Abstract

Synergistic extraction of trivalent lanthanoid (Ln(III)) ions with 4-isopropyltropolone (Hipt) and 1,10-phenanthroline (phen) in o-dichrolobenzene (DCB) was investigated. The synergistic effect in DCB is more significant than that in toluene, and the polynuclear complexes found in toluene are not formed in DCB. Based on the 3-dimensional equilibrium analysis, the extracted species for La(III), Eu(III), and Lu(III) are found to be ion-pairs such as Ln(ipt)₂phen·ClO₄⁻ and Ln(ipt)₂(phen)₂·ClO₄⁻ in the presence of NaClO₄ as a salt and the extraction constants of the respective species were determined. The simultaneous extraction of different lanthanoids in the present extraction system was demonstrated. The separation factors between lighter lanthanoids were larger than those with 2-ethylhexyl phosphonic acid mono-2-ethylhexyl ester, an excellent extractant for separation of lanthanoid ions, in decane.

Keywords: lanthanoid, 4-isopropyltropolone, 1,10-phenanthroline, synergistic extraction
**Introduction**

Synergistic extraction of trivalent lanthanoid (Ln(III)) ions has been investigated extensively with the co-use of acidic chelating extractants such as β-diketones,\textsuperscript{1-10} 8-quinolinol derivatives,\textsuperscript{11-13} and tropolone derivatives\textsuperscript{14,15} and neutral ligands such as tributylphosphate,\textsuperscript{1,2} trioctylphosphine oxide,\textsuperscript{1,10,15} crown ethers,\textsuperscript{7,8} and 1, 10-phenanthroline (phen) derivatives.\textsuperscript{3,6,14} The synergistic effect is explained by the adduct complex formation of metal chelates with neutral ligands in the extraction phase, allowing for displacement of coordinated water molecules in Ln(III) species extracted with the chelating agent alone. Thus, the synergistic enhancement of the extractability of Ln(III) was widely reported for various combinations of above-mentioned chelating agents and neutral ligands. On the other hand, since the extraction enhancement occurs across Ln(III) series, there are reported to be limited synergistic extraction systems that improve separation efficiency between different lanthanoids,\textsuperscript{3,6} such as the one with 2-thienoyltrifluoroacetone and phen.

We demonstrated superior synergistic effect on heavier Ln(III) with the co-use of 4-isopropyltropolone (Hipt) and phen in toluene,\textsuperscript{14} making this extraction system a promising candidate for superior separation of lanthanoids. Hipt alone extracts Ln(III) in the form as the polynuclear metal complexes,\textsuperscript{16,17} which are disadvantageous to extraction separation of different lanthanoids because these lanthanoids are co-extracted via formation of heteropolynuclear complexes containing them. On the other hand, the presence of phen as a synergist inhibits the formation of such polynuclear complexes substantially but not completely by adduct complex formation.\textsuperscript{14}

In the present study, the synergistic extraction of Ln(III) with Hipt and phen was investigated in o-dichlorobenzene (DCB) that has higher dielectric constant than toluene and thus is promising as an extraction diluent to inhibit formation of polynuclear complexes.\textsuperscript{17} As a result
of equilibrium analysis of the extraction data, it is found that the Ln(III) species are extracted not as polynuclear complexes but as ion pair in the presence of ClO$_4^-$ into DCB phase. The separation factors between different lanthanoids in the present extraction system was also examined by the simultaneous extraction of all the Ln(III) ions except Pm(III).

**Experimental**

**Reagents and chemicals**

Hipt (TCI, guaranteed reagent grade) was used without further purification. Phen (Ishizu, guaranteed reagent grade) was used as an anhydrate after recrystallization using benzene. All other chemicals were analytical or guaranteed reagent grade, and used without further purification. Deionized water (18.2 MΩ) provided with a Milli-Q equipment (Millipore, Gradient A10) was used throughout.

**Apparatus**

A reciprocal shaker (TAITEC, SR-2) was used for the agitation of the aqueous and organic phases. A pH meter (HORIBA, F-52) equipped with a micro glass combined electrode (HORIBA, 9678-10D) was calibrated with standard pH buffer solutions. An inductively coupled plasma mass spectrometer (ICP-MS, Seiko Instruments SPQ 8000) or a polarized Zeeman graphite furnace atomic absorption spectrophotometer (GFAAS, Hitachi, Z-8270) was used for the determination of Ln(III) in aqueous solutions. A UV/Vis spectrophotometer (JASCO, V-570) was used for the determination of Hipt and phen in the aqueous and organic phases. An electrospray ionization time-of-flight mass spectrometer (MICROMASS, micromass LCT or JEOL, JMS-T100 TD) was used for identification of the Ln(III) species extracted to the organic phase.
**Extraction procedure**

