Conversion of anilines to chiral benzylic amines via formal one-carbon insertion into aromatic C–N bonds

Lei Li¹, Min Yang², Qiuqin He¹ & Renhua Fan¹✉

Insertion of atoms into aromatic carbon-nitrogen bonds is an appealing method for the synthesis of nitrogen-containing molecules and it has the advantage of the availability and abundance of anilines. However, the direct cleavage of aromatic carbon-nitrogen bonds is challenging due to the particularly inert and stable nature of these bonds. Here we report a formal, enantioselective one-carbon insertion into an aromatic carbon-nitrogen bond via an aromaticity disassembly-reconstruction process to directly convert anilines to chiral α-branched benzylic amines. The process involves oxidative dearomatization of para-substituted anilines, chiral sulfur ylide-mediated asymmetric aziridination, and subsequent rearrangement. Chiral sulfur ylides serve as one-carbon insertion units.

insertion of atoms into chemical bonds is an attractive transformation of organic molecules because it leads to the simultaneous formation of two new chemical bonds. In recent decades, significant progress has been made in transition-metal-catalyzed insertion of atoms into unreactive chemical bonds such as carbon–carbon\(^1\), carbon–cyano\(^1\), and aliphatic carbon–nitrogen bonds\(^1\). The insertion reaction normally involves transition-metal-catalyzed cleavage of the bond in question and subsequent insertion of unsaturated units, such as alkenes\(^1\), alkynes\(^1\), 1,3-dienes\(^1\), or carbonoids\(^1\). These elegant reactions have emerged as an attractive approach to rapid building of complex structures from readily available starting materials. In this context, insertion of atoms into aromatic carbon–nitrogen bonds is an appealing method for the synthesis of nitrogen-containing molecules and has the advantage of the availability and the abundance of anilines. However, the direct cleavage of aromatic carbon–nitrogen bonds is challenging due to the particularly inert and stable nature of these bonds\(^1\). Although aromatic carbon–nitrogen bonds can be activated by converting anilines to more reactive intermediates such as aryldiazonium salts\(^1\), alyl ammonium salts\(^1\), amides\(^1\), or triazenes\(^1\), the nitrogen atom is usually discarded in byproducts (Fig. 1a).

Chiral α-branched benzylic amines are important structural motifs found in a wide range of natural products and biologically active compounds\(^1\). Driven by the value of active pharmaceutical ingredients, the asymmetric arylation of aldehydes by arylmetallic reagents, including lithium\(^1\), zinc\(^1\), titanium\(^1\), tin\(^1\), and boron reagents\(^1\), has been established as an efficient method for the synthesis of enantio-pure benzylic amines. Enantioselective one-carbon insertion into the aromatic carbon–nitrogen bond is an appealing route to establish nitrogen-substituted benzylic stereocenters, and this reaction could satisfy an unmet need in reaction design (Fig. 1c).

Here, we report a formal, enantioselective aromatic carbon–nitrogen bond one-carbon insertion reaction that converts an aniline to a highly functionalized chiral α-branched benzylic amine via an aromaticity disassembly-reconstruction process. The process involves oxidative dearomatization of para-substituted anilines, chiral sulfur ylide-mediated asymmetric aziridination, and subsequent rearrangement. Chiral sulfur ylides serve as the one-carbon insertion unit.

**Results**

**Initial tests.** In connection with our recent works on the dearomatization conversion of anilines, oxidative dearomatization can transform the aromatic carbon–nitrogen bond in anilines to a carbon–nitrogen double bond by destroying the aromatic system\(^1\). As shown in Fig. 2, chiral sulfur ylides might serve as a one-carbon unit to be introduced through asymmetric aziridination\(^1\). Subsequent rearrangement might be promoted by a Brønsted or Lewis acid to redevelop the aromaticity and complete the formal enantioselective one-carbon insertion. This builds the nitrogen-substituted benzylic stereocenter and is accompanied by migration of the para-substituent to the meta position and concomitant para-substitution by a nucleophilic reagent. To implement this strategy, the rapid oxidative dearomatization of p-toluidine 1 was tested by examining various oxidants including mCPBA, AcO\(\cdot\)OH, t-BuOO\(\cdot\)H, HD\(\cdot\), Ph\(\cdot\)O(\(\text{OAc}\))\(\cdot\), and PhIO. PhIO together with methanol as the solvent proved to be the best oxidation conditions for the dearomatization. After removing the methanol in vacuo, the crude dearomatized product was mixed with a solution of achiral sulfonium salt S1 in acetonitrile in the presence of 1.2 equivalents of Na\(\cdot\), followed by the treatment with 2 equivalents of CF\(\cdot\)CO\(\cdot\)OH (Fig. 3). To our delight, the aziridination and subsequent rearrangement proceeded smoothly and delivered benzylic amine 2 in good yield (71%).

