Lattices with exponentially large kissing numbers

Serge Vlăduț

Abstract. We construct a sequence of lattices \( \{L_n \subset \mathbb{R}^n\} \) for \( n \to \infty \), with exponentially large kissing numbers, namely, \( \log_2 \tau(L_n) > 0.0338 \cdot n - o(n) \). We also show that the maximum lattice kissing number \( \tau^l_n \) in \( n \) dimensions verifies \( \log_2 \tau^l_n > 0.0219 \cdot n - o(n) \).

AMS 2010 Classification: 11H31, 11H71, 14G15, 52C17;

1 Introduction

In this paper we consider lattice packings of spheres in real \( n \)-dimensional space \( \mathbb{R}^n \) and their kissing numbers. Recall that the maximum kissing number is known only in a handful of dimensions, the largest being \( n = 24 \) for which the Leech lattice \( \Lambda_{24} \) gives the optimal kissing number \( \tau(\Lambda_{24}) = 196560 \). Recall also, that the random choice procedure guarantees ([Ch],[Sh],[W]) the existence of non-lattice packings \( P_n \) with \( \log_2 \tau(P_n) \geq \log_2 \frac{2}{\sqrt{3}} \approx 0.2075 \ldots \), the upper bound of Kabatianski-Levenstein [KL] being 0.4041 \ldots. However, for lattice packings this procedure does not work, and as far as I know, no reasonable lower bound for the maximum lattice kissing number \( \tau^l_n \) is known for \( n \to \infty \). For instance, the Barnes-Wall lattices \( BW_n \) with \( n = 2^m \) give the quasipolynomial bound \( \tau^l_n \geq n^{c \log n} \), i.e. \( \log \tau^l_n \geq c \log^2 n \), which can hardly be qualified as "reasonable".

The main purpose of the present paper is to give an exponential lower bound for \( \tau^l_n \). This is achieved by applying Constuctions D and E from [BS],[BCS] to codes from [ABV] having exponentially many light vectors. In order to apply Constructions D and E we need specific good curves (the curves in the Garcia-Stichtenoth towers [GS],[GS1] do not perfectly match our construction) and some Drinfeld modular curves [Ge1],[E] perfectly suit our purposes.

Our main result is

Theorem 1.1 We have

\[
\frac{\log(\tau^l_N)}{N} \geq \frac{1}{20} \left( 1 - \frac{2 \log 33}{31} \right) - \frac{2 + 2 \log N}{N}
\]  

(1.1)
for $N = 5 \cdot 2^{10n+2}$ and any $n \geq 2$; also,
\[
\frac{\log(\tau_N)}{N} \geq \frac{1}{24} \left( 1 - \frac{2 \log 65}{63} \right) - \frac{2 + 2 \log N}{N} \tag{1.2}
\]
for $N = 3 \cdot 2^{12n+3}$ and any $n \geq 2$;
\[
\frac{\log(\tau_N)}{N} \geq \frac{1}{28} \left( 1 - \frac{2 \log 129}{127} \right) - \frac{2 + 2 \log N}{N} \tag{1.3}
\]
for $N = 7 \cdot 2^{14n+2}$ and any $n \geq 2$, where
\[
\frac{1}{20} \left( 1 - \frac{2 \log 33}{31} \right) \simeq 0.033727..., \quad \frac{1}{24} \left( 1 - \frac{2 \log 65}{63} \right) \simeq 0.033700..., \quad \frac{1}{28} \left( 1 - \frac{2 \log 129}{127} \right) \simeq 0.0317709...
\]
All our logarithms are binary.

**Corollary 1.2** We have
\[
\frac{\log(\tau_N)}{n} \geq c_0
\tag{1.4}
\]
for some $c_0 > 0$ and any $n \geq 1$.

The exact value of $c_0$ is not clear, but $c_0 = 0.02$ is probably sufficient.

It is possible to ameliorate the constants slightly, if we do not insist on the effectivity of results:

**Theorem 1.3** We have
\[
\frac{\log(\tau_N)}{N} \geq \frac{1}{20} \left( \frac{21}{31} - \log \frac{1024}{1023} \right) - o(1) \simeq 0.033800... - o(1) \tag{1.5}
\]
for $N = 5 \cdot 2^{10n+2}$,
\[
\frac{\log(\tau_N)}{N} \geq \frac{1}{24} \left( \frac{17}{21} - \log \frac{4096}{4095} \right) - o(1) \simeq 0.033715... - o(1) \tag{1.6}
\]
for $N = 3 \cdot 2^{12n+3}$,
\[
\frac{\log(\tau_N)}{N} \geq \frac{1}{28} \left( \frac{113}{127} - \log \frac{16384}{16383} \right) - o(1) \simeq 0.031774... - o(1) \tag{1.7}
\]
for $N = 7 \cdot 2^{14n+2}$.

In fact, the implied functions in $o(1)$ terms can be made explicit, but they decrease slowly and their precise calculation is not justified.
Corollary 1.4  We have
\[
\limsup_{n \to \infty} \frac{\log(\tau_n^l)}{n} \geq \frac{1}{20} \left( \frac{21}{31} - \log \frac{1024}{1023} \right).
\]

For the lower limit we can prove

Theorem 1.5  Denote \( A = \log \frac{4096}{4095} \). We have then
\[
\liminf_{n \to \infty} \frac{\log(\tau_n^l)}{n} \geq \frac{(17 - 21A)\delta_0}{504} \simeq 0.021937\ldots, \tag{1.8}
\]
where \( \delta_0 \simeq 0.6506627\ldots \) is the unique root of the equation
\[21H(\delta) = 2\delta(4 + 21A + (17 - 21A)\delta)\]
in the interval \((0.5, 1)\).

One can think that \( c_0 \) in (1.4) can be chosen rather close to that value.

The rest of the paper is organized as follows: in Section 2 we recall some basic definitions and results on lattices and error-correcting codes. Section 3 is devoted to Constructions D and E from [BS], [BCS], while Section 4 recalls and slightly modifies the constructions from [ABV]. We describe some known good curve families in Section 5 and prove our results in Section 6.