An aliquot (5.0 cm$^3$) of an aqueous phase containing $1.0 \times 10^{-6} - 1.0 \times 10^{-4}$ mol dm$^{-3}$ (typically $1.0 \times 10^{-5}$ mol dm$^{-3}$) Ln(III), $1.0 \times 10^{-1}$ mol dm$^{-3}$ NaCl or NaClO$_4$, and $1.0 \times 10^{-3}$ mol dm$^{-3}$ pH buffers (monochloroacetic acid, acetic acid, MES) and an aliquot (5.0 cm$^3$) of an organic phase containing $2.5 \times 10^{-5} - 5.0 \times 10^{-3}$ mol dm$^{-3}$ Hipt and $1.0 \times 10^{-5} - 1.0 \times 10^{-2}$ mol dm$^{-3}$ phen were shaken mechanically for 1 h at 25 °C. After two phases were separated by centrifugation, the pH value in the aqueous phase was measured. The metal concentration in the aqueous and the organic phase (after back-extraction into an equal volume of 0.1 mol dm$^{-3}$ nitric acid solution by shaking for 1 h) was determined by GFAAS or ICP-MS. The distribution ratio ($D$) was calculated from the concentrations of Ln(III) in both phases. In the case of simultaneous extraction of all Ln(III) ions except Pm(III), the concentrations of Ln(III) ions were reduced to $1.0 \times 10^{-6}$ mol dm$^{-3}$ so that an excess amount of Hipt and phen over Ln(III) were contained in the solution.

To determine the distribution constant of Hipt, an aliquot (5.0 cm$^3$) of the organic (DCB) phase containing $1.0 \times 10^{-2}$ mol dm$^{-3}$ Hipt and an aliquot (5.0 cm$^3$) of the aqueous phase containing $1.0 \times 10^{-1}$ mol dm$^{-3}$ NaClO$_4$ and pH buffers ($1.0 \times 10^{-3}$ mol dm$^{-3}$ acetic acid, $1.0 \times 10^{-3}$ mol dm$^{-3}$ MES, $7.1 \times 10^{-3}$ mol dm$^{-3}$ MOPS, or $5.6 \times 10^{-3}$ mol dm$^{-3}$ TAPS) were shaken mechanically for 1 h at 25 °C. The pH value of the aqueous phase was adjusted to 2–9 with $1.0 \times 10^{-1}$ mol dm$^{-3}$ HCl and $1.0 \times 10^{-1}$ mol dm$^{-3}$ NaOH. After the two phases were separated by centrifugation, the pH value of the aqueous phase was measured. An aliquot of the aqueous phase was diluted to be a solution containing $1.0 \times 10^{-1}$ mol dm$^{-3}$ NaOH and $1.0 \times 10^{-1}$ mol dm$^{-3}$ NaCl in which Hipt was completely dissociated. Then the absorbance of ipt$^-$ in the solution was measured at 387 nm. The concentration of total Hipt in the aqueous phase was determined from the absorbance measured and the molar absorptivity of ipt$^-$ determined separately as $1.16 \times 10^4$ dm$^3$ mol$^{-1}$ cm$^{-1}$. Hipt in the organic phase was back-extracted with 0.1 mol dm$^{-3}$ NaOH, and the concentration was determined in the same manner as that in the aqueous phase. The distribution ratio of Hipt was
calculated according to the following equation.

\[
D_{\text{Hipt}} = \frac{c_{\text{Hipt, org}}}{c_{\text{Hipt, aq}}},
\]

(1)

where \( c_{\text{Hipt, org}} \) and \( c_{\text{Hipt, aq}} \) are the total concentrations of Hipt in the organic and aqueous phases, respectively.

To determine the distribution constant of phen, an aliquot (5.0 cm\(^3\)) of the DCB phase containing \( 1.0 \times 10^{-3} \) mol dm\(^{-3}\) phen and an aliquot (5.0 cm\(^3\)) of the aqueous phase containing \( 1.0 \times 10^{-1} \) mol dm\(^{-3}\) NaCl or NaClO\(_4\) and \( 1.0 \times 10^{-3} \) mol dm\(^{-3}\) pH buffers (monochloroacetic acid, acetic acid, MES, or MOPS) were shaken mechanically for 1 h at 25 °C. The pH value of the aqueous phase was adjusted to 1–8 with \( 1.0 \times 10^{-1} \) mol dm\(^{-3}\) HCl and \( 1.0 \times 10^{-1} \) mol dm\(^{-3}\) NaOH. After centrifugation, the pH value of the aqueous phase was measured. An aliquot of the aqueous phase was diluted to be a solution containing \( 1.0 \times 10^{-1} \) mol dm\(^{-3}\) sulfuric acid to form Hphen\(^+\) completely. Then the absorbance of Hphen\(^+\) in the solution was measured at 271 nm. The concentration of total phen in the aqueous phase was determined from the absorbance measured and the molar absorptivity of Hphen\(^+\) determined separately as \( 3.02 \times 10^4 \) dm\(^3\) mol\(^{-1}\) cm\(^{-1}\). Phen in the organic phase was back-extracted with 0.1 mol dm\(^{-3}\) sulfuric acid, and the concentration was determined in the same manner as that in the aqueous phase. The distribution ratio of phen was calculated according to the following equation.

\[
D_{\text{phen}} = \frac{c_{\text{phen, org}}}{c_{\text{phen, aq}}},
\]

(2)

where \( c_{\text{phen, org}} \) and \( c_{\text{phen, aq}} \) are the total concentrations of phen in the organic and aqueous phases, respectively.