**Optimization of reaction conditions.** Encouraged by this result, a chiral sulfonium salt S2 derived from the Metzner sulfide\(^1\) was employed, and this reaction gave rise to compound 2 with 51% yield and 17% ee. Various chiral sulfonium salts were examined\(^1\), and S8, derived from isothiocinone\(\cdot\)6\(\cdot\) was observed to be the best chiral ylide precursor, leading to a 64% yield and 95% ee of 2. Changing the anion of sulfonium salts has an influence on the yield of 2 but leads to no change in the enantioselectivity. Reaction with sulfonium trifluoromethanesulfonate S10 provided 2 in 78% yield and 94% ee. Changing the nature of protecting group on the aniline nitrogen atom has a major effect on the transformation. The reaction works well with various sulfamide groups but not with acetamide or benzamide. A set of reaction variables including bases, Lewis and Brønsted acids, solvents, temperatures, and the ratio of reagents were investigated to establish the optimum reaction conditions. Na\(\cdot\) proved to be the best base. A variety of Brønsted or Lewis acids showed different activities to promote the rearrangement. When 20 mol% Cu(OTf)\(\cdot\) was used instead of 2 equivalents CF\(\cdot\)CO\(\cdot\), the yield of 2 was improved to 79% yield and 96% ee (for details, see Supplementary Table 1 in the Supplementary Information).
Scope of anilines. The scope of this transformation was investigated by systematically varying the anilines and the chiral sulfonium salts. As shown in Fig. 4, reactions of a range of anilines with the chiral benzyl sulfonium salt S10 proceeded smoothly. In addition to the methyl group, ethyl, n-butyl, isopropyl, cyclohexyl, or phenyl groups can be the para-substituent in the anilines and migrate to the meta position in the product. An electronic effect was observed for anilines with different meta-substituents. For example, anilines with a meta-phenyl group gave 9 in higher yield than the reaction with a meta-methyl group, and aniline bearing a meta-4-fluorophenyl group gave 12 in higher yield than that bearing a meta-4-methoxyphenyl group. The ortho-substituent of anilines have an effect on the reaction. When 2-fluoro-4-methylaniline was employed, the 4-methyl group migrated to the C-3 position, leading to the formation of 17 in 61% yield and 99% ee. When 2-bromo-4-methylanilines were used, the reaction gave rise to a mixture of the corresponding C-3 or C-5 migration products 18. Reaction of 4-methyl-2-(phenylethynyl)aniline also provided a mixture of the C-3 or C-5 migration products 19. The formation of the mixture of migration products might be caused by the combined influence of the electron-withdrawing and steric effects of the ortho-substituent. The electron-withdrawing effect makes the C-3 position more positively charged compared to the C-5 position, and the steric effect makes the C-3 position more hindered than the C-5 position.

Due to the strong electron-withdrawing property and the small size of the fluorine atom, the C-3 position is the preferred site for the migration of the 4-methyl group. Therefore the reaction of 2-fluoro-4-methylaniline only produced the C-3 migration product 17. When the ortho-substituent is a bromine atom or a phenylethynyl group, the relatively weaker electron-withdrawing property and the bigger size led to the formation of mixture of the C-3 or C-5 migration products. Different functional groups can be introduced into the para-position by varying the solvent used in the dearomatization step. For example, the use of ethanol, isopropanol or trifluoroethanol instead of methanol led to the formation of the 4-ethoxy, the 4-isopropoxy, or the 4-trifluoroethoxy-substituted products 20–22.

