We derive a supersymmetric renormalization group (RG) equation for the scale-dependent superpotential of the supersymmetric $O(N)$ model in three dimensions. For a supersymmetric optimized regulator function we solve the RG equation for the superpotential exactly in the large-$N$ limit. The fixed-point solutions are classified by an exactly marginal coupling. In the weakly coupled regime there exists a unique fixed point solution, for intermediate couplings we find two separate fixed point solutions and in the strong coupling regime no globally defined fixed-point potentials exist. We determine the exact critical exponents both for the superpotential and the associated scalar potential. Finally we relate the high-temperature limit of the four-dimensional theory to the Wilson-Fisher fixed point of the purely scalar theory.

I. INTRODUCTION

Fixed points of the renormalization group (RG) play a fundamental role in statistical physics and quantum field theory $^{[1, 2]}$. Infrared (IR) fixed points dominate the long-distance behavior of correlation functions and are relevant for the understanding of continuous phase transitions and universal scaling laws $^{[3]}$. Ultraviolet (UV) fixed points control the short-distance behavior of quantum field theories. It is widely believed that the existence of an UV fixed point is mandatory for a definition of quantum field theory on a microscopic level, e.g. asymptotic freedom of QCD or asymptotic safety of gravity $^{[4, 5]}$. In general, the fixed point structure of a given theory depends on its field content, the spacetime dimensionality, the long-range or short-range nature of its interactions and the symmetries of the action.

Scalar field theories with a global $O(N)$ symmetry provide an important testing ground for fixed point studies. In three dimensions the $(\phi^2)^3$ theory displays a non-trivial IR fixed point which determines the second-order phase transition between an $O(N)$ symmetric and the symmetry broken phase as realized in many physical systems ranging from entangled polymers and water to ferromagnets or QCD with two massless flavors of quarks $^{[3, 6]}$. The $(\phi^2)^3$ theory also displays a line of first-order phase transitions whose end point, in the limit of many scalar fields, qualifies as an UV fixed point $^{[7, 8]}$.

Supersymmetry represents the global symmetry which relates bosonic to fermionic degrees of freedom. Supersymmetric theories are important candidates for extensions of the Standard Model. It is important to understand how the fixed-point structure of a non-supersymmetric theory differs from that of its supersymmetric extension, both in view of the IR and the UV behavior of the theory.

In this paper, we study fixed points of supersymmetric $O(N)$ models which consist of an $N$-component scalar field coupled to $N$ Majorana fermions. We employ non-perturbative renormalization group methods a la Wilson, based on the integrating-out of momentum modes from a path-integral representation of the theory $^{[9, 11]}$. A particular strength of this continuum method is its flexibility, allowing for the study of theories with strong correlations and large couplings. Furthermore, optimization techniques are available to control the physics content within systematic approximations $^{[12–14]}$. In the past, this method has been successfully employed for the study of critical phenomena in a variety of settings including scalar theories, fermions, gauge theories and gravity $^{[5, 15–24]}$. It has recently been extended to include supersymmetric theories $^{[25–36]}$. Our prime interest here concerns the limit of many scalar fields $1/N \to 0$, where effects induced by the fields’ anomalous dimensions are suppressed and a local potential approximation (LPA) becomes exact. Then full analytical fixed point results are obtained for the fixed points in the supersymmetric theory, allowing for a complete analytical understanding of the theory, analogous to the purely scalar theory $^{[37–39]}$.

Supersymmetric $O(N)$ models have previously been investigated with Dyson-Schwinger equations $^{[40]}$ and with the large-$N$ expansion $^{[41, 42]}$. The three-dimensional theory has also been studied at finite temperatures, where supersymmetry is softly broken $^{[43, 44]}$. The model has a peculiar phase structure concerning the breaking of the $O(N)$ symmetry: Additionally to the normal phases with a broken and an unbroken symmetry a phase with two $O(N)$ symmetric ground states and a phase with one symmetric and one non-symmetric ground state have been found. In addition, there exists a supersymmetric analogue of the Bardeen-Moshe-Bander phenomenon $^{[7]}$. The fate of this phenomenon at finite $N$ remains yet to be resolved $^{[45–47]}$.

The paper is organized as follows: First we introduce the supersymmetric $O(N)$ model (Sec. I) and derive the non-perturbative flow equation for the superpotential in LPA (Sec. II). We then solve this equation analytically in the large-$N$ limit (Sec. III C) and analyze the resulting fixed-point solutions (Sec. IV). We compute the universal scaling solutions and compare our re-
sults with those in the non-supersymmetric theory without fermions (Sec. IV). We close with a discussion of our results (Sec. V). Our conventions and a derivation of supersymmetric flow equations in superspace is found in the appendix.

II. SUPERSYMMETRY

In this section, we recall the definition of three-dimensional supersymmetric $O(N)$ models, which are built from $N$ real superfields

$$\Phi^i(x, \theta) = \phi^i + \bar{\psi}^i(x) + \frac{1}{2} \theta \theta F^i(x), \quad i = 1, \ldots, N. \quad (1)$$

Each component of the superfield contains a real scalar field, a two-component Majorana spinor field and a real auxiliary field, $\Phi^i \sim (\phi^i, \psi^i, F^i)$. We shall use a Majorana representation with imaginary $\gamma$-matrices $\{\gamma^\mu\} = \{\sigma_2, i\sigma_3, id_1\}$. Then the metric in $\{\gamma^\mu, \gamma^\nu\} = 2\delta^{\mu\nu}$ takes the form $\eta_{\mu\nu} = \text{diag}(1,-1,-1)$. A Majorana spinor is real in this representation and $\bar{\psi} = (i\bar{\psi}_2, -i\bar{\psi}_1)$. The supersymmetry variation of the superfield is generated by the supercharge $Q$ via $\delta_{\Phi^i} = i\bar{\psi}Q\Phi^i$, where the explicit form of the supercharge and further conventions are collected in appendix A. To construct a supersymmetric invariant action we note that the $F$-term in the expansion transforms under supersymmetry transformations into a spacetime divergence such that its spacetime integral is invariant.

In order to define an $O(N)$ symmetric, supersymmetric action we introduce the supercovariant derivatives

$$\mathbf{D} = \frac{\partial}{\partial \theta} + i \partial \theta \quad \text{and} \quad \bar{\mathbf{D}} = -\frac{\partial}{\partial \bar{\theta}} - i \bar{\partial} \bar{\theta}, \quad (2)$$

which anticommute with the supercharges and thus map superfields into superfields. Since the theory should be $O(N)$ invariant, the superpotential only depends on the invariant composite superfield $R \equiv \frac{1}{2} \Phi^i \Phi_i$. In component form, it reads

$$R = \bar{\varrho} + (\bar{\partial} \psi_i) \phi_i + \frac{1}{2} \bar{\theta} \theta \left( \phi^i F_i - \frac{1}{2} \bar{\psi}^j \psi_j \right), \quad (3)$$

where the quantity $\bar{\varrho} \equiv \frac{1}{2} \bar{\psi}^i \phi_i$ has been introduced. The starting point for further investigations will be the supersymmetric action

$$S = \int d^3x \left[ \frac{1}{2} \Phi^i \mathcal{D} \mathcal{D} \Phi_i + 2N W \left( \frac{R}{N} \right) \right] \bigg|_{\bar{\partial} \theta} \quad (4)$$