**Results and Discussion**
The extraction behavior of Ln(III) with Hipt and phen

Figure 1 shows the logarithmic distribution ratio (logD) of Ln(III) with Hipt in the presence or absence of phen in DCB and toluene as a function of pH in the aqueous phase. The logD was found to be enhanced in the presence of phen, and the enhancement is more significant in DCB. As shown in Fig. S1 (Supporting Information), the logD of Ln(III) in DCB is independent of metal concentration, indicating that Ln(III) is extracted as a mononuclear metal complex. Furthermore, the synergistic extraction behavior in DCB is found to depend on the type of salts used, i.e. the extractability with NaClO₄ is higher than that with NaCl (Fig. 2), suggesting that ClO₄⁻ is involved with the extraction of Ln(III), e.g. Ln(III) species is extracted into DCB as an ion pair with ClO₄⁻. In the following, we analyzed the extraction behavior of Ln(III) in the synergistic extraction system with Hipt, phen, and ClO₄⁻ in DCB (Hipt-phen-ClO₄⁻-DCB system) based on the extraction equilibrium. For that purpose, we also elucidated the distribution behavior of Hipt and phen in DCB in the presence of ClO₄⁻.

Determination of distribution constant of Hipt in DCB

Figure 3 shows the distribution ratio \(D_{\text{Hipt}}\) of Hipt between the aqueous and DCB phases as a function of pH. The distribution curve shows a typical distribution profile for a monobasic acid, i.e. at lower pH region where the neutral Hipt is dominant, log\(D_{\text{Hipt}}\) is almost constant, while log\(D_{\text{Hipt}}\) follows a straight line having the slope of \(-1\) at higher pH region where anionic ipt⁻ is dominant. The experimentally determined \(D_{\text{Hipt}}\) value is expressed as follows.

\[
D_{\text{Hipt}} = \frac{K_{D,\text{Hipt}}}{1 + (K_{a,\text{Hipt}}/[H^+])},
\]

where the distribution constant \(K_{D,\text{Hipt}}\) and the acid dissociation constant \(K_{a,\text{Hipt}}\) of Hipt are defined by

\[
K_{D,\text{Hipt}} = \frac{K_{D,\text{Hipt}}}{1 + (K_{a,\text{Hipt}}/[H^+])},
\]

\[
K_{a,\text{Hipt}} = \frac{K_{a,\text{Hipt}}}{1 + (K_{a,\text{Hipt}}/[H^+])}.
\]
By fitting log$D_{Hipt}$ curve in Fig. 3 by a nonlinear least-squares method based on Eq. (3), the values of log$K_{D,Hipt}$ and p$K_{a,Hipt}$ were determined as 2.59 ± 0.01 and 7.04 ± 0.02, respectively. The calculated results (a solid curve in Fig. 3) reproduced the experimental data well, and the value of p$K_{a,Hipt}$ is consistent with the reported one (7.06). 18

**Determination of distribution constant of phen in DCB**

Figure 4 shows the distribution ratio ($D_{phen}$) of phen between the aqueous and DCB phases as a function of pH. In the presence of Cl$^-$, the distribution curve shows a typical distribution profile for a monoacidic base where log$D_{phen}$ is almost constant at higher pH region and follows a straight line having the slope of 1 at lower pH region. On the other hand, in the presence of ClO$_4^-$, log$D_{phen}$ at lower pH region (pH <3) is larger than that in the presence of Cl$^-$ and seems to approach the constant value. The distribution behavior can be explained by the ion-pair extraction of protonated Hphen$^+$ with ClO$_4^-$, and $D_{phen}$ in the presence of Cl$^-$ and ClO$_4^-$ is expressed as follows.

$$D_{phen, Cl^-} = \frac{K_{D,phen}}{1 + ([H^+] / K_{a,Hphen^+})}$$  \hspace{1cm} (6)

$$D_{phen, ClO_4^-} = \frac{K_{I,phen}[ClO_4^-][H^+] + K_{D,phen}K_{a,Hphen^+}}{K_{a,Hphen^+} + [H^+]}$$  \hspace{1cm} (7)

where $K_{D,phen}$, $K_{a,Hphen^+}$, and $K_{I,phen}$ are the distribution constant of phen, the acid dissociation constant of Hphen$^+$, and ion-pair extraction constant of Hphen$^+$ with ClO$_4^-$, respectively, and they are given by
The two log $D_{\text{phen}}$ curves in Fig. 4 were fitted by a nonlinear least-squares method based on Eq. (6) or (7). The values of $\log K_{D,\text{phen}}$, $pK_{a,\text{Hphen}^+}$, and $\log K_{I,\text{phen}}$ determined are shown in Table 1. The calculated results (solid curves in Fig. 4) reproduced the experimental data well, and the value of $pK_{a,\text{Hphen}^+}$ is consistent with the reported one (4.94). 19