Substrate scope of sulfonium salts. A wide range of substituents, such as alkyl, methoxy, halogens, trifluoromethyl, phenyl, ester, or boron functional groups on the aryl group of chiral benzyl sulfonium salts, is tolerated under the reaction conditions (Fig. 5). The reaction proceeds smoothly and independently of the different electronic demands on the aryl substituents of chiral benzyl sulfonium salts. For example, the reaction involving a 4-methylphenyl or 4-(trifluoromethyl)phenyl gave rise to compound 25 in 79% yield with 95% ee and 35 in 76% yield with 92% ee. Changing the
substituent position in benzyl sulfonium salts affected the reaction yield and enantioselectivity. For example, the 2-methoxy substituted benzyl sulfonium salt gave compound $26$ in 91% yield with 96% ee, and the 4-methoxy substituted salt gave compound $28$ in 58% yield with 92% ee. The reaction of a sulfonium salt bearing two meta-tert-butyl groups provided $41$ in 77% yield with 95% ee. When furan-3-ylmethyl sulfonium salts were employed, the reaction provided $α$-furan substituted benzylic amine $43$ in 59 yield with 80% ee. When $α$-unsubstituted allyl and propargyl sulfonium salts were employed, the corresponding $α$-branched benzylic amines $45$ and $46$ were

3 equivalents of CF$_3$COOH was used instead of Cu(OTf)$_2$. b20 mol% of Sc(OTf)$_3$ was used instead of Cu(OTf)$_2$. 

subststituent position in benzyl sulfonium salts affected the reaction yield and enantioselectivity. For example, the 2-methoxy substituted benzyl sulfonium salt gave compound $26$ in 91% yield with 96% ee, and the 4-methoxy substituted salt gave compound $28$ in 58% yield with 92% ee. The reaction of a sulfonium salt bearing two meta-tert-butyl groups provided $41$ in 77% yield with 95% ee. When furan-3-ylmethyl sulfonium salts were employed, the reaction provided $α$-furan substituted benzylic amine $43$ in 59 yield with 80% ee. When $α$-unsubstituted allyl and propargyl sulfonium salts were employed, the corresponding $α$-branched benzylic amines $45$ and $46$ were
formed in moderate yields but with lower enantioselectivity. As the steric hindrance of the allyl sulfonimines salt increases by incorporation of an α-methyl substituent, the stereochemical control of the reaction increases markedly leading to the formation of 46 in 96% ee, but the yield decreased. When the steric hindrance of anilines is increased by incorporation of an ortho-methyl substituent, product 47 was not formed because the corresponding aziridination reaction did not occur. The absolute configuration of 34 was confirmed by X-ray crystallography (see Supplementary Fig. 1 in the Supplementary Information).

Mechanistic studies. To gain more insight into the transformation, the corresponding dearomatized intermediate 48 and the azidination intermediate 49 were isolated. Both of them can be converted into product 2 under the standard conditions (Fig. 6a). When unsubstituted benzenamine was employed as the substrate, 2.1 equivalents of PhIO were required to facilitate the oxidative dearomatization to generate a quinone imine ketal 51 as the intermediate. However, the reaction of 51 under the standard conditions gave rise to N-(4-methoxyphenyl)-4-methylbenzenesulfonamide 52 instead of the insertion product (Fig. 6b). When two aziridination intermediates 53 and 54 were mixed and treated with Cu(OTf)2, the reaction gave rise to compounds 55 and 56, and the formation of 57 and 58 was not observed (Fig. 6c). This result indicated the migration of the para-alkyl group proceeds via an intramolecular manner.

Fig. 5 Scope of chiral sulfonium salts. Ts 4-toluene-sulfonyl.
A plausible pathway for this transformation was depicted in Fig. 7. PhIO mediates the oxidative dearomatization of para-substituted anilines in methanol to generate cyclohexadienimes. The nucleophilic addition of chiral sulfur ylides to cyclohexadienimes and subsequent cyclization lead to the generation of the spiro intermediates. Rearomatizing to release the tension of the spiro structure is a great driving force for the rearrangement. With the aid of a Brønsted or Lewis acid, the migration of the alkyl or the aryl group forms intermediate I (path a), while the migration of the methoxy group forms intermediate II (path b). Because the positive charge in intermediate I can be stabilized by the oxygen atom (intermediate III), rearrangement via path a is preferred. Final aromatization delivers the one-carbon insertion products.

When the substituent at the para-position of amino group was a methoxy group, dearomatization occurred to give an acetal intermediate, but aziridination and C–C bond cleavage were not observed under standard conditions.

**Synthetic applications.** The reaction magnifying 50 times can occur normally which can get product in 77% yield and 94% ee (Fig. 8a). Transformations of the one-carbon insertion products have been explored. For example, under reductive conditions, the N-tosyl protecting group of compound 2 can be removed, leading to the formation of N–H free chiral benzylic amine 48 (Fig. 8b). Compound 23 bearing an ortho-methyl group undergoes a radical sp3 C–H amination reaction to form a 1-substituted isoindoline 49 (Fig. 8c). Compound 33 with an ortho-iodo group is readily converted to the 1,3-disubstituted isoindoline 50 via a Pd-catalyzed cascade coupling/cyclization reaction (Fig. 8d). In these transformations, the enantiopurity of the substrates is preserved in the products.