which contains a kinetic term with supercovariant Laplacian $\mathcal{D} \mathcal{D}$ as well as an interaction term, given by the superpotential $W$. We have already rescaled the fields and the superpotential with $N$. An expansion in component fields yields the Lagrangian density

$$\mathcal{L}_{\text{off}} = \frac{1}{2} \left( -\phi^i \bar{\partial} \phi_i - i \bar{\psi}^i \bar{\partial} \psi_i + F^2 \right) + W^\prime \left( \frac{\bar{\varrho}}{N} \right) \phi_i F^i - \frac{1}{2} W^\prime \left( \frac{\bar{\varrho}}{N} \right) \psi_i + W^\prime \left( \frac{\bar{\varrho}}{N} \right) \frac{(\bar{\psi}^j \phi_j)(\psi^i \phi_i)}{2N}. \quad (5)$$

where primes denote derivatives with respect to $\bar{\varrho}/N$. Eliminating the auxiliary field $F^i$ by its algebraic equation of motion, $F^i = -W^\prime(\bar{\varrho}/N)\phi_i$, yields the on-shell Lagrangian density

$$\mathcal{L}_{\text{on}} = -\frac{1}{2} \phi^i \bar{\partial} \phi_i - \frac{i}{2} \bar{\psi}^i \bar{\partial} \psi_i + \frac{1}{2} W^\prime \left( \frac{\bar{\varrho}}{N} \right) \psi^i \psi_i - \bar{\varrho} W^\prime \left( \frac{\bar{\varrho}}{N} \right) - W^\prime \left( \frac{\bar{\varrho}}{N} \right) \frac{1}{2N}. \quad (6)$$

From (6) we conclude that the potential for the bosonic field follows from the superpotential $W$ via

$$V(\bar{\varrho}) = \bar{\varrho} W^\prime \left( \frac{\bar{\varrho}}{N} \right) \quad (7)$$

Note that for a polynomial superpotential $W(\bar{\varrho}/N)$ which for large $\bar{\varrho}$ tends to $W \sim \bar{\varrho}^n$ we do not expect supersymmetry breaking in our non-perturbative renormalization group studies.

III. RENORMALIZATION GROUP

A. Supersymmetric flows

In order to analyze the phase transition and the low-energy behavior of supersymmetric sigma models we resort to Wilsonian renormalization group techniques. Specifically, we adopt the framework of the effective average action based on the infinitesimal integrating-out of degrees of freedom with momenta $q^2$ larger than some infrared momentum scale $k^2$. In consequence, the effective action becomes a scale-dependent effective action $\Gamma_k$ which interpolates between the microscopic action $S$ in the UV and the full quantum effective action in the IR, where $k \to 0$. The scale-dependence of $\Gamma_k$ is given by an exact functional differential equation 48

$$\partial_t \Gamma_k = \frac{1}{2} \text{Str} \left\{ \partial_t R_k \left( \Gamma_k^{(2)} + R_k \right)^{-1} \right\}, \quad (8)$$

where $t = \ln(k/\Lambda)$, $\text{Str}$ denotes the trace, $R_k(q^2)$ denotes the momentum cutoff. It obeys $R_k(q^2) \to 0$ for $k^2/q^2 \to 0$, $R_k(q^2) > 0$ for $q^2/k^2 \to 0$ and $R_k(q^2) \to \infty$ for $k \to \Lambda \to \infty$, where $k = \Lambda$ stands for the initial scale in the UV. The stability and convergence of the RG flow is controlled through adapted, optimized choices of the momentum cutoff 12 39 49. Furthermore, $\Gamma_k^{(2)}$ denotes the second functional derivative of $\Gamma_k$ with respect to the fields according to

$$\Gamma_k^{(2)} = \frac{\gamma}{\delta \phi^a} \Gamma_k \frac{\gamma}{\delta \phi^b}, \quad (9)$$

where $a, b$ summarize field components, internal and Lorentz indices as well as coordinates. Note that $\Psi$ is merely a collection of fields and not a superfield.
Following the construction in [27,31], it is essential that the regulator term \( \Delta S_k \) preserves both the \( O(N) \)-symmetry and supersymmetry of the classical theory. Being quadratic in the fields it should be the superspace integral of \( \Phi^i R_k(\mathcal{D}\mathcal{D})\partial_i \Phi^i \). Using the anticommutation relation \( \{D_k,\bar{D}_l\} = -2(\gamma^\mu)_{kl}\partial_\mu \) for the supercovariant derivatives, we have

\[
\left(\frac{1}{2} \mathcal{D}\mathcal{D}\right)^{2n} = (-\Box)^n, \tag{10}
\]

such that a supersymmetric and \( O(N) \)-invariant regulator term is the superspace integral of

\[
\Phi_i R_k(\mathcal{D}\mathcal{D})\Phi^i = \Phi_i \left( r_1(-\Box) - r_2(-\Box) \frac{\mathcal{D}\mathcal{D}}{2} \right) \Phi^i. \tag{11}
\]

Expressed in component fields, we find

\[
\Delta S_k = \frac{1}{2} \int (\phi, F) R_k^B (\phi) + \frac{1}{2} \int \bar{\psi} R_k^F \psi. \tag{12}
\]

In momentum space \( i\partial_\mu \) is replaced by \( p_\mu \) and the bosonic and fermionic momentum cutoffs \( R_k^B \) and \( R_k^F \) respectively are of the form

\[
R_k^B = \left( p^2 r_1 \frac{r_1}{r_2} \right) \otimes \mathbb{I}_N, \quad R_k^F = -\left( r_1 + r_2 p^2 \psi \right) \otimes \mathbb{I}_N. \tag{13}
\]

Note that the requirements of manifest supersymmetry imposes a link between the bosonic and fermionic momentum cutoffs, leaving two free functions \( r_1 \equiv r_1(p^2/k^2) \) and \( r_2 \equiv r_2(p^2/k^2) \) at our disposal. Such supersymmetric cutoffs have been introduced for the \( N = 1 \) model in two and three dimensions in [28,31].

There exist no Majorana fermions in three Euclidean spacetime dimensions. With respect to the supersymmetric \( O(N) \) model we could thus analytically continue the flow equation in Minkowski spacetime to imaginary time or alternatively just ignore the fact that the Majorana condition is not compatible with Lorentz invariance in Euclidean spacetime [43]. Both approaches lead to identical flow equations in Euclidean spacetime, cf. [31].