Acknowledgement. I thank G. Kabatianski for drawing my attention to the problem of asymptotics for lattice kissing numbers.

2 Preliminaries

In this section we recall some basic definitions and results on lattices and linear error-correcting codes.

2.1 Lattice packings

A sphere packing is a configuration of nonintersecting equal open spheres in \( \mathbb{R}^N \). Let \( d \) be the diameter of the spheres; then the distance between any two sphere centers is at least \( d \). Thus a packing is a set of points \( P \) in \( \mathbb{R}^N \) such that the minimum distance between any two of them is at least \( d \). If \( P \) is an additive subgroup of \( \mathbb{R}^N \) it is called a lattice or a lattice packing; below we are concerned mainly with such packings. For any packing \( P \) its density \( \Delta(P) \) is defined as the fraction of space covered by spheres (which can be defined as the upper limit of this fraction inside a large cube of tending to infinity size).

If \( L \) is a lattice then a choice of basis gives an embedding \( \epsilon_L : \mathbb{Z}^n \to \mathbb{R}^n \); its matrix is called a generating matrix of the lattice. For the diameter of spheres one can take \( d(L) = \min\{|v| : v \in L, v \neq 0\} \). For any packing \( P \subset \mathbb{R}^n \) the ratio \( \nu(P) = \Delta(P)/V_n \) is called its center density, where \( V_n = \frac{n^n}{\Gamma(n/2+1)} \) is the volume of the unit sphere.
The ratio $\lambda(P) = \log \Delta(P)/n$ is called the density exponent of $P$; thus, $\Delta(P) = 2^{-\lambda(P)n}$. The Minkowski bound, which is a corollary of the Minkowski-Hlavka theorem, says that some lattice families $\{L_n \subset \mathbb{R}^n\}$ satisfy $\lambda(L_n) \leq 1$; however, no construction is known for such families. On the other hand, the Kabatiansky-Levenstein bound says that $\lambda(P_n) \geq 0.599 - o(1)$ for any family of packings $\{P_n \subset \mathbb{R}^n\}$. Families of packings with $\liminf_{n \to \infty} \lambda(P_n) < \infty$ are called asymptotically good. It is not easy to construct such families, especially for lattice packings. The best known results in that direction use algebraic geometry codes and similar constructions (see [LT],[RT]).

Another important parameter of a packing $P \subset \mathbb{R}^n$ is its kissing number

$$\tau(P) = \max_{x \in P} \{|\{y \in P : |x - y| = d\}|$$

A random choice argument gives (see [Ch],[Sh]) the existence of (non-lattice) packings $P_n \subset \mathbb{R}^n$ with

$$\liminf_{n \to \infty} \frac{\log \tau(P_n)}{n} \geq \log \frac{2}{\sqrt{3}} \approx 0.2075\ldots,$$

whereas the Kabatiansky-Levenstein bound [KL] for $\tau$ says that

$$\limsup_{n \to \infty} \frac{\log \tau(P_n)}{n} \leq 0.4041\ldots.$$

We will say that a family of packings $P_n \subset \mathbb{R}^n$ is $\tau$-asymptotically good whenever

$$\limsup_{n \to \infty} \frac{\log \tau(P_n)}{n} > 0.$$

Since the random choice argument does not work for lattices, it is not clear whether $\tau$-asymptotically good lattice families exist, and our main purpose is to confirm their existence.

### 2.2 Error-correcting codes

Let us recall several facts about (linear error-correcting) codes; for additional information we refer to [MWS]; see also [TVN, Ch. 1]. We fix a finite field $\mathbb{F}_q$. A $q$-ary linear code is simply a subspace $C \subseteq \mathbb{F}_q^n$, where $n$ is called the length of $C$, and the ratio $R = k/n$ for $k = \dim C$ is called the rate of $C$. The minimum distance $d = d(C)$ is the minimum Hamming weight $wt(c)$, i.e. the number of nonzero coordinates, of $c \in C \setminus \{0\}$; the ratio $\delta = d/n$ is called the relative minimum distance. We say in this case that $C$ is an $[n,k,d]_q$-code. A choice of basis in $C$ defines a linear map $\varphi_C : \mathbb{F}_q^k \to \mathbb{F}_q^n$ and its matrix is called a generating matrix of $C$. A set of codes $C_1 \subset \ldots \subset C_m \subseteq \mathbb{F}_q^n$ is called a nested family. For $C \subseteq \mathbb{F}_q^n$ its dual code $C^\perp$ is the orthogonal complement of $C$:

$$C^\perp = \{v \in \mathbb{F}_q^n : v \cdot c = 0, \ \forall c \in C\},$$
where \( v \cdot c = v_1 c_1 + \ldots + v_n c_n \); \( C^\perp \) is an \([n, n-k, d^\perp]_q\)-code for some \( d^\perp \).

A random choice argument shows that asymptotically for \( n \to \infty \) and fixed \( \delta \) the rate \( R \) of the best linear codes satisfies the Gilbert-Varshamov bound

\[
R = R_q(\delta) \geq 1 - H_q(\delta) = 1 - \frac{\delta \log(q-1) + H(\delta)}{\log q}
\]

where \( H(\delta) = -\delta \log \delta - (1-\delta) \log(1-\delta) \) is the binary entropy function.

### 2.3 Algebraic geometry codes

All our curves here and below are smooth projective absolutely irreducible over a finite field \( \mathbb{F}_q \); let \( X \) be such a curve of genus \( g \), let \( D \) be an \( \mathbb{F}_q \)-rational divisor of degree \( a \geq g-1 \), and let (see, e.g., [TVN], Sec.2.2)

\[
L(D) = \{ f \in \mathbb{F}_q(X) : (f) + D \geq 0 \}
\]

be the associated function space. For a set \( \mathcal{P} = \{ P_1, \ldots, P_n \} \) of \( \mathbb{F}_q \)-rational points on \( X \) with \( \mathcal{P} \cap \text{Supp} \, D = \emptyset \) the evaluation map

\[
ev_{\mathcal{P}} : L(D) \to \mathbb{F}_q^n, \quad ev_{\mathcal{P}}(f) = (f(P_1), \ldots, f(P_n))
\]

is well defined. Whenever \( a < n \) this map is injective and its image is a linear \( q \)-ary code \( C(X, D, \mathcal{P}) \) of length \( n \), dimension \( k \geq a - g + 1 \) (by the Riemann-Roch theorem), and distance \( d > n-a \) (since the number of zeros of a function cannot exceed the number of poles). If \( D = aP_0 \) for an \( \mathbb{F}_q \)-rational point \( P_0 \neq P_i \), \( i = 1, \ldots, n \), we get a nested family of codes \( C_a \) for \( a = n-1, n-2, \ldots, g-1 \). In the particular case \( g = 0, a \geq 0 \), \( P_0 = \infty \) (i.e., \( X \) is the projective line) we get nested Reed-Solomon codes with parameters \( n = q, k = a+1, d = q-a \).