**Extraction equilibrium analysis of Ln(III) extraction with Hipt and phen**

The distribution ratio of Ln(III) in the Hipt-phen-ClO$_4^-$-DCB system was determined at various pH and concentrations of Hipt and phen. In Fig. 5(a), the logarithmic distribution ratio ($\log D$) for La(III) at a fixed concentration of phen in DCB phase ([phen]$_{\text{org}}$) was plotted as a function of the logarithmic concentration of ipt$^-$ in the aqueous phase, [ipt$^-$], that was given by

$$[\text{ipt}^-] = \frac{c_{\text{Hipt}}}{(K_{D,\text{Hipt}} + 1)[\text{H}^+] / K_{a,\text{Hipt}} + 1}.$$  

(11)

Where $c_{\text{Hipt}}$ is the initial concentration of Hipt. From the slope of the log $D$-log[ipt$^-$] plot, La(III) is found to be coordinated by the two ipt$^-$ molecules, suggesting that La(III) forms a monocationic complex and is extracted as an ion-pair with ClO$_4^-$ into DCB. In Fig. 5(b), log $D$ at a fixed [ipt$^-$] was plotted as a function of [phen]$_{\text{org}}$, that is expressed as follows.

$$[\text{phen}]_{\text{org}} = \frac{c_{\text{phen}}}{\left(1 + \frac{1}{K_{D,\text{phen}}} \left(1 + \frac{[\text{H}^+]}{K_{a,\text{Hphen}^+}} (1 + K_{I,\text{phen}} [\text{ClO}_4^-])\right)\right)},$$  

(12)
where $c_{\text{phen}}$ is the initial concentration of phen. The slope of the plot varies from one to two according to $[\text{phen}]_{\text{org}}$, indicating that the La(III) is extracted as the species coordinated by one phen molecule or as the one coordinated by two phen molecules competitively. The slopes of $\log D-\text{[ipt]}$ plots and $\log D-\text{[phen]}_{\text{org}}$ plots for Eu(III) and Lu(III) are shown in Fig. S2 (Supporting Information). From the slopes of these plots, two ipt$^-$ molecules and one or two phen molecules are found to be coordinated to Eu(III) and Lu(III), similar to La(III).

To clarify the variation of the extracted species, all the experimental distribution ratio data were analyzed according to the following extraction equilibrium. In this case, the extraction equilibrium and the extraction constants are expressed by

$$
\text{Ln}^{3+} + m \text{Hipt}_{\text{org}} + n \text{phen}_{\text{org}} + (3 - m) \text{ClO}_4^- \rightleftharpoons \text{Ln(ipt)}_m(\text{phen})_n(\text{ClO}_4)^{3-m}_{\text{org}} + m \text{H}^+ \tag{13}
$$

$$
K_{\text{ex,smn}} = \frac{[\text{Ln(ipt)}_m(\text{phen})_n(\text{ClO}_4)^{3-m}_{\text{org}}][\text{H}^+]^n}{[\text{Ln}^{3+}][\text{Hipt}]_m[\text{phen}]_n[\text{ClO}_4]^{3-m}_{\text{org}}} \tag{14}
$$

From Eq. (14), the distribution ratio of Ln(III) between the two phases is expressed as follows.

$$
D = \frac{\sum [\text{Ln(ipt)}_m(\text{phen})_n(\text{ClO}_4)^{3-m}_{\text{org}}]}{[\text{Ln}^{3+}]+[\text{Ln(ipt)}^{2+}]} = \frac{1}{(1 + \beta_1(\text{ipt}))} \left( \sum_m \sum_n [\text{ipt}]^m[\text{phen}]^n[\text{ClO}_4]^{3-m} K_{\text{D,Hipt}}^m K_{\text{ex,smn}}^m \right), \tag{15}
$$