### B. Local potential approximation

Next we turn to the supersymmetric RG flow in the local potential approximation. Here, one keeps the leading order term in a superderivative expansion such that the effective action (with Lorentzian signature) reads

\[
\Gamma_k[\Phi] = \int d^3 x \left[ -\frac{1}{2} \Phi^i \mathcal{D}\mathcal{D} \Phi^i + 2N W_k \left( \frac{R}{N} \right) \right] \Big|_{\bar{\theta}} = \frac{1}{2} \int d^3 x \left( \partial_\mu \phi^i \partial^\mu \phi^i - i\bar{\psi}^i \gamma^\mu \psi_i + F^2 \right) + \int d^3 x \left( W_k^\mu (\bar{\psi}^i \partial^\mu \phi^i) (\psi^j \phi_j) \right), \tag{14}
\]

where the prime denotes the derivative with respect to \( \bar{\theta}/N \). The flow of the renormalized superpotential \( W_k(\bar{\theta}/N) \) in Euclidean space is obtained by projecting the flow \( \bar{\theta} \) onto the term linear in the auxiliary field \( F \) and performing a Wick rotation (see appendix [33] for its derivation in superspace). The function \( r_1 \) acts as IR regulator but not as UV-regulator, in contrast to \( r_2 \) which serves both as IR and UV regulator. Thus we use \( r_1 \) as regulator in what follows. Then we find

\[
\partial_k W_k = -\frac{1}{2} \int d^3 p \frac{1}{(2\pi)^3} \bar{\theta} r_2 \left( \frac{N - 1}{N} \frac{W_k'}{W_k} \left( \frac{1 + r_2}{N} W_k' + 2\bar{\theta}/N \right) \right) \left( 1 + 2\bar{\theta}/N \right) \left( W_k' + 2(\bar{\theta}/N)W_k'' \right). \tag{15}
\]

Similar to the bosonic \( O(N) \) model the flow receives contributions from the \( N - 1 \) Goldstone modes (the first term) and from the radial mode (second term).

Next we specify the function \( r_2(p^2/k^2) \). Following [12–14, 31] we choose the optimized regulator function

\[
r_2(p^2) = \left( \frac{k}{|p|} - 1 \right) \theta(k^2 - p^2). \tag{16}
\]

This choice implies \( \partial_k r_2 \) to vanish identically for \( p^2 > k^2 \), and the inverse propagators

\[
(1 + r_2)^2 p^2 + X = \begin{cases} p^2 + X & \text{for } p^2 > k^2 \\ k^2 + X & \text{for } p^2 < k^2 \end{cases}
\]

become flat (momentum independent) in the regime where the right-hand side of \( [15] \) is non-vanishing. In the LPA this is a solution to the general optimization condition of \([12,14]\) and is therefore expected to lead to improved convergence and stability of the RG flow. Equally important, the momentum integrals in \([15]\) can be performed analytically, leading to

\[
\partial_k W_k = -\frac{k^2}{8\pi^2} \left( 1 - \frac{1}{N} \right) \frac{W_k'}{k^2 + W_k^2} \left( 1 + \frac{k^2}{8\pi^2 N k^2 + \left( W_k' + 2(\bar{\theta}/N)W_k'' \right)^2} \right). \tag{17}
\]

With given initial condition \( W_k=\Lambda(\bar{\theta}/N) \equiv W(\bar{\theta}/N) \) at the UV scale \( \Lambda \) this flow equation uniquely determines the superpotential in the infrared limit \( k \to 0 \). For \( N = 1 \) it reduces to the three-dimensional Wess-Zumino model studied in [31].

In order to write the flow equation \([17]\) in a scale-invariant form it is convenient to define a dimensionless field variable \( \rho \) as well as a dimensionless superpotential \( w \) and a dimensionless scalar potential \( v \). The

\[\text{1 In preliminary studies we did include the regulator } r_1 \text{ and got almost identical results.}\]
canonical mass dimension of the fields and potentials are \( \bar{\rho} = d - 2 \), \( [V] = d \) and \( [W] = d - 1 \) in \( d \) spacetime dimensions. We therefore introduce the dimensionless quantities

\[
\rho = \frac{8\pi^2 \bar{\rho}}{N k} \quad \text{and} \quad w(\rho) = 8\pi^2 \frac{W(\frac{\bar{\rho}}{k})}{k^2}.
\]  

(18)

Note that we have also rescaled an irrelevant numerical factor into the potential and the fields. It is understood though this is not spelled out explicitly. Similarly, we define the dimensionless bosonic potential \( v \)

\[
v(\rho) = \frac{8\pi^2}{N} \left( \frac{W'(\frac{\bar{\rho}}{k})}{k} \right)^2 \equiv \rho w'^2(\rho),
\]

(19)

where (7) and (18) have been used. Thus, by substituting (7) and (18) into (17) we end up with the following flow equation for the dimensionless superpotential,

\[
\partial_t w - \rho w' + 2w = -\left(1 - \frac{1}{N}\right)w' - \frac{1}{N}(w' + 2\rho w'')^2.
\]

(20)

C. Large-\( N \) limit

In the large-\( N \) limit the Goldstone modes fully dominate the dynamics and the contribution of the radial mode becomes a subleading effect. It follows that the anomalous dimension of the Goldstone modes vanish, as no momentum-dependent two-point function exists that contribute to the running of the kinetic term of these modes to leading order in \( N \). This is a particular feature of the bosonic \( O(N) \) models \(^2\) and their supersymmetric extensions. Consequently, the LPA approximation becomes exact for \( N \to \infty \).

In this limit, the RG equation for the first derivative of the superpotential \( u(\rho) \equiv w'(\rho) \) becomes

\[
\partial_t u + \partial_{\rho} u \left[1 - \rho - u^2 f(u^2)\right] = -u
\]

(21)

with \( f(x) = (3 + x)/(1 + x)^2 \). We note that the second-order partial differential equation (20) has turned into a first-order one in this limit, which is solved analytically with the method of characteristics. The first characteristic reads \( u e^t = \text{const.} \) and the second one is

\[
\frac{\rho - 1}{u} - F(u) = \text{const.}
\]

(22)

with

\[
F(u) = \frac{u}{1 + u^2} + 2 \arctan u
\]

(23)

\(^2\) For example, Yukawa-type systems may have large anomalous dimensions in the large-\( N \) limit. \(^[20] \)

FIG. 1: Supersymmetric fixed point solutions \( \rho(u_c) \) for all fields \( \rho \) and all superfield potentials \( u_\ast \), color-coded by the free parameter \( c \) (both axes are rescaled as \( x \to \frac{x}{\sqrt{\tilde{F}(x)}} \) for display purposes). Thin lines are included to guide the eye, thick lines correspond to distinguished values for \( c \) \( (|c| = 0, c_L, c_P, c_M) \) as defined in main text.

and \( F'(u) = f(u^2) \). Altogether, we find

\[
\frac{\rho - 1}{u} - F(u) = G(ue^t)
\]

(24)

for all \( \rho \geq 0 \), where the function \( G(ue^t) \) is determined by the boundary conditions for \( u(\rho) \), imposed at the initial UV scale \( k = \Lambda \). The validity of the solution (24) is confirmed by direct insertion into (21). For completeness, we also give the RG equation for the bosonic potential. Using (19) and (22) we obtain

\[
\partial_t v + 3v - \rho v' = \left(v - \rho v'\right) \frac{\rho - v}{(\rho + v)^2}.
\]

(25)

In passing we note that up to minor modifications eq. (21) holds for general spacetime dimensions away from \( d = 3 \). The canonical mass dimension of \( u \) is one for all dimensions and the dependence on spacetime dimensionality, therefore, only enters via the field variable leading to the replacement of \( -\rho \) by \( (2 - d)\rho \) in (21). This modifies the second characteristic equation whose solution is expressed in terms of the hypergeometric function for arbitrary dimension \( d \neq 1 \). Below, we restrict ourselves to the case \( d = 3 \).
IV. FIXED POINTS