Algebraic geometry codes (AG-codes below) have good parameters when the ratio of the number of \( \mathbb{F}_q \)-rational points on the curve to its genus is high enough. The Drinfeld-Vlăduţ bound says that asymptotically this ratio cannot exceed \( \sqrt{q} - 1 \). For \( q = p^{2h} \) there exist many families of curves over \( \mathbb{F}_q \) attaining this bound (see, e.g., Section 5 below) which implies the lower bound

\[
R_q(\delta) \geq 1 - \frac{1}{\sqrt{q} - 1}
\]

for the best asymptotical rate of \( \mathbb{F}_q \)-linear codes (see, e.g., [TVN] Section 4.5). If \( q \geq 49 \) it improves (on some interval) the Gilbert-Varshamov bound.

One can dispense with the above condition \( \mathcal{P} \cap \text{Supp} \, D = \emptyset \) not spoiling the parameters of the codes \( C(X, D, \mathcal{P}) \); for instance, if \( P_i \in \text{Supp} \, D \) we can replace the term \( f(P_i) \) in \( ev_{\mathcal{P}} \) by \( f_i(P_i) \) with \( f_i = t_i^s f \), where \( t_i \) is some fixed local parameter at \( P_i \) and \( s \) is a suitable integer (see [TVN], Section 4.1, pp. 194-197, where the \( H \)- and \( P \)-constructions are discussed).
3 Constructions D and E

We recall now two constructions from [BS], [BCS] (see also Chapter 8 in [CS]), which permit to construct good lattices from good codes.

3.1 Construction D

Let \( C_0 = \mathbb{F}_2^n \supset C_1 \supset \ldots \supset C_a, \ a \geq 1 \) be a finite decreasing family of linear binary codes with parameters \([n, k_i, d_i] \) for \( C_i, i = 0, \ldots, a \), where \( d_i = 4^i \) (we will need only the case \( n = 2^{2a+1} \) and thus \( \delta_a = d_a/n = 1/2 \)). We can and will consider \( C_0 \) as a subset of \( \mathbb{R}^n \). We choose a basis \( c_1, \ldots, c_n \) for \( \mathbb{F}_2^n \) such that \( c_1, \ldots, c_{k_i} \) span \( C_i \) for \( i = 0, \ldots, a \) and define \( L \) as the lattice in \( \mathbb{R}^n \) generated by \((2\mathbb{Z})^n\) and the vectors \( \{c_j \cdot 2^i\} \) for \( i = 1, \ldots, a, k_i+1 \leq j \leq k_i \). Then we have ([BS], Theorem 1):

**Proposition 3.1** The lattice \( L \) has minimum distance \( d_L = 2 \) and its center density satisfies

\[
\delta \geq 2^{K-n}\]

for \( K = \sum_{i=1}^a k_i \).

Note that we will need only the statement \( d_L = 2 \) which is easy in view of the minimum distances \( d_i \) of \( C_i \) for \( i = 0, \ldots, a \).

3.2 Construction E

Here we need more elaborated techniques.

First we define \( T \)-lattices as follows ([BCS], [BS], cf. [LT]): a lattice \( \Lambda \subset \mathbb{R}^m \) is a \( T \)-lattice if it satisfies the following four conditions.

(i) The minimal vectors of \( \Lambda \) span \( \Lambda \).

(ii) There is a linear map \( T \) from \( \mathbb{R}^m \) to \( \mathbb{R}^m \) that sends all the minimal vectors of \( \Lambda \) into elements of \( \Lambda \) which have norm \( R^2 \) and are at a distance \( R \) from \( \Lambda \) for some \( R > 0 \).

(iii) There is a positive integer \( \nu \) dividing \( m \) and an element \( A \in \text{Aut}(\Lambda) \) such that

\[
(iii)_1 T^\nu = \frac{1}{2} A \quad \text{and} \quad (iii)_2 \frac{1}{2}(A^2 - A) = \sum_{i=0}^{\nu-1} a_i T_i, \ a_i \in \mathbb{Z}.
\]

We set \( b = m/\nu \) and \( q = 2^b \).

(iv) \( \Lambda \subseteq T \Lambda \) and

\[
(iv)_1 |TA : \Lambda| = q.
\]

It follows from \( (iii)_1 \) that \( T = tP \) where \( t = 2^{1/2} \) and \( P \) is an orthogonal transformation satisfying \( P^\nu = A \). If \( M \) is the minimal square norm of \( \Lambda \), we have \( t = R/\sqrt{M} \), and from \( (iv)_1 \) we get

\[
(v) t^m = |\det T| = 2^{-b} = q^{-1}.
\]
Note that the square lattice $\mathbb{Z}^2$ is a $T$-lattice with $T = \frac{1}{\sqrt{2}} R_{\pi/4}$ for the rotation $R_{\pi/4}$ through the angle $\pi/4 = 45^\circ$.

Construction E produces from a $T$-lattice together with a nested family of linear codes $C_0 = \mathbb{F}_{2^b}^n \supset C_1 \supset \ldots \supset C_a$ over $\mathbb{F}_{2^b}$ another $T$-lattice $L \subset \mathbb{R}^{mn}$ in the following way.