where $\beta_1$ represent the formation constant of a 1:1 chelate (Ln(ipt)$^{2+}$) in the aqueous phase, and the constant for each Ln(III) used in this study is shown in Table 2. The existence of other chelate complexes such as 1:2 and 1:3 complexes is assumed to be negligible under the given conditions, as reported previously. The 3-dimensional data of $\log D-\text{[ipt]}-\log[\text{phen}]_{\text{org}}$, shown as the 2D color plot in Fig. 5(c), Fig. S2(c), and Fig. S2(f) were fitted with nonlinear least-squares method based on Eq. (15), and the extraction constants for the respective extracted species were determined. The extracted species are found to be Ln(ipt)$_2$phen·ClO$_4^-$ and Ln(ipt)$_4$(phen)$_2$·ClO$_4$,
and their extraction constants obtained are shown in Table 2. The extraction phases were also analyzed by ESI-MS. The mass spectra for Eu(III) and Lu(III) show the peaks assigned as Ln(ipt)₂phen⁺ and Ln(ipt)₂(phen)₂⁺ (shown in Fig. S3 (Supporting Information)). Thus, the above assignment for the extracted species seems to be reasonable although it is possible that the ESI process influences the composition of the extracted species, e.g. the mass spectrum for La(III) shows the prominent peak assigned as Ln(ipt)₂(phen)₃⁺ whereas Ln(III) species coordinated by three phen molecules are not found predominantly in the extraction data. In the presence of NaCl as a salt instead of NaClO₄ (Hipt-phen-Cl⁻-DCB system), the extracted species for Eu(III) and their extraction constants were determined by the same analysis for the data shown in Fig. S4 (the detail is shown in Supporting Information). As a result, a neutral adduct complex, Ln(ipt)₃phen, was found to be extracted, and the value of logKex,s31 was −0.81. Therefore, the ion-pair extraction of Ln(III) is a unique feature to the Hipt-phen-ClO₄⁻-DCB system and contributes to the superior extractability. The extraction constants, Kex,s21 and Kex,s22, increase with an increase in the atomic number of the Ln(III), as reported in other extraction systems.³⁻⁶ This trend can be explained not only by that ipt⁻, a basic ligand, interacts strongly with heavier Ln(III) with smaller ionic radius but also by that phen forms more stable adduct with heavier Ln(III) chelates.

Separation among lanthanoid ions using Hipt-phen-ClO₄⁻-DCB system

All lanthanoids except for Pm(III) were extracted simultaneously using the Hipt-phen-ClO₄⁻-DCB system for the mutual separation of different lanthanoids. The distribution ratio of each Ln(III) was shown in Fig. 6(a). The logD data for the La(III), Eu(III), and Lu(III) in the figure is consistent with those shown in Fig. 2, where La(III), Eu(III), and Lu(III) are extracted independently in the Hipt-phen-ClO₄⁻-DCB system, indicating that co-extraction of Ln(III) is negligible in the present extraction system. The extraction behavior of Ce(III) seems to be extraordinary at lower pH region, e.g. the logD is deviated from the straight line and the value is
larger than those of Pr(III) and Nd(III) with larger atomic number. One plausible reason for this is that cerium is extracted partially as a tetravalent species, as reported previously. Thus, the extraordinary behavior for the cerium extraction was not found in the presence of ascorbic acid (Fig. 6(b)), which is capable of reducing Ce(IV) to Ce(III).

From the experimental distribution ratios, separation factors between adjacent lanthanoids (\( \alpha_{\text{Ln}(\text{III})/\text{Ln}(\text{III})'} \)) were calculated by \( \alpha_{\text{Ln}(\text{III})/\text{Ln}(\text{III})'} = \frac{D_{\text{Ln}(\text{III})}}{D_{\text{Ln}(\text{III})'}} \), and Figure 7 shows the logarithmic values of \( \alpha_{\text{Ln}(\text{III})/\text{Ln}(\text{III})'} \) under the following conditions, \( \alpha_{\text{Ce}(\text{III})/\text{La}(\text{III})} \) to \( \alpha_{\text{Nd}(\text{III})/\text{Pr}(\text{III})} \) at pH 4.64 and \( \alpha_{\text{Sm}(\text{III})/\text{Nd}(\text{III})} \) to \( \alpha_{\text{La}(\text{III})/\text{Yb}(\text{III})} \) at pH 3.49. The value of \( \alpha_{\text{Gd}(\text{III})/\text{Eu}(\text{III})} \) is found to be almost the unity, indicating that the extractability of Gd(III) and Eu(III) are so similar that the two lanthanoids cannot be separated from each other. This behavior is known as “Gadolinium break”, and originates from the reduction of coordination number from Eu(III) to Gd(III) (9 to 8).

The values of \( \alpha_{\text{Ln}(\text{III})/\text{Ln}(\text{III})'} \) for lighter lanthanoids in the present extraction system are higher than those when the lanthanoids are extracted from nitric acid solution with 2-ethylhexyl phosphonic acid mono-2-ethylhexyl ester (PC-88A) in 1-decane (PC-88A-HNO₃-decane system), which is used as an industrial extraction system, indicating that the present system has the potential to achieve superior efficiency of mutual separation between lighter Ln(III).