A. Supersymmetric fixed points

Fixed points are the scale-independent solutions of \( \frac{\partial}{\partial \rho} u = 0 \), i.e. solutions satisfying \( \partial \rho u = 0 \). Besides the Gaussian fixed-point solution \( u_* \equiv 0 \), non-trivial fixed points follow from \( \rho = 1 + H(u_*) + c u_* \), \( H(u_*) = u_* F(u_*) \),

\[
\rho = 1 + H(u_*) + c u_* \quad \text{and} \quad H(u_*) = u_* F(u_*) ,
\]

where \( F(u_*) \) is given by \( u_*^{(1)} \), then depends only on the real parameter \( c \). With \( |u*| \in [0, \infty) \) and for a fixed \( c \), \( F(u_*) \) identifies the range of achievable field values. Candidates for physical fixed points \( u_*(\rho) \) are those solutions which extend over all fields \( \rho \in [0, \infty] \). Fig. 1 and Fig. 2 display the entire set of solutions for \( c = 0 \) for all \( c \). Note that Fig. 1 shows the function \( \rho(u_*) \) whereas the relation \( u_*(\rho) \) is displayed in Fig. 2.

The space of solutions enjoys some internal symmetry. Since \( H(u_*) \) is an even function, solutions only depend on the absolute value of \( c \), i.e. any solution \( u_*(\rho) \) with parameter \( c \) is equivalent to the reflected solution \( -u_*(\rho) \) with parameter \( -c \). Both solutions lead to identical scalar potentials \( v_* = \rho u_*^2 \) and therefore we may restrict our discussion to \( c \geq 0 \).

We now discuss \( F(u_*) \) in more detail. All curves pass through

\[
(\rho, u_*) = (1, 0)
\]

which follows immediately from \( F(u_*) = 0 \) due to \( H(0) = 0 \) as can be seen from Fig. 2. The fixed point solutions fall into two distinct classes, and solutions in the same class show the same global behavior. Depending on the value of \( c \) the solution \( u_* \) is either defined for all real \( \rho \) or it has a turning point at \( |\rho_*| < \infty \) and is only defined for \( \rho \in [\rho_*, \infty) \). In the latter case the solution has two branches bifurcating at \( \rho = \rho_* \). The value of \( \rho_* \) will be determined below.

Next we discuss some limiting cases of interest. For small \( u_* \) we conclude from (26) that

\[
\rho - 1 = c u_* + 3 u_*^2 + O(u_*^3)
\]

Hence, the potential is analytical in \( \rho - 1 \) in the vicinity of \( \rho = 1 \) for all \( c \) except for \( c = 0 \) where it becomes non-analytical with \( u_* \propto \sqrt{\rho - 1} \). Eq. (28) implies that all fixed-point solutions have one simple zero at \( \rho = 1 \) with finite \( u'_*(1) \) except for \( c = 0 \) where \( u'_*(1) \) diverges. Consequently, the scalar fixed-point potentials \( v_* = \rho u_*^2 \) possess two minima at

\[
\rho = 0 \quad \text{and} \quad \rho = 1 ,
\]

the first one being a simple zero. The second minimum is a double zero for \( c \neq 0 \) and a simple zero for \( c = 0 \).
In the large-$u_*$ limit of (26), we find
\[ \rho = \pi |u_*| + c u_* + O(1/u_*^2). \] (30)
Thus the asymptotic behavior of $u_*$ is given by
\[
\begin{align*}
 u_* &= \frac{\rho}{c + \pi} + \text{subleading} \quad (u_* > 0), \\
 u_* &= \frac{\rho}{c - \pi} + \text{subleading} \quad (u_* < 0). 
\end{align*}
\] (31)

If $|c| > c_P$, with
\[ c_P = \pi, \] (32)
the expansions extend towards $\rho \to \pm \infty$, respectively. Together with the boundedness of $H(u_*)$ we conclude that $u_*(\rho)$ is defined for all real $\rho$. The expansions correspond to asymptotically large fields $\rho \gg 1$ in the physical regime. At $|c| = c_P$ the leading term in (30) vanishes and, depending on the sign of $c$, one of the asymptotic solutions is replaced by $u_* \sim \rho^{-1/2}$ thus corresponding to a small field regime $\rho \ll 1$. For $|c| < c_P$ both expansions extend towards $\rho \to +\infty$. We conclude that $u_*$ has, simultaneously, two asymptotic expansions for large positive $\rho$. This implies that $v_*$ displays a loop consisting of two branches $v_<$ and $v_>$ which coincide at $\rho = \infty$ and possibly at some $\rho = \rho_0 < \infty$ where $u_*$ has infinite slope. The latter condition determines the turning point $\rho_*$ as the simultaneous solution of
\[ \rho_* = \frac{1 - u_*^2}{(1 + u_*^2)^2}. \] (33)

together with (26), leading to
\[ |c| = \frac{1}{|u_*|} \left( \frac{u_*^2(3 + u_*^2)}{1 + u_*^2} + H(u_*) \right), \] (34)
where $u_* = u_*(\rho_*)$. The degenerate solutions extend over the whole physical regime $\rho \geq 0$, provided that $\rho_0 \leq 0$. From (32) it follows that the equal sign holds for $u_*^2 = 1$ leading with (34) to $|c| = c_L$, where
\[ c_L = \frac{1}{2}(\pi + 3) \approx 3.071. \] (35)

For $|c| = c_L$, both $u_<$ and $u_>$ have infinite slope at vanishing field with the non-analytical behavior
\[ \frac{du_*}{d\rho} = \pm \frac{1}{\sqrt{\rho}} + \text{subleading} \] (36)
and $u_* = \mp 1$ for $c = \pm c_L$ (see Fig. 3 left panel). In contrast, for $c_L < |c| < c_P$, the behavior at vanishing field is analytic. The turning point (33) exists for small $0 \leq |c| \leq c_M$ as long as $d^2\rho/du_*^2$ does not vanish, which happens at $u_*^2 = 3$ leading with (34) to $|c| = c_M$, where
\[ c_M = 2 \left( \frac{\pi}{3} + \frac{5\sqrt{3}}{16} \right) \approx 3.177. \] (37)

We note that $c_P < c_M$ and conclude that the fixed point solutions in the parameter regime $c_P \leq |c| < c_M$ are single-valued in the physical regime but multi-valued in the non-physical regime $\rho < 0$. For all $c_M \leq |c|$, fixed point solutions are single-valued on the entire real axis. In Fig. 3, right panel the scalar fixed point potential $v_*$ for different values of $c$ is displayed.
B. Exactly marginal coupling

Next we discuss the physical meaning of the parameter $c$. To this end we employ the polynomial expansion of the RG-time dependent superpotential $u(t, \rho)$ which satisfies the flow equation \((21)\). For a typical initial condition $u_{A} = \tau_{1}(\rho - \rho_{0})$ there always exists a node $\rho_{0}(t)$ around which we can perform a Taylor expansion:

$$u(t, \rho) = \sum_{n=1}^{\infty} \frac{1}{n!} \tau_{n}(t) (\rho - \rho_{0}(t))^{n}.$$ \tag{38}