We suppose that the parameters of the code $C_i$, $0 \leq i \leq a$ are $[n, k_i, d_i]$ and we choose a basis $c_1, \ldots, c_n$ for $\mathbb{F}_{2^b}^n$ such that $c_1, \ldots, c_{k_i}$ span $C_i$ for $i = 0, \ldots, a$. Define then the lattices $\Lambda_i$ as follows. Let $v_1, \ldots, v_m$ be minimal vectors of $\Lambda$ that span $\Lambda$. Then $Tv_1, \ldots, Tv_m$ span $T\Lambda$ and $T\Lambda/\Lambda$ is an elementary abelian group of order $q$, so that there are $b$ vectors $u_1^{(1)} = T v_{r_1}, \ldots, u_b^{(1)} = T v_{r_b}$, for appropriate $r_1, \ldots, r_b$, such that $T\Lambda/\Lambda$ is isomorphic to the $\mathbb{F}_2$-lattice together with a nested family of $\mathbb{F}_2$-lattices. Let

$$\Lambda_i = T^i \Lambda, \quad u_j^{(i)} = T^i v_{r_j}, \quad j = 1, \ldots, b \text{ for all } i \in \mathbb{Z}.$$ 

The lattice $\Lambda_i$ has minimal square norm $t^{2i} M$, and $\text{dist}(u_1^{(1)}, \Lambda_i) \geq t^{i-1} R$.

Define now the maps $\sigma_i : \mathbb{F}_q^n \rightarrow \Lambda_i$ by

$$\sigma_i \left( \sum_{j=1}^b \alpha_j \omega_j \right) = \sum_{j=1}^b \alpha_j u_j^{(i)}$$

for some generators $\omega_1, \ldots, \omega_b$ for $\mathbb{F}_q$ over $\mathbb{F}_2$ and any $\alpha_j \in \mathbb{F}_2$, $j = 1, \ldots, b$; those maps define the maps $\sigma_i : \mathbb{F}_q^n \rightarrow \mathbb{R}^{mn}$.

The construction. The lattice $L \subset \mathbb{R}^{mn}$ consists of all vectors of the form

$$x = l + \sum_{i=1}^a \sum_{j=1}^{b k_i} \alpha_j^{(i)} \sigma_i (c_j)$$

for $l \in \Lambda^n, \alpha_j^{(i)} \in \mathbb{F}_2$. Note that $L$ is a $T$-lattice, since it inherits $T$ from $\Lambda$; the parameter $t$ remains the same, while $b$ becomes $b h$, see also Proposition 4.2 below. The main property of this Construction E, which coincides with Construction D for $\Lambda = 2\mathbb{Z}$ is ([BS, Theorem 3]):

**Proposition 3.2** The lattice $L$ is fixed under the transformation $\tilde{A}$ which applies $A$ simultaneously to each component and its minimum distance equals

$$\sqrt{M} \quad \text{for} \quad M = \min_{i=1, \ldots, a} \{ M, d_i R^{2i} M^{1-i} \}.$$ 

Theorem 3 of [BS] gives also the density of $L$, but we do not need it.

Applying Construction E to $\mathbb{Z}^2$ with $a = 1, M = 4, R = \sqrt{2}$ and the single parity check $[2, 1, 2]_q$ code $C_1$, we get successfully the $T$-lattices $D_4, E_8, \Lambda_{16}, \tilde{\Lambda}_{32}$ in the corresponding dimensions; one can take this description as a definition for those lattices. Moreover, applying Construction E to $D_4$ and the single parity check $[m, m-1, 2]_4$ code for any $m \geq 2$ we get a $T$-lattice $\Lambda_{4m}$ in $4m$ dimensions. The Leech lattice $\Lambda_{24}$ is also a $T$-lattice (see [BCS], p.177); note, however that $\Lambda_{24} \neq \tilde{\Lambda}_{24}$.
4 Codes with many light vectors

Recall the following principal result of [ABV]:

**Theorem 4.1** Let \( q = 2^{2s}, s = 3, 4, \ldots \) be fixed. Then for any \( \delta_1 < \delta < \delta_2 \) there exists a sequence of binary linear codes \( \{ C_n \} \) of length \( n = qN, N \to \infty \) and distance \( d_n = n\delta/2 \) such that

\[
\frac{\log A_{d_n}}{n} \geq \frac{E_s(\delta)}{2^{2s}} - o(1) \tag{4.1}
\]

Here \( A_{d_n} \) is the number of minimum weight vectors in \( C_n \), and the function

\[
E_s(\delta) = H(\delta) - \frac{2s}{2^s - 1} - \log \frac{2^{2s}}{2^s - 1} \tag{4.2}
\]

has two zeros \( 0 < \delta_1 < \delta_2 < 1 - 2^{-2s} \) and is positive for \( \delta_1 < \delta < \delta_2 \). In particular, for \( s = 3, q = 64, \delta = 1/2 \) we have

\[
E_3(0.5) = \frac{1}{7} \log \frac{64}{63} \simeq 0.1201..., \quad \frac{E_3(0.5)}{64} \simeq 0.001877... .
\]

Theorem 4.1 is a simple consequence of the following result concerning AG codes. Consider a curve \( X \) of genus \( g \) over \( \mathbb{F}_q \), where \( q = 2^{2s}, s \geq 3 \). Suppose that \( N \geq (2^s - 1)g \) where \( N = |X(\mathbb{F}_q)| \) is the number of \( \mathbb{F}_q \)-rational points of \( X \) (e.g., \( X \) is a curve from Subsections 5.1, 5.2 below). Let \( D \) be an \( \mathbb{F}_q \)-rational positive divisor of degree \( a > 0 \), and let \( C = C(X, D, X(\mathbb{F}_q)) \) be the corresponding AG code of length \( N \), dimension \( k(C) \geq a - g + 1 \), and distance \( d(C) \geq N - a \).

