$\psi_l(a) = \psi_l(a - a_k v).$$

As $a - a_k v \in \Delta_{l,C}(T) \cap \{a : a_k = 0\}$, by (59), in order to conclude, it is sufficient to show that, for all $a \in \Delta_{l,C}(T)$ with $a_k = 0$,

$$\phi_l(a) = \phi_{\tilde{l}}(\iota_c(a)).$$

For such a vector $a$ and for $z \in O_n$, set $\tilde{z} = (z_j : j \neq m)$. Then

$$Q_{l,k}(a, z) = Q_{l,k}(a, \tilde{z}) \frac{e_m e_{m}G_{T}(z_m)}{z_m - z_p}.$$

For $a \in \Delta_{l,C}(T)$, the only singularity of $z_m \in \mathbb{C}\setminus[-\beta, \beta] \mapsto Q_{l,k}(a, z)$ is at $z_p$. Since the family of loops $(\gamma_1, \ldots, \gamma_{n+1})$ is admissible, by deforming $\gamma_m$, we can assume that the bounded component of $\mathbb{C}\setminus\gamma_m$ contains all $\gamma_j$ with $j \neq \theta$. Then, for all $\tilde{z} \in O_{n-1}$,

$$\frac{1}{2\pi i} \int_{\gamma_m} Q_{l,k}(a, z) dz_o = Q_{l,k}(a, \tilde{z}) \frac{1}{2\pi i} \int_{\mathbb{C}} e_{m}G_{T}(z_m) \frac{1}{z_m - z_p} dz_m.$$
with $C$ an anticlockwise circle with centre 0, whose interior contains all contours ($y_j : j \neq m$). Since $G_T(z) \sim 1/z$ as $z \to \infty$, it follows that
\[
\frac{1}{2\pi i} \int_C e^{\varepsilon_m G_T(z_m)} z_m - z_p \, dz_m = -\frac{1}{2\pi i} \int_{1/C} e^{\varepsilon_m G_T(1/y)} y(1 - y z_p) \, dy = 1.
\]
Therefore, performing the integration in $\phi_l(a)$ first with respect to $z_m$, we obtain, when $a \in \Delta_{l,C}(T)$, with $a_{kc} = 0$,
\[
\phi_l(a) = \left( \frac{1}{2\pi i} \right)^n \int_{j \notin \gamma_l, \text{ for } j \neq m} Q_{l,k}(a, (z_\beta)_{\beta \in \Sigma_l \setminus \{s_m\}}) \prod_{j \neq m} dz_j = \phi_l(l_c(a)).
\]