Inserting this ansatz into the flow equation \((21)\) we read off the flow equations for $\rho_{0}$ and the couplings $\tau_{n}$ entering the Taylor expansion

\begin{align*}
\partial_{t} \rho_{0} &= 1 - \rho_{0} \quad \text{(39)} \\
\partial_{t} \tau_{1} &= 0 \quad \text{(40)} \\
\partial_{t} \tau_{2} &= 6 \tau_{1}^{3} + \tau_{2} \quad \text{(41)}
\end{align*}

and similarly to higher order. Several comments are in order at this point. Firstly, the running of the vev $\rho_{0}(t)$ is independent of all the other local couplings. This property is typical for a supersymmetric flow and has previously been observed in \cite{29, 31}. The fixed point is obtained for $\rho_{0} = 1$. Secondly, the system of algebraic equations describing the $t$-independent fixed point couplings can be solved recursively. This leads to fixed point couplings $\tau_{n}(\tau_{1})$ for all $n \geq 2$ as functions of $\tau_{1}$. Inserting \((38)\) into the expansion of the scalar field potential $v = \rho u^{2} = \sum_{n=2}^{\infty} \lambda_{n}/n! (\rho - \rho_{0})^{n}$ and evaluating it on the fixed point leads to the fixed point values

\begin{align*}
\lambda_{2} &= 2 \tau_{1}^{2} \quad \text{(42)} \\
\lambda_{3} &= 6 \tau_{1}^{2} (1 - 6 \tau_{1}^{2}) \quad \text{(43)} \\
\lambda_{4} &= -24 \tau_{1}^{4} (1 - 45 \tau_{1}^{4}) \quad \text{(44)}
\end{align*}

and similarly to higher order. Clearly, the weak (strong) coupling regimes correspond to small (large) $\lambda_{2}$ and hence small (large) $\tau_{1}$ respectively. Also, on the level of the scalar field potential the critical behavior is independent of the sign of $\tau_{1}$. Finally, and most importantly, the coupling $\tau_{1}$ remains un-renormalized under the supersymmetric RG flow \((40)\). Therefore $\tau_{1}$ corresponds to an exactly marginal coupling, and fixed points can be classified according to the value of the linear (dimensionless) superfield interaction $\tau_{1}$ which relates to the free parameter $c$ in the analytical solution \((26)\) as

$$c = \frac{1}{\tau_{1}}.$$ \tag{45}

This relation can be shown by inserting expansion \((38)\) into the fixed point equation \((20)\). The presence of the exactly marginal coupling $\tau_{1}$ explains the existence of a line of fixed points.

C. Line of fixed points

In summary, the following picture has emerged. Fixed point solutions are characterized by the dimensionless linear superfield coupling $\tau_{1} = 1/c$ in the vicinity of the node $\rho_{0} \neq 0$. In the weakly coupled regime

$$c_{P} \leq |c|$$ \tag{46}

a unique fixed point solution exists covering the whole physical domain $\rho \geq 0$. This includes the Gaussian fixed point $\tau_{1} = 0$. In the intermediate coupling regime

$$c_{L} \leq |c| < c_{P}$$ \tag{47}

two separate fixed point solutions $u_{<}$ and $u_{>}$ exist. The former solution has a node at $\rho_{0} = 1$ whereas the other solution has no node, see Fig. 3 left panel. Therefore, the corresponding scalar field potentials $v_{<}(v_{>})$ have two minima at \((29)\) (one minimum at $\rho = 0$). Both are analytical functions of $\rho$ in the vicinity of their global minima. For $|c| = c_{L}$, the potential becomes non-analytical for either of them at $\rho = 0$ in a manner reminiscent of the Bardeen-Moshe-Bander phenomenon in the purely scalar theory \cite{7}. In the strong coupling regime

$$|c| < c_{L}$$ \tag{48}

the theory becomes so strongly coupled that $du/d\rho_{0}$ diverges in the physical regime, and hence no fixed point solution exists which extends over all fields. Therefore, the supersymmetric $O(N)$ model displays a line of fixed points which bifurcates at $|c| = c_{P}$ into two fixed points, and then terminates at $|c| = c_{L}$.

Finally we note that the solution with $c = 0$ is closely linked to the Wilson-Fisher fixed point in the purely bosonic model \cite{37–39}. The precise relation is discussed in Sec. V C below.

V. UNIVERSALITY

A. Critical exponents

Fixed point solutions are characterized by universal critical scaling exponents. The exponents can be deduced from the RG equations in several ways. Within a polynomial approximation up to order $n$, we expand $u(\rho) = \sum_{i=1}^{n} b_{i}(\rho - \rho_{0})^{i}/i!$ in terms of the $n + 1$ couplings $b_{i}(t)$. From their beta-functions $\beta_{i} \equiv \partial_{t} b_{i}$, the universal exponents follow as the negative of the eigenvalues $\theta^{i}$ of their stability matrix $B^{.j}_{.i} = \partial \beta_{i}/\partial b_{j}|_{b_{i}=b_{j}}$, as $B v^{i} = -\theta^{i} v^{i}$ with eigenvectors $v^{i}$. Using the flow equation, we find

$$\theta = -1, 0, 1, 2, 3, \cdots$$ \tag{49}

both numerically and analytically. In fact, the LPA approximation has become exact in the large-$N$ limit, and
hence the correct scaling exponents are achieved to every order in the polynomial approximation. We note that this analysis relies on local information of the RG flow in the vicinity of \( u = 0 \), showing that the scaling (49) is achieved mathematically for all \( 0 < |c| < \infty \). Physically, however, the analysis is not sensitive to the global behavior of the solution, and consequently cannot detect that \( |c| = c_2 \) denotes a physical endpoint. Also, the case \( c = 0 \) requires special care as an analytical expansion about \( u = 0 \) is no longer applicable.

### B. Eigenperturbations

Interestingly, the critical exponents and eigenperturbations can also be calculated analytically without resorting to a polynomial expansion. To that end, we consider small fluctuations \( \delta u \) about the fixed-point superpotential such that \( u(t, \rho) = u_*(\rho) + \delta u(t, \rho) \). Linearizing the flow equation in \( \delta u \) leads to the fluctuation equation

\[
\partial_t \delta u = \frac{u_*}{u_*^\prime} \left( \partial_\rho - \frac{(u_* u_*^\prime)^\prime}{u_*} \right) \delta u, \tag{50}
\]

where primes denote a derivative with respect to the function’s argument. Since the right-hand side is independent of \( t \), the differential equation (50) can be factorized via separation of variables \( \delta u(t, \rho) = f(t)g(\rho) \) with

\[
\begin{align*}
(\ln f)^\prime &= \theta \\
(\ln g)^\prime &= \theta (\ln u_*)^\prime + (\ln u_* u_*^\prime)^\prime,
\end{align*}
\]

where \( \theta \) denotes the eigenvalue. Integration leads to the exact solution for the linear perturbation of the fixed point superpotential

\[
\delta u = Ce^{\theta t} u_*^{\theta + 1} u_*^\prime. \tag{52}
\]

The allowed range of values for the exponents \( \theta \) is determined using regularity conditions for the eigenperturbations. To that end, we recall that the fixed point potential \( u_* \) grows linearly with the field for large \( \rho \), see (30), and hence \( \delta u \sim e^{\theta t} \rho^{\theta + 1} \). Furthermore, in the vicinity of the node we have (28), which for \( c \neq 0 \) leads to a finite \( u^\prime \) (meaning \( 0 < u^\prime < \infty \)). We thus find

\[
\delta u \sim e^{\theta t} (\rho - 1)^{\theta + 1}. \tag{53}
\]

Regularity of the perturbations requires non-negative integer values for the exponent \( \theta + 1 \), reproducing (49).