**Proposition 4.2** Let \( \delta = (N - a)/N \) satisfy the inequality \( \delta_1 < \delta < \delta_2 \). Then there exists an \( \mathbb{F}_q \)-rational positive divisor with \( \deg(D) = a \) such that the corresponding AG code \( C \) has the minimum distance \( d = N - a = \delta N \) and for the number \( A_d \) of vectors of weight \( d \) we have

\[
\log A_d \geq NE_s(d) - o(N).
\]

Recall that this is proved using an averaging procedure applied to the set of linearly equivalent classes of \( \mathbb{F}_q \)-rational positive divisors \( D \) with \( \deg(D) = a \) which form the set \( J_X(\mathbb{F}_q) \) of \( \mathbb{F}_q \)-rational points on the Jacobian \( J_X \) of \( X \). This result is based on the estimate

\[
\frac{\log |J_X(\mathbb{F}_q)|}{g} = q + (\sqrt{q} - 1) \log \frac{q}{q - 1} + o(1) .
\]

In order to deduce Theorem 4.1 from Proposition 4.2 we take the binary simplex code, that is, the linear code dual to \( [n = q - 1, n - 2s, 3] \) Hamming code and augment each vector in it with a zero coordinate. This gives a binary linear \( [q, 2s, q/2] \) code \( C_0 \) in which every nonzero vector has Hamming weight
Using then a linear bijection $\varphi : \mathbb{F}_q \rightarrow C_0$ and replacing every coordinate by its image, we obtain from $C(D)$ a linear binary code $C_n$ in Theorem 4.1.

**Remark 4.1.** Proposition 4.2 is valid for any even prime power $q \geq 49$, but we do not use this below. Note also that its proof guarantees in general only the existence of one divisor class $D$ satisfying the conclusion (and not of exponentially many such divisor classes); however, when the bound is strictly bigger than $k(C)$, we get exponentially many such divisor classes in $J_X(\mathbb{F}_q)$.

**Effective version.** Note that at the expense of a small decline in parameters the above estimate can be made completely explicit, namely, we have

**Theorem 4.3** Let $q = p^h$ be a prime power, let $X$ be a curve of genus $g$ over $\mathbb{F}_q$, let $S \subseteq X(\mathbb{F}_q), |S| = N$, and let $a \in \mathbb{N}$ with $1 \leq a \leq N - 1$. Then there exists an $\mathbb{F}_q$-rational positive divisor $D \geq 0, \deg(D) = a$ such that the corresponding AG code $C = C(X, D, S)$ has the minimum distance $d = N - a = \delta N$ and we have

$$A_d \geq \frac{\binom{N}{a}}{\left(\sqrt{q} + 1\right)^{2g}}.$$

The proof simply replaces the asymptotic inequality (4.3) by a simpler effective inequality

$$|J_X(\mathbb{F}_q)| \leq \left(\sqrt{q} + 1\right)^{2g}.$$

Applying Stirling’s formula, we get

**Corollary 4.4** We have

$$\log A_d \geq H(\delta) - \frac{2g}{N} \log\left(\sqrt{q} + 1\right) - \frac{\log(2\pi ad)}{2N} - \frac{1}{12ad}.$$

In particular, if $N = 2a = 2d \geq (\sqrt{q} - 1)g$, then

$$\frac{\log A_d}{N} > 1 - \frac{2\log(\sqrt{q} + 1)}{\sqrt{q} - 1} - \frac{2 + 2\log N}{N}.$$

Note, that Theorem 4.3 and Corollary 4.4 are applicable, e.g., for $g = 0$, where we get an estimate for the Reed-Solomon codes.

### 5 Some good families of curves

We recall now some constructions of curves over $\mathbb{F}_q$ with many rational points. Let $q$ be a prime power (we will be interested only by the case $q = p^{2h}$), and let

$$N_q(g) := \max\{|C(\mathbb{F}_q)| : C \text{ is a curve of genus } g \text{ over } \mathbb{F}_q\}.$$

Define then

$$A(q) := \lim_{g \to \infty} \sup \frac{N_q(g)}{g} \leq \sqrt{q} - 1, \quad A^-(q) := \lim_{g \to \infty} \inf \frac{N_q(g)}{g}$$

as the corresponding upper and lower asymptotic quantities. We begin with some families attaining the bound for $A(q)$ (the Drinfeld-Vlăduţ bound).
5.1 Garcia-Stichtenoth tower

The tower $X_n, n = 1, 2, \ldots$ from [GS1] is defined recursively by the equations

$$x^q_i + x_{i+1} = \frac{x^q_i}{x^q_{i-1} + 1}, \text{ for } i = 1, \ldots, n-1. \quad (5.1)$$

Therefore, the function field $T_n := \mathbb{F}_{q^2}(X_n)$ of the curve $X_n$ is given by $T_n = \mathbb{F}_{q^2}(x_1, \ldots, x_n)$ where $x_i, i = 1, \ldots, n$ are related by (5.1). The main result of [GS1] gives the parameters of that tower.

**Theorem 5.1** We have

(i) for the genus $g_n = g(X_n)$:

$$g_n = (q^m - 1)^2 \text{ for } n = 2m,$$

$$g_n = (q^m - 1)(q^{m-1} - 1) \text{ for } k = 2m - 1,$$

and the number $N(n) = |X_n(\mathbb{F}_{q^2})|$ of $\mathbb{F}_{q^2}$-rational points of $X_n$ satisfies

$$N(n) \geq (q - 1)q^n.$$

Let then describe an optimal tower of Drinfeld curves closely related to the tower $X_n$.

5.2 Drinfeld modular curves

The general reference for Drinfeld modular curves is [Ge], but we use a particular case from [E] (cf. [Ge1]).

**A tower of Drinfeld curves.** For any field $L \supseteq \mathbb{F}_q$, we denote by $L\{\tau\}$ the non-commutative $L$-algebra generated by $\tau$ and satisfying the relation $\tau a = a^q \tau$ for all $a \in L$. Let $A = \mathbb{F}_q[T]$; then a rank 2 Drinfeld module $\varphi$ over $A$ is an $\mathbb{F}_q$-algebra homomorphism from $A$ to $L\{\tau\}$ such that

$$\varphi(T) = l_0 + l_1 \tau + l_2 \tau^2 = l_0 + g \tau + \Delta \tau^2 \in L\{\tau\} \quad (5.2)$$

with nonzero discriminant $\Delta = \Delta(\varphi)$. The map $\gamma : A \rightarrow L$ taking any $a \in A$ to the constant term of $u$ is a ring homomorphism; thus, $\gamma(T) = l_0$ in (5.2).

