Abstract
Stochastic bilevel optimization generalizes the classic stochastic optimization from the minimization of a single objective to the minimization of an objective function that depends on the solution of another optimization problem. Recently, stochastic bilevel optimization is regaining popularity in emerging machine learning applications such as hyper-parameter optimization and model-agnostic meta learning. To solve this class of stochastic optimization problems, existing methods require either double-loop or two-timescale updates, which are sometimes less efficient. This paper develops a new optimization method for a class of stochastic bilevel problems that we term Single-Timescale Stochastic BiLevel (STABLE) method. STABLE runs in a single loop fashion, and uses a single-timescale update with a fixed batch size. To achieve an $\epsilon$-stationary point of the bilevel problem, STABLE requires $O(\epsilon^{-2})$ samples in total; and to achieve an $\epsilon$-optimal solution in the strongly convex case, STABLE requires $O(\epsilon^{-1})$ samples. To the best of our knowledge, this is the first bilevel optimization algorithm achieving the same order of sample complexity as the stochastic gradient descent method for the single-level stochastic optimization.

1. Introduction
In this paper, we consider solving the stochastic optimization problems of the following form

$$\begin{align*}
\min_{x \in \mathbb{R}^d} & \quad F(x) := \mathbb{E}_\xi \left[ f(x, y^*(x); \xi) \right] \quad \text{(upper)} \quad (1a) \\
\text{s.t.} & \quad y^*(x) \in \arg\min_{y \in \mathbb{R}^{d'}} \mathbb{E}_\phi [g(x, y; \phi)] \quad \text{(lower)} \quad (1b)
\end{align*}$$

where $f$ and $g$ are differentiable functions; and, $\xi$ and $\phi$ are random variables. The problem (1) is often referred to as the stochastic bilevel problem, where the upper-level optimization problem depends on the solution of the lower-level optimization over $y \in \mathbb{R}^{d'}$, denoted as $y^*(x)$, which depends on the value of upper-level variable $x \in \mathbb{R}^d$.

Bilevel optimization has a long history in operations research. It can be viewed as a generalization of the classic two-stage stochastic programming (Shapiro et al., 2009), in which the upper-level objective function depends on the optimal lower-level objective value rather than the lower-level solution. Earlier works have studied applications in portfolio management and game theory (Stackelberg, 1952); see a survey (Dempe and Zemkoho, 2020). Recently, bilevel optimization has gained growing popularity in a number of machine learning applications such as meta-learning (Rajeswaran...
et al., 2019), reinforcement learning (Konda and Borkar, 1999; Hong et al., 2020), hyper-parameter optimization (Franceschi et al., 2018), continual learning (Borsos et al., 2020), and image processing (Kunisch and Pock, 2013). In some of these applications, when the lower-level problem admits a closed-form solution, bilevel optimization also reduces to the recently studied stochastic compositional optimization (Wang et al., 2017a; Ghadimi et al., 2020; Chen et al., 2020).

Unlike single-level stochastic problems, algorithms tailored for solving bilevel stochastic problems are much less explored. This is partially because solving this class of problems via traditional optimization techniques faces a number of challenges. A key difficulty due to the nested structure is that (stochastic) gradient, a basic element in continuous optimization machinery, is prohibitively expensive or even impossible to compute. As we will show later, since computing an unbiased stochastic gradient of $F(x)$ requires solving the lower-level problem once, running stochastic gradient descent (SGD) on the upper-level problem essentially results in a double-loop algorithm which uses an iterative algorithm to solve the lower-level problem thousands or even millions of times.

1.1. Prior art

To put our work in context, we review prior art that we group in the following two categories.

**Bilevel optimization.** Many recent efforts have been made to solve the bilevel optimization problems. One successful approach is to reformulate the bilevel problem as a single-level problem by replacing the lower-level problem by its optimality conditions (Colson et al., 2007; Kunapuli et al., 2008). Recently, gradient-based first-order methods for bilevel optimization have gained popularity, where the idea is to iteratively approximate the (stochastic) gradient of the upper-level problem either in forward or backward manner (Sabach and Shtern, 2017; Franceschi et al., 2018; Shaban et al., 2019; Grazzi et al., 2020). While most of these works assume the unique solution of the lower-level problem, cases where this assumption does not hold have been tackled in the recent work (Liu et al., 2020). All these algorithms have excellent empirical performance, but many of them either provide no theoretical guarantees or only focus on the asymptotic performance analysis.