Note that this line of reasoning assumes analyticity of the perturbation at the node which holds for all \( c \neq 0 \). For \( c = 0 \), \( u_* \) is non-analytical at (27) but \( u_*^2 \) instead is analytical and has a simple zero with finite \( (u_*^2)^\prime|_{u_*=0} \). Therefore we use (52) to relate the (regular) fluctuations of \( u^2 \) to \( u_*^2 \), leading to

\[
\delta u^2 = Ce^{\theta t} (u_*^2)^{\frac{1}{2}(\theta + 1)} (u_*^2)^\prime. \tag{54}
\]

Again, analyticity implies that the exponent \((\theta + 1)/2\) is a non-negative integer

\[
\theta = -1, 1, 3, 5, 7, \ldots \tag{55}
\]

Here we recognize the universal critical exponents of the 3d spherical model [19]. We stress, however, that this solution is not a proper fixed point solution in the usual sense because it is limited to field values with \( \rho \geq 1 \).

Finally we extend the analysis of linear perturbations to those of the function \( u^2 \) and the scalar potential \( v = \rho u^2 \). We begin with \( u^2 = u_*^2 + \delta u^2 \). An analytical solution is found by using the identity \( \delta u^2 = 2 u_* \delta u + \delta u^2 \) together with (52), leading to

\[
\delta u^2 = 2Ce^{\theta t} u_*^{\theta + 2} u_*^\prime. \tag{56}
\]

Note that the degree in \( u_* \) has increased by one unit. Employing the same reasoning as above for \( c \neq 0 \), we conclude that the set of available eigenvalues is

\[
\theta = -2, -1, 0, 1, 2, 3, \ldots \tag{57}
\]

Physically, the appearance of the eigenmode with eigenvalue \(-2\) is due to the mass term squared, a term which on dimensional grounds is available in \( u^2 \) but not in \( u \).

Finally, using (25), (56) and (21), the linear eigenperturbations about the scalar potential \( v(t, \rho) = v_* + \delta v(t, \rho) \) are found as

\[
\delta v = 2Ce^{\theta t} u_*^{\theta + 2} \{ u_* + u_*^\prime[1 - u_*^2 f(u_*^2)] \}. \tag{58}
\]

Close to \( u_* = 0 \), the term in square brackets reduces to 1, and the curly bracket becomes \( u_*^\prime \) which is finite at \( u_* = 0 \). Therefore regularity of eigenperturbations again implies (57). In a non-supersymmetric scalar theory the potential is not constrained to be of the product form (49) and an additional eigenvalue \(-3\) becomes available related to redundant shifts of the potential.

We conclude that supersymmetry is responsible for the absence of the redundant eigenvalue \(-3\) in the scalar potential, and for relating its two relevant eigendirections with eigenvalues \(-1\) and \(-2\) with the sole relevant eigendirection with eigenvalue \(-1\) of the derivative of the superpotential.

### C. Wilson-Fisher fixed point

It is interesting to clarify how the supersymmetric model and its fixed points fall back onto those of the 3d non-supersymmetric scalar theory in the same approximation [37,39]. To that end, we consider the 4d supersymmetric \( O(N) \) at finite temperature. The temperature is implemented using the imaginary time formalism which on the level of the flow equation amounts to the replacements

\[
\int_{-\infty}^{\infty} \frac{dq_0}{2\pi} f(q_0) \rightarrow T \sum_{n=-\infty}^{\infty} f(q_0 = 2\pi c_n T). \tag{59}
\]
where \( \partial_t z = -2z + \rho z' - \frac{1}{(1+z)^2} z' \) \( \rho \) (60)

where \( z \) is related to the scalar field potential by \( v(\rho) = \rho z(\rho) \). The key difference to the supersymmetric system studied previously is that the function \( z \) is no longer constrained to be the square of a superpotential derivative \( w' \). Relaxing this constraint allows for an additional fixed point solution, which follows from integrating (60) analytically. The general solution reads

\[
\frac{\rho - 1}{\sqrt{z}} - \frac{\sqrt{z}}{1 + z} - 2 \arctan \sqrt{z} = B(\rho e^{2t})
\]

(61)

where \( B(\rho e^{2t}) \) is fixed through initial conditions. The solution for negative \( z \) is found by analytical continuation. In particular, (60) has a Wilson-Fisher fixed point solution \( z_0 \neq 0 \) with \( z(\rho = 1) = 0 \) corresponding to \( B = 0 \). The solution extends over all \( \rho \) with one unstable direction, see Fig. 4. The eigenperturbations \( z = z_0 + \delta z \) are found analytically leading to (64) with the replacements \( \delta \mu \rightarrow \delta z \) and \( \mu^2 \rightarrow z_0 \). Hence, the universal eigenvalues are identical and given by (55).

The similarities and differences between the Wilson-Fisher fixed point solution of the purely scalar theory and the \( c = 0 \) ‘would-be’ Wilson-Fisher fixed point of the supersymmetric partner theory can also be appreciated from the behavior at small and large fields. In fact, for \( \rho \geq 1 \), \( z_0(\rho) \) is positive and related to the real superpotential by

\[
z_0(\rho) = w_0'(\rho)^2.
\]

(62)

In turn, \( z_0(\rho) \) is negative for all \( \rho < 1 \). Interestingly, this solution is still visible in the supersymmetric theory where it corresponds to a purely imaginary “superpotential” with

\[
w_0'(\rho) = \pm i \sqrt{-z_0(\rho)}.
\]

(63)

Hence, provided that a purely imaginary superpotential is meaningful in the supersymmetric theory, the \( c = 0 \) solution can be extended to a valid supersymmetric Wilson-Fisher fixed point for all \( \rho \). However, the structure of the Lagrangian imposed by supersymmetry implies that the field-dependent fermion mass term is proportional to \( w_0' \) and the Yukawa-type fermion-boson interaction proportional to \( w_0'' \) all become purely imaginary. Most importantly, a purely imaginary \( w_0' \) for small fields implies that the scalar potential obeys \( v_s(\rho) = \rho w_0'^2 < 0 \) for all fields within \( 0 < \rho < 1 \). Unbroken global supersymmetry requires that the dimensionful \( V_0(\bar{\varphi}) \) remains positive for all fields and scales. In the infrared limit \( k \rightarrow 0 \), re-inserting powers of \( k \), the dimensionful potential approaches \( V(\bar{\varphi}) = 64\pi^2 \bar{\varphi}^3/N^2 \geq 0 \). Hence, our results state that this potential can be approached arbitrarily close from within a phase with \( O(N) \) symmetry and global supersymmetry.