If $\varphi, \psi$ are two Drinfeld modules, an isogeny from $\varphi$ to $\psi$ is an element $u \in L\{\tau\}$ such that

$$u \circ \varphi_a = \psi_a \circ u$$

for all $a \in A$ and its kernel is the following $A$-submodule of $L$:

$$\ker(u) := \{x \in L : u(x) = 0\},$$

which is of finite dimension over $\mathbb{F}_q$ unless $u = 0$. In particular, if $u = \varphi_a$ then $u$ is an isogeny from $\varphi$ to itself, called multiplication by $a$, and its kernel is isomorphic with $(A/aA)^2$ as an $A$-module for $\gamma(a) \neq 0$; elements of $\ker(a)$ are called $a$-torsion points of $\varphi$. If $\gamma$ is not injective then $\ker \gamma = Ab$ for some
irreducible $b \in A$; $\varphi$ is then said to be supersingular if $\ker(b) = \{0\}$ and for $\deg(b) = 1$, we have $\varphi_b = g\tau + \Delta \tau^2$ and $\varphi_b$ is supersingular if and only if $g = 0$.

An isomorphism between Drinfeld modules is simply an element $u \in L^*$, and it multiplies each coefficient $l_i$ in (5.3) by $u^{1-q^i}$. Let

$$J(\varphi) = \frac{g^{q+1}}{\Delta},$$

then $\varphi$ and $\psi$ with the same $\gamma$ are isomorphic over $\bar{L}$ if and only if $J(\varphi) = J(\psi)$.

Thus, we can refer to the $J$-line as the Drinfeld modular curve $X(1)$ for a given $\gamma$. Moreover, for $N \in A$ with $\gamma(N) \neq 0$, we have Drinfeld modular curves $X_0(N)$ parametrizing Drinfeld modules with a choice of torsion subgroup $G \simeq A/NA$ (and fixed $\gamma$). If $\gamma(T) \in \mathbb{F}_q$, we may regard the curves $X(1)$ and $X_0(N)$ as the reduction mod $(T - \gamma(T))$ of the corresponding modular curves for $\gamma(T) = T$. Below we suppose that $\gamma(T) = 1$ and we say that a point on $X_0(N)$ is supersingular if the corresponding Drinfeld module is supersingular; such points are $\mathbb{F}_{q^2}$-rational.

Let us consider the case $N = T^{k+1}$; for the curve $\bar{X}_k := X_0(T^{k+1})$ of genus $\bar{g}_k = g(\bar{X}_k)$ we have [Ge1, Ex.10.2]:

$$\bar{g}_k = \frac{(q^{m+1} - 1)(q^m - 1)}{q - 1} \quad \text{for} \quad k = 2m + 1,$$

and the number of supersingular points on $\bar{X}_k$ equals $q^k$.

Elkies proves in [E] that the function field $\bar{K}_k = \mathbb{F}_q(\bar{X}_k)$, $k \geq 2$ is given by

$$\bar{K}_k = \mathbb{F}_q(x_1, \ldots, x_k) \quad \text{with} \quad x_{j+1}(x_{j+1} + 1)^{q-1}(x_{j+1} + 1)^{q-1} = x_j^q, \quad j = 1, \ldots, k-1,$$

and the set of $q^k$ supersingular points of $\bar{X}_k(\mathbb{F}_{q^2})$ is determined by the conditions $\Phi_{q+1}(x_j) = 0$ for $j = 1, \ldots, k$, where $\Phi_{q+1}(t) = (t^{q+1} - 1)/(t - 1)$.

Note also that the Garcia-Stichtenoth curve $X_n$ is a degree $q + 1$ cyclic covering of $\bar{X}_n$, but we do not need this fact.

**More general Drinfeld curves.** We will need also more general Drinfeld modular curves which do not form a tower and as yet have no explicit equations. However, the family of those curves is optimal and their genera are explicitly known [Ge1]. Let $M$ be a monic element of $A$ with $M(1) \neq 0$, $\deg M \geq 3$ and let $M = \prod_{i=1}^s P_i^{r_i}$ be its prime factorization; thus each $P_i \in A$ is a monic irreducible polynomial of degree $l_i$ and $r_i \geq 1$ for $1 \leq i \leq s$. We put $q_i := q^{l_i}$ and define the arithmetic functions

$$\varepsilon = \varepsilon(M) = \prod_{i=1}^s q_i^{r_i - 1}(q_i + 1), \quad \kappa = \kappa(M) = \prod_{i=1}^s \left(q_i^{l_i - 1} + q_i^{l_i - 2}\right).$$
Consider the curve $\tilde{X}_0(M)$ over $\mathbb{F}_q$ which is the Drinfeld modular curve $X_0(M)$ with $\gamma(T) = 1$. We have then [Ge, Sections 8-10]

**Proposition 5.2** Suppose that at least one degree $l_i$ is odd. Then

(i) The curve $\tilde{X}_0(M)$ is smooth of genus $g_0(M)$ given by

$$g_0(M) = 1 + \frac{2^{s/2} - 1}{q^2 - 1} \leq \frac{\varepsilon}{q^2 - 1};$$

(ii) $|\tilde{X}_0(M)(\mathbb{F}_{q^2})| \geq \frac{\varepsilon}{q + 1} \geq (q - 1)g_0(M)$.

Therefore, for any sequence $M_i$ with $\text{deg}(M_i) \to \infty$ the family $\tilde{X}_0(M_i)$ is asymptotically optimal over $\mathbb{F}_{q^2}$.

### 5.3 Curves of every genus with many points

Note the the genera of curves in Subsections 5.1-5.2 are of a special form and thus they give no estimate for the quantity $A^-(q)$ measuring the maximal number of points on curves of every genus. However, in [EHKPWZ] it was shown that $A^-(q) \geq c\log q$ for any prime power $q$ and a positive constant $c$. Moreover, for an even square $q$ the result gets much better:

**Theorem 5.3** For $q = 2^{2h}$ we have

$$A^-(q) \geq \frac{\sqrt{q} - 1}{2 + \log q} = \frac{2^h - 1}{2 + \frac{1}{2h}}.$$

Thus $A^-(q)$ is, roughly speaking, only twice smaller than $A(q)$; a similar result holds also for the odd squares.