**Discussion**

In summary, we report a formal enantioselective aromatic carbon–nitrogen bond one-carbon insertion reaction via an aromaticity disassembly-reconstruction process to directly convert...
Stirred at rt for 3 h, then Cu(OTf)2 (0.02 mmol) was added. After the intermediate was completely consumed (monitored by TLC analysis), the reaction was quenched with saturated NaHCO3 (25 mL), and extracted with EtOAc (25 mL × 3). The organic layer was dried over Na2SO4, and concentrated in vacuo. The residue was purified by flash column chromatography on silica gel (eluent: petroleum ether/EtOAc) to furnish the desired compound. White solid; mp: 105–106 °C; 1H NMR (400 MHz, CDCl3): δ 7.54 (d, J = 8.2 Hz, 2H), 7.22–7.17 (m, 3H), 7.15–7.10 (m, 4H), 6.84 (dd, J = 8.4, 1.9 Hz, 1H), 6.80–6.72 (m, J = 2.0 Hz, 1H), 6.62 (d, J = 8.4 Hz, 1H), 5.48 (d, J = 7.1 Hz, 1H), 5.23 (d, J = 7.1 Hz, 1H), 3.75 (s, 3H), 2.37 (s, 3H), 2.05 (s, 3H); 13C NMR (101 MHz, CDCl3): δ 157.1, 143.0, 140.8, 137.4, 132.1, 129.7, 129.2, 128.4, 127.3, 127.2, 126.7, 125.8, 109.6, 60.9, 55.3, 21.4, 16.1; HRMS (m/z): [M + Na]+ calcd. for C22H23NO3S, 404.1291; found, 404.1291. The ee value was determined by HPLC analysis. Chiralcel OD-H Column, hexane/2-propanol = 90/10, 25 °C, 1.0 mL/min, 220 nm, retention time: 15.8 min (minor) and 21.3 min (major).

Anilines to chiral α-branched benzylic amines. The process involves three steps: oxidative dearomatization to activate the aromatic carbon–nitrogen bond in para-substituted anilines by breaking the aromatic system, chiral sulfur ylide-mediated asymmetric aziridination to introduce the one-carbon unit, and subsequent rearrangement to recover the aromaticity and complete the formal enantioselective one-carbon insertion accompanied by a migration of the para-substituent to the meta position and concomitant para-substitution by a nucleophilic reagent. Development of extensions of this group insertion strategy to other aromatic systems is currently in progress in this laboratory.

**Methods**

**Representative procedure.** PhIO (0.22 mmol) was added to a solution of N-Ts p-toluidine 1 (0.2 mmol) in MeOH (2.0 mL) at 25 °C. After 5 min, the reaction mixture was concentrated in vacuo. The residue was mixed with the sulfonium salt and sodium hydride (0.24 mmol) in MeCN (2 mL). The reaction was stirred at rt for 3 h, then Cu(OTf)2 (0.02 mmol) was added. After the intermediate was completely consumed (monitored by TLC analysis), the reaction was quenched with saturated NaHCO3, and extracted with EtOAc (25 mL × 3). The organic layer was dried over Na2SO4, and concentrated in vacuo. The residue was purified by flash column chromatography on silica gel (eluent: petroleum ether/EtOAc) to furnish the desired compound. White solid; mp: 105–106 °C; 1H NMR (400 MHz, CDCl3): δ 7.54 (d, J = 8.2 Hz, 2H), 7.22–7.17 (m, 3H), 7.15–7.10 (m, 4H), 6.84 (dd, J = 8.4, 1.9 Hz, 1H), 6.80–6.72 (m, J = 2.0 Hz, 1H), 6.62 (d, J = 8.4 Hz, 1H), 5.48 (d, J = 7.1 Hz, 1H), 5.23 (d, J = 7.1 Hz, 1H), 3.75 (s, 3H), 2.37 (s, 3H), 2.05 (s, 3H); 13C NMR (101 MHz, CDCl3): δ 157.1, 143.0, 140.8, 137.4, 132.1, 129.7, 129.2, 128.4, 127.3, 127.2, 126.7, 125.8, 109.6, 60.9, 55.3, 21.4, 16.1; HRMS (m/z): [M + Na]+ calcd. for C22H23NO3S, 404.1291; found, 404.1291.