### VI. CONCLUSIONS

We have studied fixed points of supersymmetric \( O(N) \) symmetric Wess-Zumino models in the limit of many components \( N \rightarrow \infty \) in three dimensions with the help of the renormalization group. We have solved the theory analytically, showing that it displays a line of nontrivial fixed points solely parametrized by the exactly marginal linear superfield coupling. The fixed points are non-Gaussian, yet they display Gaussian exponents similar to the line of fixed points observed in the bosonic \( (\phi^2)^3 \) theory. The line of fixed points contains the Gaussian fixed point and therefore all fixed-points are continuously linked to the Gaussian one. With increasing superfield coupling, the line of fixed points bifurcates into two fixed point solutions, both of which terminate at a critical coupling (15) below which no fixed point solutions exist which extends over all physical fields. One of these solutions has its minimum at \( \rho_0 = 0 \) the other at \( \rho_0 \neq 0 \).
Interestingly, remnants of the non-Gaussian scaling exponents of the 3d spherical model [35] become visible for asymptotically large superfield coupling. However, the fixed point solution does not extend over all fields in the supersymmetric case, except if the superfield potential becomes purely imaginary for small fields.

From a structural point of view, the main impact of global supersymmetry on the critical behavior in comparison with the purely scalar theory is summarized as follows. Firstly, for unbroken global supersymmetry the scalar potential has its minimum at vanishing field. Hence the irrelevant eigenmode with eigenvalue $-3$ corresponding to overall shifts in the potential is absent from the supersymmetric eigenvalue spectrum. Secondly, the quartic and sextic coupling of the scalar potential are no longer independent. Hence, in the supersymmetric theory criticality is achieved by tuning only one parameter as opposed to the tuning of two parameters in the corresponding purely bosonic theory. This is reflected in the sole negative eigenvalue for $u$ as opposed to the two negative eigenvalues for both $u^2$ and $v$. Finally, at the coupling $|c| = c_L$ [35] the supersymmetric model shares similarities with the Bardeen-Moshe-Bander phenomenon in the bosonic theory [3]. The logarithmic singularity observed in [3] is superseded by a square-root behavior in the supersymmetric case, a difference which can be traced back to the underlying regularizations.

The fixed point solutions discussed in this paper describe the phase transition for the breaking of the $O(N)$ symmetry. Analyzing the pattern of symmetry breaking and the phase transition between symmetric and broken phases in more detail, and relating our findings with earlier studies based on gap equations is deferred to an upcoming publication. Furthermore, stepping back to finite $N$ we expect modifications to the above picture, both within the local potential approximation studied here and to higher order in the derivative expansion. For example, it is known that the $N = 1$ model displays a superscaling relation linking the unstable direction with the anomalous dimension [28] [31], a behaviour which is quite different from the Ising universality class [24]. It will thus be interesting to see how these patterns generalize for supersymmetric $O(N)$ models with generic $N$.

Appendix A: Conventions

Relevant symmetry relations and Fierz identities for Majorana spinors are $\tilde{\Psi} \chi = \tilde{\chi} \Psi$, $\Psi \gamma^\mu \chi = -\chi \gamma^\mu \Psi$ and $\bar{\theta}_k \theta_l = -\frac{1}{2} (\bar{\theta} \theta) \delta_{kl}$. One of the main features of the action is its invariance under supersymmetry transformations. The latter are characterized by the supersymmetry variations $\delta_s \Phi^i$, generated by the $\mathcal{N} = 1$ fermionic generator $Q$. We have

$$\delta_s \Phi^i(x) = i \bar{c}_k Q_k \Phi^i(x) \text{ with } Q_k = -i \partial_{\bar{\theta}_k} - \gamma^\mu \partial_\mu.$$

Thus, (A1) leads to the supersymmetry variations

$$\delta \phi^i = \bar{c} \psi^i, \quad \delta \bar{\psi}^i = (F^i + i \partial \phi^i) c \quad \text{and} \quad \delta F^i = i \bar{c} \partial \bar{\psi}^i$$

of the component fields. The anticommuting sector of the superalgebra is given by the anticommutator of two supercharges

$$\{Q_k, Q_l\} = 2 \gamma^\mu_{kl} \partial_\mu.$$

Appendix B: Superspace

Following [27] we consider the action of the three-dimensional supersymmetric $O(N)$ model in the local potential approximation

$$\Gamma_k[\Phi^i] = \int d^3 x \frac{d \theta_1 d \theta_2}{2i} \left( \frac{1}{2} \Phi^i K \Phi_i + 2 W_k(R) \right),$$

where $R = \frac{1}{2} \Phi^i \Phi_i$, $K = \frac{1}{2} (\bar{D} D - D \bar{D})$ and $i = 1, \ldots, N$. We derive the flow equation in the superspace $\mathbb{R}^{3|2}$ with coordinates $z = (x, \theta_1, \theta_2)$. Furthermore, we introduce the abbreviation $\int dz \equiv \int d^3 x d \theta_1 d \theta_2 / (2i)$. In Minkowski spacetime [31], the Wetterich equation in superspace may be written in the form

$$\partial_t \Gamma_k = \frac{i}{2} \int dz' dz (\partial_t R_k)_{mn}(z, z') (G_k)_{nm}(z', z), \quad t = \ln(k^2 / \Lambda^2),$$

where $(R_k)_{mn}$ represents a supersymmetric regulator term and $(G_k)_{nm}$ the connected Green’s function. According to [27] [31], we now choose a general regulator term quadratic in the superfields $\Phi^i$ and diagonal with respect to the
field indices:

\[ \Delta S_k = \frac{1}{2} \int dz \Phi^i R_{i,j}(D, D) \Phi^j = \frac{1}{2} \int dz \Phi^i \left(2r_1(-\partial^2_{\theta}, k)\delta_{ij} - r_2(-\partial^2_{\bar{\theta}}, k)K\delta_{ij}\right) \Phi^j. \]  

(B3)

Notice that this regulator conserves both the \(O(N)\) symmetry and supersymmetry. The functional derivative with respect to a superfield is chosen according to the conventions \( \frac{\delta}{\delta \Phi^i(z)} = \delta^i_j \) with \( \frac{\delta \Phi^i(z)}{\delta \Phi^m(z')} = 2i \delta^i_j \delta(x - \hat{x}) \delta(\theta_2 - \hat{\theta}_2) \delta(\theta_1 - \hat{\theta}_1) \equiv \delta^i_j \delta(z - \hat{z}). \) Thus, the second functional derivative of the effective average action with respect to the superfields reads

\[ \Gamma^{(2)}_{k,nm}(z, z') = \frac{\partial}{\partial \Phi^m(z)} \Gamma^{(2)}_{k,nm}(z, z'). \]

Similarly, the second functional derivative \( \Delta S^{(2)}_k(z, z') \) of the regulator term is given by

\[ (R_k)_{nm}(z, z') = [2r_1 - r_2 K](z) \delta_{nm}(z - z'). \]  

(B5)