### 6 Proofs

We begin with an easy construction which gives a small positive constant lower bound for the ratio $\log(\tau^N)/n$ assuring thus the existence of $\tau$-asymptotically good lattice families. Indeed, let us take $N = 2^{K+1}$, $d = a = N/2 = 2^K$ for some $K \geq 2$, and let us apply Theorem 4.1 with $s = 3, q = 64$ and the Drinfeld curves $\tilde{X}_k$ over $\mathbb{F}_8$ having at least $8^k = 2^{K+1}, K = 3k - 1$, points rational over the field $\mathbb{F}_{64}$. We get then a binary $[N, k, d]$ code $C_K$ with

$$\log A_d \geq \frac{1}{64}E_3(0.5)N - o(N) = \frac{1}{64} \left( \frac{1}{4} \log \frac{64}{63} \right) N - o(N).$$

We can construct then a decreasing family $C_0 = \mathbb{F}_2^N \supset C_1 \supset \ldots \supset C_K$ defining inductively $C_{K-i}$ for $i = 1, \ldots, K - 1$ as generated by $C_{K-i+1}$ and $c_i$ for some binary vector $c_i \in \mathbb{F}_2^N$ with $wt(c_i) = 2^{K-i}$. Applying then Construction D we
get a lattice $L_N \subset \mathbb{R}^N$ with $d_L = 2$, and each minimum weight vector of $C_K$ produces a minimum norm vector in $L$. Therefore we have

$$\frac{\log \tau(L_N)}{N} \geq \frac{\log A_d}{N} \geq \frac{1}{64} \left( \frac{1}{7} - \log \frac{64}{63} \right) - o(1) > 0.00187 - o(1).$$

This formula implies Corollary 1.2 albeit with a very small $c_0$.

**Remark 6.1.** We do not care here about the density of $L$, but the constructed family is still asymptotically good albeit very poor for its density; however, it is easy to modify the construction to get a better (yet rather poor) family while conserving the ratio $\frac{\log \tau(L_N)}{N}$.

**Remark 6.2.** If we replace in the above construction the Drinfeld curve $\tilde{X}_k$ by the Garcia-Stichtenoth curve $X_k$ or $F$ applied to suitable $\tilde{T} \Lambda$ and applying Corollary 4.4 we get (1.2). If we apply the same construction to $\tilde{\Lambda}$ we get a lattice $L \subset F$ and in that sense the Garcia-Stichtenoth tower is not optimal for our construction. The same remark applies to the constructions below, but the deterioration of the parameters is always very small.

It is then clear how to proceed: we can replace Construction D by Construction E applied to suitable $T$-lattices and codes from Theorem 4.3, which we complete in an appropriate manner. The best results are obtained using the $T$-lattices $\tilde{\Lambda}_{20}$, $\tilde{\Lambda}_{24}$ (or $\tilde{\Lambda}_{24}$), and $\tilde{\Lambda}_{28}$ which the lattice families in Theorem 4.1.

More precisely, in the case of $\tilde{\Lambda}_{24}$ we take $q = 2^{12} = 4096$, the curve $\tilde{X}_k$ over $F_{64}$ having $N = 2^{12k} = 4^{6k}$ points rational over $F_{64}$, put $d = a = N/2$ and apply Construction E to $\tilde{\Lambda}_{24}$ and the family $C_0 = F_2^N \supset C_1 \supset \ldots \supset C_{6k}$ of $[N,k,4^i]$-codes over $F_{2^{12}}$ for $i = 0, \ldots, 6k$, where $d_i = 4^i$, $d_{6k} = d = N/2$ and $C_{6k-i}$ is defined inductively for $i = 1, \ldots, 6k-1$ as generated by $C_{6k-i+1}$ and $c_i$ for some vector $c_i \in F_{496}^N$ with $wt(c_i) = 4^{6k-i}$. Exactly as above, each minimum weight vector of $C_{6k}$ gives rise to a minimum norm vector of the resulting lattice $L_{24N}$ and applying Corollary 4.4 we get (1.2). If we apply the same construction to $\tilde{\Lambda}_{4m}$, $q = 2^{2m}$ and the curve $\tilde{X}_k$ over $F_q$ having $N = 2^{2mk} = 4^{mk}$ points rational over $F_q$, we get a lattice with

$$\frac{\log(\tau_N)}{N} \geq \frac{1}{4m} \left( 1 - \frac{2 \log(2^m + 1)}{2^m - 1} \right) - \frac{2 + 2 \log N}{N} \quad (6.1)$$

which gives (1.1), (1.2) and (1.3) for $m = 5, 6$ and 7, respectively (the result is $< 0.03$ for any other value of $m$).

Applying in the same way Proposition 4.1 instead of Corollary 4.4 we get the lattices with

$$\frac{\log(\tau_N)}{N} \geq \frac{1}{4m} \left( 1 - \frac{2m}{2^m - 1} - \log \frac{2^{2m}}{2^{2m} - 1} \right) - o(1) \quad (6.2)$$

and thus Theorem 4.3 for $m = 5, 6$ and 7.

We begin the proof of Theorem 1.3 with the following
Proposition 6.1. For any \( q = p^h \) there exist a monic polynomials \( M_i \in \mathbb{F}_q[T] \) for \( i = 1, 2, \ldots, \) with \( \deg M_{i+1} \geq \deg M_i \), satisfying
\[
\lim_{i \to \infty} \frac{\tilde{g}_{i+1}}{\tilde{g}_i} = 1, \quad \tilde{g}_i < \tilde{g}_{i+1}
\]
for \( \tilde{g}_i := g(\tilde{X}_0(M_i)) > 0. \)