The dependence of separation efficiency on the extraction conditions such as concentrations of Hipt and phen was examined based on the determined extraction constants. Figure 8 shows the 3D plot of \( \alpha_{\text{Eu}(\text{III})/\text{La}(\text{III})} \) and \( \alpha_{\text{Lu}(\text{III})/\text{Eu}(\text{III})} \) depending on [ipt] and [phen]org, that is calculated from the values of \( K_{\text{ex,s}21} \) and \( K_{\text{ex,s}22} \) as follows.

\[
\alpha_{\text{Ln}(\text{III})/\text{Ln}(\text{III})'} = \frac{D_{\text{Ln}(\text{III})}}{D_{\text{Ln}(\text{III})'}} = \frac{1}{(1 + \beta_{\text{Ln}(\text{III})}[\text{ipt}])} \prod_{n=1,2} \frac{[\text{ipt}]^2[\text{phen}]^n_{\text{org}}[\text{ClO}_4]^n K_{D,\text{Hipt}}^2}{K_{a,\text{Hipt}}^2 K_{\text{ex,s}2n(\text{Ln}(\text{III}))}}
\]

The values of \( \alpha_{\text{Eu}(\text{III})/\text{La}(\text{III})} \) and \( \alpha_{\text{Lu}(\text{III})/\text{Eu}(\text{III})} \) determined experimentally, also shown in Fig. 8,
are reproduced well by the calculation. For both $\alpha_{\text{Eu(III)/La(III)}}$ and $\alpha_{\text{Lu(III)/Eu(III)}}$, the values are independent of $[\text{ipt}^-]$ and increase with increase in $[\text{phen}]_\text{org}$. The variation of $\alpha_{\text{Eu(III)/La(III)}}$ and $\alpha_{\text{Lu(III)/Eu(III)}}$ to $[\text{phen}]_\text{org}$ is ascribed to the difference in the composition of predominant adduct species: $\text{Ln(ipt)}_2(\text{phen})_2\cdot\text{ClO}_4$ is more dominant at high $[\text{phen}]_\text{org}$ whereas $\text{Ln(ipt)}_2\text{phen}\cdot\text{ClO}_4$ is more dominant at low $[\text{phen}]_\text{org}$. The deviation of $K_{\text{ex,s22}}$ is slightly larger than that of $K_{\text{ex,s21}}$. Therefore, phen as a neutral ligand not only enhances the extractability of Ln(III) but also improves separation efficiency between different lanthanoids.

Conclusions

The synergistic extraction of Ln(III) with Hipt and phen in DCB was investigated, and the extracted species and their extraction constants were determined by a 3D equilibrium analysis. In the presence of NaClO$_4$ as a salt, ion-pairs such as $\text{Ln(ipt)}_2\text{phen}\cdot\text{ClO}_4$ and $\text{Ln(ipt)}_2(\text{phen})_2\cdot\text{ClO}_4$ are extracted into DCB phase, in contrast to the extraction with Hipt alone where polynuclear metal complexes are extracted or the extraction with NaCl as a salt where neutral adduct complexes are extracted. As a result of the simultaneous extraction of different lanthanoids in the Hipt-phen-ClO$_4^-$-DCB system, the separation factors for lighter lanthanoids are found to be larger than those in one of the industrial extraction system, indicating that the present extraction system have the potential to achieve superior separation performance for lighter lanthanoids.

Table 1  Equilibrium constants determined by the distribution experiments of phen between the aqueous and DCB phases at 25 °C.

| Salt       | $\text{pK}_a$ | $\log K_{D,\text{phen}}$ | $\log K_{I,\text{phen}}$ |
|------------|---------------|--------------------------|--------------------------|
| NaCl       | 4.95 ± 0.02   | 1.38 ± 0.01              | —                        |
| NaClO$_4$  | 4.94 ± 0.05   | 1.33 ± 0.03              | -0.10 ± 0.03             |

Table 2 Extraction constants of Ln(III) in the Hipt-phen-CIO$_4^−$-DCB system ($K_{ex,s21}$ and $K_{ex,s22}$) and the formation constants of $\text{Ln}(\text{ipt})^{2+}$ in the aqueous phase at 25 °C.

| Ln(III) | $\log K_{ex,s21}$ | $\log K_{ex,s22}$ | $\log \beta_l$ |
|---------|-------------------|-------------------|----------------|
| La(III) | -1.49 ± 0.04      | 1.43 ± 0.05       | 5.94$^{15}$    |
| Eu(III) | 1.92 ± 0.04       | 5.15 ± 0.07       | 7.04$^{15}$    |
| Lu(III) | 3.86 ± 0.04       | 7.86 ± 0.03       | 8.10$^{15}$    |
**Figure Captions**

Fig. 1  Distribution ratio of La(III) (△, ▲), Eu(III) (○, ●) and Lu(III) (◻, ■) with Hipt in the presence (closed symbols) or absence (opened symbols) of phen. DCB and toluene are used as extraction solvents in panels (a) and (b), respectively. Initial concentrations of Ln(III), Hipt, phen, and NaCl (NaClO₄ only in the case of using Hipt alone in DCB) are 1.0×10⁻⁵ mol dm⁻³, 1.0×10⁻³ mol dm⁻³, 1.0×10⁻³ mol dm⁻³, 1.0×10⁻¹ mol dm⁻³, respectively.