Now we assume the superfields to be constant, i.e. \( \partial_x \Phi^i(x, \theta) = 0 \), such that the regulator functions as well as the wave operator may be simply written in momentum space. However, note that the wave operator \( K \) still contains derivatives with respect to the Grassmann coordinates and thus acts on the adjacent delta functions. Hence, the flow of the effective average action may be written as

\[ \partial_t \Gamma_k = \frac{i}{2} \int dz dz' \left( \partial_t (R_k)_{nm}(z, z') \Gamma^{(2)}_{k,nm}(z, z') + (R_k)_{nm}^{-1}(z', z) \right) \]

\[ = \frac{i}{2} \int d^3x \frac{d\theta_1 d\theta_2 d\bar{\theta}_1 d\bar{\theta}_2}{2 \pi} \int \frac{d^3p}{(2\pi)^3} (2\partial_t r_1 - \partial_t r_2 K)(p, \theta_1, \theta_2) \delta_{nm} 2i \delta(\theta_2 - \theta_2') \delta(\theta_1 - \theta_1') \times \]

\[ \left[ (-h K(p, \theta_1, \theta_2) + 2\mathcal{W}\delta_{nm} + 2\mathcal{W}'\Phi_n \Phi_m) \right]^{-1} 2i \delta(\theta_2' - \theta_2) \delta(\theta_1' - \theta_1). \]  

(B6)

We have thereby introduced the notation \( \mathcal{W}'(R) \equiv \mathcal{W}'(R) + r_1, h \equiv 1 + r_2 \). The inverse of the \( N \times N \)-matrix

\[ (M)^{nm}_1 = (-h K + 2\mathcal{W}) \delta_{nm} + 2\mathcal{W}'\Phi_n \Phi_m \]  

(B7)

is given by

\[ (M)^{nm} = \frac{(-h K + 2\mathcal{W})\delta_{nm} + 2\mathcal{W}'(\Phi^2 \delta_{nm} - \Phi_n \Phi_m)}{4(h^2p^2 + \mathcal{W}(\mathcal{W} + 2\mathcal{W}'R) - hK(\mathcal{W} + \mathcal{W}'R))}. \]

(B8)

where we have used the relation \( K^2(p) = 4p^2 \) resulting from the action of \( K(p) = -\partial_\theta\bar{\theta}_\bar{\theta} - (\partial_\theta \theta \bar{\theta}) - (\bar{\theta} \bar{\theta} \theta) - p^2(\bar{\theta} \theta) \) on an arbitrary superfield. In order to eliminate the wave operator \( K \) in the denominator of \( \text{(B8)} \), we multiply both the numerator and the denominator with \( [(h^2p^2 + \mathcal{W}(\mathcal{W} + 2\mathcal{W}'R)) + hK(\mathcal{W} + \mathcal{W}'R)] \) and use again \( K^2(p) = 4p^2 \). Thus we get

\[ (M)^{nm} = \frac{-2h^2 p^2 (\delta_{nm} \mathcal{W}' + \mathcal{W}'' \Phi_n \Phi_m) - \mathcal{W}'(\mathcal{W}' + 2\mathcal{W}'R)(\mathcal{W}'' \delta_{nm} + \mathcal{W}''(\Phi^2 \delta_{nm} - \Phi_n \Phi_m))}{4(h^2p^2 - \mathcal{W}^2)(h^2p^2 - (\mathcal{W} + 2\mathcal{W}'R)^2)} \]

\[ - hK \frac{\delta_{nm}(h^2p^2 - \mathcal{W}^2) - 2\mathcal{W}'(\mathcal{W}' + \mathcal{W}'R)(\Phi^2 \delta_{nm} - \Phi_n \Phi_m))}{4(h^2p^2 - \mathcal{W}^2)(h^2p^2 - (\mathcal{W} + 2\mathcal{W}'R)^2)} \]

\[ \equiv \frac{-2f_{nm} - hK g_{nm}}{\mathcal{R}} \]  

(B9)

with \( \mathcal{R} = 4(h^2p^2 - \mathcal{W}^2)(h^2p^2 - (\mathcal{W} + 2\mathcal{W}'R)^2) \). For

\[ (G_k)_{nm}(p, \theta'_1 - \theta_1, \theta'_2 - \theta_2) = (M)^{nm}(p, \theta'_1, \theta'_2) 2i \delta(\theta'_2 - \theta_2) \delta(\theta'_1 - \theta_1) \]  

(B10)

to be the Green’s function it has to fulfill the defining relation

\[ \int dz (G_k)_{nm}(z, \bar{z})(\Gamma^{(2)}_{k} + R_k)_{np}(z, z') = \delta(\bar{z} - z') \delta_{nm}. \]  

(B11)

This can be shown by directly inserting the explicit expressions on the left hand side and working out the contributions to different orders in \( K \).
The flow equation is calculated by inserting the regulator \( (B5) \) as well as the propagator \( (B10) \) into eq. \( (B6) \). Note that the regulator \( (R_k)_{mn} \propto \delta_{mn} \) is diagonal with respect to the field indices. Hence, we simply have evaluate the trace over the Green’s function \( (G_k)_{mn} \). This yields

\[
\partial_t \Gamma_k = \frac{i}{2} \int d^3 p (2\pi)^3 \left( (\epsilon_k r_1 - \epsilon_k r_2 K)(p, \theta_1, \theta_2) \gamma (\theta_1 - \theta_2) \right.
\]

\[
\times \left. \left( -2h^2 p^2 (NW + 2W' R) - W'(W' + 2W'' R)(NW + 2(N - 1)W'' R) \right) \right) \delta (\theta_2) \delta (\theta_1 - \theta_1'). \tag{B12}
\]

Now, only terms linear in \( K \) contribute to the flow of \( \Gamma_k \) after having integrated out the Grassmann variables. Those contributing terms lead to a multiplying factor of \( 2i \). Thus the flow equation \( (B12) \) simplifies to

\[
\partial_t \Gamma_k = -i \int d^3 x \partial_t q_1 \partial_q W_k(R)
\]

\[
= \frac{1}{2} \int d^3 x \partial_t q_1 \partial_q W_k(R)
\]

\[
= \frac{1}{2} \int d^3 p (2\pi)^3 \left( (N - 1) \frac{\partial r_1 h - \partial r_2 W'}{h^2 p^2 - W'^2} + \frac{\partial r_1 h - \partial r_2 (W' + 2W'' R)}{h^2 p^2 - (W' + 2W'' R)^2} \right). \tag{B13}
\]

Performing a Wick rotation of the zeroth component of the momentum, i.e. \( p^0 \to i\gamma^0, p^2 \to -p_E^2 \), we obtain the Euclidean version of the flow equation \( (B13) \). Thus, the resulting flow equation in superspace reads

\[
\int d^3 q \partial_q W_k(R) = \frac{1}{2} \int d^3 p \left( (N - 1) \frac{\partial r_1 h - \partial r_2 W'}{h^2 p_E^2 + W'^2} + \frac{\partial r_1 h - \partial r_2 (W' + 2W'' R)}{h^2 p_E^2 + (W' + 2W'' R)^2} \right). \tag{B14}
\]

Notice, that the truncation \( (14) \) involved a superpotential of the form \( 2W_k(R/N) \) instead of \( 2W_k(R) \). The corresponding flow equation may be easily derived from the above result by performing the substitution \( W_k(R) \to NW_k(R/N) \) in \( (B14) \). This yields the final result

\[
\int d^3 q \partial_q W_k(R/N) = \frac{1}{2} \int d^3 p \left( (N - 1) \frac{\partial r_1 h - \partial r_2 W'}{h^2 p_E^2 + W'^2} + \frac{1}{N} \frac{\partial r_1 h - \partial r_2 (W' + 2W'' R/N)}{h^2 p_E^2 + (W' + 2W'' R/N)^2} \right). \tag{B15}
\]