To prove that we “densify” the tower \( \{\tilde{X}_k\} \), inserting between its consecutive levels some curves from the family \( \{\tilde{X}_0(M)\} \). Indeed, let us consider two consecutive curves \( \tilde{X}_{2m} \) of genus \( \tilde{g}_{2m} = (q^m - 1)/(q - 1) \) and \( \tilde{X}_{2m+1} \) of genus \( \tilde{g}_{2m+1} = (q^{m+1} - 1)/(q^m - 1) = qg_{2m} + O(\sqrt{g_{2m}}) \), say, for \( k = 2m \geq 100. \) Set \( s = s(k) \) for a suitable non-decreasing unbounded function \( s : \mathbb{N} \rightarrow \mathbb{N} \) (to be chosen afterwards), then the number \( P(s) \) of monic irreducible polynomials in \( A \) of degree \( s \) satisfies \( (q^s - q^{s/2})/s \leq P(s) \leq q^s/s. \) We consider then the curves \( \tilde{X}_{k,j} = \tilde{X}_0(T^{k+1-j^2}M_{s,j}) \) for \( M_{s,j} = \prod_{i=1}^j M_i(s) \), where \( \{M_1(s), \ldots, M_P(s)\} \) is the list of all monic degree \( s \) irreducible polynomials in \( A \). The genus of \( \tilde{X}_{k,j} \) equals \( \tilde{g}_{k,j} = q^{2m-s}((q^s - q^{s/2})/(q - 1) + O(\sqrt{g_{2m}}) \) which is increasing with \( j \) and \( \tilde{g}_{k,j} \) tends to 1 for growing \( k \). If \( \tilde{g}_{k,i} \) is still less than \( q^{2m+1}/q \), we can increase further the genus taking \( s+1 \) instead of \( s \) and continuing to replace the factors \( T^{s+1} \) consecutively by irreducible polynomials of degree \( s+1 \), until the expurgation of those polynomials. If \( k - sP(s) - (s+1)P(s+1) > 0 \) we can continue with the polynomials of degree \( s+2 \) and so on. The procedure stops when either we reach the genus \( g_{2m+1} \) and we have densified our level, or there is no factors \( T^i \) to replace by the next polynomial of degree, say, \( s+h, h \geq 1. \)

We want to show that choosing \( s(k) \) appropriately, we can always reach \( g_{2m+1} \) and thus densify our initial tower which will end the proof. Indeed, for a given \( s \), using all \( P(s) \) degree \( s \) irreducible polynomials, we multiply the genus by the factor \((1 + q^{-s})P(s) \simeq \exp(q^{s/2}) \). Therefore, using all irreducible polynomials of degrees from \( s \) to, say \( s+t \), we can multiply the genus by \( \exp(\frac{1}{2} + \ldots + \frac{1}{s+t}) \simeq 1 + \frac{1}{s} \), whereas this is possible whenever \( sP(s)+\ldots+(s+t)P(s+t) \simeq q^s+\ldots+q^{s+t} \leq k \). It is then sufficient to take \( t/s = q, (s+t)q^{s+t} \leq k; \) for example, we can choose \( t = (q + 1)s, s = \log k/(2q \log q) \) to guarantee those inequalities for sufficiently large \( k \), and the proof is finished (the case of an odd \( k \) is similar).

Remark 6.3. This proof can replace the sketchy proof of Claim (3.2)-(3.3) in [STV, Sec.3], equivalent to Proposition 6.1.

Let us deduce Theorem 1.1 from Proposition 6.1. Let \( q = 2^{12} = 4096, \) and let \( k \in \mathbb{N} \) satisfy \( \tilde{g}_k < n/24 \leq \tilde{g}_{k+1} \) for a given large dimension \( n; \) moreover, let \( 2^a \tilde{g}_k < n/24 \leq 2^{a+1} \tilde{g}_k \) for some \( 0 \leq a \leq 11 \) (recall that \( \tilde{g}_{k+1}/\tilde{g}_k \simeq q \)). Let us take the curve \( X_0(M_i) \) from Proposition 6.1 of genus closest to \( 2^a \tilde{g}_k \) and the curve \( X_0(M_j) \) of genus closest to \( 2^{a+1} \tilde{g}_k \). Then we construct, by Proposition 1.2, an \([N_i, k_i, 2^{a+12k} = d_i]\)-code \( C_i \) on \( X_0(M_i) \) with exponentially many light vectors and the same with \([N_j, k_j, 2^{a+112k} = d_j]\) code \( C_j \) on \( X_0(M_j) \); note that relative distances of both codes are asymptotic to \( \frac{1}{2} \) and the ratio \( N_j/N_i \) is asymptotic to \( \frac{1}{2} \).
2. We can then construct the lattices $L_{24N_i}$ and $L_{24N_j}$ in dimensions $24N_i$ and $24N_j$ using Construction E for the Leech lattice $\Lambda_{24}$ (or $\tilde{\Lambda}_{24}$) and nested families of codes beginning, respectively, by $C_i$ and $C_j$. The lattices $L_{24N_i}$ and $L_{24N_j}$ have then kissing numbers satisfying (1.6). Since $24N_i \leq n \leq 24N_j \simeq 48N_i$ the kissing number of the lattice $L_{24N_i}$ gives the following estimate

$$\frac{\log(\tau^{(1)}_n)}{n} \geq \frac{1}{24} \left( \frac{17}{21} - \log \frac{4096}{4095} \right) \delta,$$

for $\delta = \frac{24N_i}{n} \in [0.5, 1]$, whereas we can shorten the code $C_j$ deleting some $F_q$-rational points from the corresponding curve to get a code of length $\frac{n}{24}$ and then apply Construction E with $\Lambda_{24}$. This gives the estimate

$$\frac{\log(\tau^{(1)}_n)}{n} \geq \frac{1}{24} \left( \lambda H \left( \frac{1}{2\lambda} \right) - \frac{4}{21} - \log \frac{4096}{4095} \right),$$

with $\lambda \simeq \frac{1}{28} = \frac{n}{24N_j} \in [0.5, 1]$, and taking the minimax we get (1.8).

Remark 6.3. Using the lattices $\tilde{\Lambda}_{4m}$ together with the codes over $\mathbb{F}_{2^m}$ with similar properties constructed on the curves from Theorem 5.3, instead of the above "densified" curves, we get the lattices with somewhat worse parameters, which are optimal for $m = 7$ and give the estimate

$$\liminf_{n \to \infty} \frac{\log(\tau^{(1)}_n)}{n} \geq 0.020715...$$