Fig. 2  Salt effect of the distribution ratio of La(III) (△, ▲), Eu(III) (○, ●), and Lu(III) (◻, ■) with Hipt and phen in DCB. 1.0×10⁻¹ mol dm⁻³ NaCl (▲, ●, ■) or 1.0×10⁻¹ mol dm⁻³ NaClO₄ (△, ○, □) was used as a salt. Initial concentrations of Ln(III), Hipt, and phen are 1.0×10⁻⁵ mol dm⁻³, 1.0×10⁻³ mol dm⁻³, 1.0×10⁻³ mol dm⁻³, respectively.

Fig. 3  Distribution ratio of Hipt as a function of pH in the aqueous phase. 1.0×10⁻¹ mol dm⁻³ NaClO₄ is used as a salt. Initial concentration of Hipt is 1.0×10⁻² mol dm⁻³. The solid curve shows the calculated values.

Fig. 4  Distribution ratio of phen as a function of pH in the aqueous phase. 1.0×10⁻¹ mol dm⁻³ NaClO₄ (△) or 1.0×10⁻¹ mol dm⁻³ NaCl (○) is used as a salt. Initial concentration of phen is 1.0×10⁻³ mol dm⁻³. The solid and dotted curves show the calculated values when using NaClO₄ and NaCl, respectively.

Fig. 5 Distribution ratio (D) of La(III) as a function of the concentration of ipt⁻ in the aqueous phase ([ipt⁻]) and/or that of phen in the DCB phase ([phen]_org). Panels (a), (b), and (c) represent a logD-log[ipt⁻] plot at log[phen]_org = −3.02, a logD-log[phen]_org plot at log[ipt⁻] = −6.90, and a 2D color plot of logD as a function of log[ipt⁻] and log[phen]_org, respectively. The solid curves in
panels (a) and (b) show the values calculated from Eq. (15) using the constants in Table 2. Initial concentrations of La(III), Hipt, phen, and NaClO₄ are 1.0×10⁻⁵ mol dm⁻³, 2.5×10⁻⁴–4.0×10⁻³ mol dm⁻³, 1.0×10⁻²–1.0×10⁻¹ mol dm⁻³, and 1.0×10⁻¹ mol dm⁻³, respectively. pH 4.76-6.10.

Fig. 6 Plots of logD–pH for simultaneous extraction of (a) all lanthanoids except Pm(III) and (b) lighter lanthanoids (La(III) to Nd(III)) in the Hipt-phen-ClO₄⁻-DCB system. In panel (b), ascorbic acid was added to reduce Ce(IV). Initial concentrations of Ln(III), Hipt, and phen are 1.0×10⁻⁶ mol dm⁻³, 1.0×10⁻³ mol dm⁻³, and 1.0×10⁻³ mol dm⁻³, respectively. △ La, ◇ Ce, ▽ Pr, ◇ Nd, ▶ Sm, ○ Eu, □ Gd, ▲ Tb, ◆ Dy, ◊ Ho, ◼ Er, □ Tm, ⊙ Yb, □ Lu, △ La alone, ○ Eu alone, □ Lu alone, ▲ La, ◆ Ce, ▼ Pr, ▼ Nd.

Fig. 7 Separation factors between adjacent lanthanoids across the Ln(III) series (α_Ln(III)/Ln(III)') in the Hipt-phen-ClO₄⁻-DCB system (○) and those in the PC-88A-HNO₃-decane system reported previously²² (△). Horizontal axis is the average of atomic numbers of the two lanthanoids to be compared. For Z_Ln(III) = 61, a separation factor between Sm(III) and Nd(III) (Z = 61 and 59) was calculated.

Fig. 8 Separation factors (a) between Eu(III) and La(III) and (b) between Lu(III) and Eu(III), calculated from the extraction constants determined. The circles represent the separation factors determined experimentally.
Fig. 1 Distribution ratio of La(III) (△, ▲), Eu(III) (○, ●) and Lu(III) (◻, ▼) with Hipt in the presence (closed symbols) or absence (opened symbols) of phen. DCB and toluene are used as extraction solvents in panels (a) and (b), respectively. Initial concentrations of Ln(III), Hipt, phen, and NaCl (NaClO₄ only in the case of using Hipt alone in DCB) are $1.0 \times 10^{-5}$ mol dm⁻³, $1.0 \times 10^{-3}$ mol dm⁻³, $1.0 \times 10^{-3}$ mol dm⁻³, $1.0 \times 10^{-1}$ mol dm⁻³, respectively.

Fig. 2 Salt effect of the distribution ratio of La(III) (◬, △), Eu(III) (☉, ●), and Lu(III) (⊡, ▼) with Hipt and phen in DCB. $1.0 \times 10^{-1}$ mol dm⁻³ NaCl (⌂, ●) or $1.0 \times 10^{-1}$ mol dm⁻³ NaClO₄ (⌂, ○, □) was used as a salt. Initial concentrations of Ln(III), Hipt, and phen are $1.0 \times 10^{-5}$ mol dm⁻³, $1.0 \times 10^{-3}$ mol dm⁻³, $1.0 \times 10^{-3}$ mol dm⁻³, respectively.
Fig. 3 Distribution ratio of Hipt as a function of pH in the aqueous phase. $1.0 \times 10^{-1}$ mol dm$^{-3}$ NaClO$_4$ is used as a salt. Initial concentration of Hipt is $1.0 \times 10^{-2}$ mol dm$^{-3}$. The solid curve shows the calculated values.

Fig. 4 Distribution ratio of phen as a function of pH in the aqueous phase. $1.0 \times 10^{-1}$ mol dm$^{-3}$ NaClO$_4$ (△) or $1.0 \times 10^{-1}$ mol dm$^{-3}$ NaCl (○) is used as a salt. Initial concentration of phen is $1.0 \times 10^{-3}$ mol dm$^{-3}$. The solid and dotted curves show the calculated values when using NaClO$_4$ and NaCl, respectively.
Fig. 5 Distribution ratio ($D$) of $\text{La(III)}$ as a function of the concentration of $\text{ipt}^-$ in the aqueous phase ($[\text{ipt}^-]$) and/or that of $\text{phen}$ in the DCB phase ($[\text{phen}]_{\text{org}}$). Panels (a), (b), and (c) represent a log$D$-log$[\text{ipt}^-]$ plot at log$[\text{phen}]_{\text{org}} = -3.02$, a log$D$-log$[\text{phen}]_{\text{org}}$ plot at log$[\text{ipt}^-] = -6.90$, and a 2D color plot of log$D$ as a function of log$[\text{ipt}^-]$ and log$[\text{phen}]_{\text{org}}$, respectively. The solid curves in panels (a) and (b) show the values calculated from Eq. (15) using the constants in Table 2. Initial concentrations of $\text{La(III)}$, $\text{Hipt}$, $\text{phen}$, and $\text{NaClO}_4$ are $1.0 \times 10^{-5}$ mol dm$^{-3}$, $2.5 \times 10^{-4}$–$4.0 \times 10^{-3}$ mol dm$^{-3}$, $1.0 \times 10^{-5}$–$1.0 \times 10^{-2}$ mol dm$^{-3}$, and $1.0 \times 10^{-1}$ mol dm$^{-3}$, respectively. pH 4.76-6.10.

Fig. 6 Plots of log$D$–pH for simultaneous extraction of (a) all lanthanoids except Pm(III) and (b) lighter lanthanoids ($\text{La(III)}$ to Nd(III)) in the Hipt-phen-$\text{ClO}_4^-$-DCB system. In panel (b), ascorbic acid was added to reduce Ce(IV). Initial concentrations of Ln(III), Hipt, and phen are $1.0 \times 10^{-6}$ mol dm$^{-3}$, $1.0 \times 10^{-3}$ mol dm$^{-3}$, and $1.0 \times 10^{-3}$ mol dm$^{-3}$, respectively. $\triangle$ La, $\Diamond$ Ce, $\triangledown$ Pr, $\diamond$ Nd, $\triangleright$ Sm, $\odot$ Eu, $\square$ Gd, $\bowtie$ Tb, $\oplus$ Dy, $\bigstar$ Ho, $\bigcirc$ Er, $\check$ Tm, $\bigotimes$ Yb, $\blacklozenge$ Lu, $\triangle$ La alone, $\bigcirc$ Eu alone, $\blacklozenge$ Lu alone, $\blacktriangleleft$ La, $\blacktriangleleft$ Ce, $\blacktriangledown$ Pr, $\blacktriangleright$ Nd.
Fig. 7 Separation factors between adjacent lanthanoids across the Ln(III) series ($\alpha_{\text{Ln(III)}}/\alpha_{\text{Ln(III)'}}$) in the Hipt-phen-ClO$_4^-$-DCB system (○) and those in the PC-88A-HNO$_3$-decane system reported previously$^{22}$ (△). Horizontal axis is the average of atomic numbers of the two lanthanoids to be compared. For $Z_{\text{Ln(III)}} = 61$, a separation factor between Sm(III) and Nd(III) ($Z = 61$ and 59) was calculated.

Fig. 8 Separation factors (a) between Eu(III) and La(III) and (b) between Lu(III) and Eu(III), calculated from the extraction constants determined. The circles represent the separation factors determined experimentally.