The non-asymptotic analysis of bilevel optimization algorithms has been recently studied in some pioneering works, e.g., (Ghadimi and Wang, 2018; Hong et al., 2020; Ji et al., 2020), just to name a few. In both (Ghadimi and Wang, 2018; Ji et al., 2020), bilevel stochastic optimization algorithms have been developed that run in a double-loop manner. To achieve an $\epsilon$-stationary point, they only need the sample complexity $O(\epsilon^{-2})$ that is comparable to the complexity of SGD for the single-level case. Recently, a single-loop two-timescale stochastic approximation algorithm has been developed in (Hong et al., 2020) for the bilevel problem (1). Due to the nature of two-timescale update, it incurs the sub-optimal sample complexity $O(\epsilon^{-2.5})$. Therefore, the existing single-loop solvers for bilevel problems are significantly slower than those for problems without bilevel compositions, but otherwise share many structures and properties.

**Stochastic compositional optimization.** When the lower-level problem in (1b) admits a smooth closed-form solution, the bilevel problem (1) reduces to stochastic compositional optimization

$$\min_{x \in \mathbb{R}^d} F(x) := \mathbb{E}_\xi \left[ f(x, \mathbb{E}_{\phi}[g(x; \phi)]; \xi) \right].$$

(2)

Popular approaches tackling this class of problems use two sequences of variables being updated in two different time scales (Wang et al., 2017a,b). However, the complexity of (Wang et al., 2017a) and (Wang et al., 2017b) is worse than $O(\epsilon^{-2})$ of SGD for the non-compositional case. Building upon recent variance-reduction techniques, variance-reduced methods have been developed to solve
A SINGLE-TIMESCALE STOCHASTIC BILEVEL OPTIMIZATION METHOD

| # of samples (nonconvex) | $\mathcal{O}(\epsilon^{-2})$ in $\xi$ | $\mathcal{O}(\epsilon^{-2})$ in $\xi$ | $\mathcal{O}(\epsilon^{-2.5})$ in $\xi$ | $\tilde{\mathcal{O}}(\epsilon^{-2})$ in $\xi$ |
| # of samples (strongly convex) | $\mathcal{O}(\epsilon^{-1})$ in $\xi$ | $\mathcal{O}(\epsilon^{-1})$ in $\xi$ | $\mathcal{O}(\epsilon^{-1.5})$ in $\xi$ | $\mathcal{O}(\epsilon^{-1})$ in $\xi$ |

Table 1: Sample complexity of several state-of-the-art algorithms (BSA in (Ghadimi and Wang, 2018), TTSA in (Hong et al., 2020), stocBiO in (Ji et al., 2020)) to achieve an $\epsilon$-stationary point of $F(x)$ in the nonconvex setting and an $\epsilon$-optimal solution of $F(x)$ in the strongly convex setting; the notation $\tilde{\mathcal{O}}(\cdot)$ hides logarithmic terms of $\epsilon^{-1}$.

a special class of the stochastic compositional problem with the finite-sum structure, e.g., (Lian et al., 2017; Zhang and Xiao, 2019), but they usually operate in a double-loop manner.

While most of existing algorithms rely on either two-timescale or double-loop updates, the single-timescale single-loop approaches have been recently developed in (Ghadimi et al., 2020; Chen et al., 2020), which achieve the sample complexity $\mathcal{O}(\epsilon^{-2})$. These encouraging recent results imply that solving stochastic compositional optimization is nearly as easy as solving stochastic optimization. However, whether the stochastic optimization techniques used therein permeate to solving more challenging bilevel problems remains unknown. This paper is devoted to answering this question.

1.2. Our contributions

To this end, this paper aims to develop a single-loop single-timescale stochastic algorithm, which, for the class of smooth bilevel problems, can match the sample complexity of SGD for single-level stochastic optimization problems.

In the context of existing methods, our contributions can be summarized as follows.

1. We develop a new stochastic gradient estimator tailored for a certain class of stochastic bilevel problems, which is motivated by an ODE analysis for the corresponding continuous-time deterministic problems. Our new stochastic bilevel gradient estimator is flexible to combine with any existing stochastic optimization algorithms for the single-level problems, and solve this class of stochastic bilevel problems as sample-efficient as single-level problems.

2. When we combine this stochastic gradient estimator with SGD for the upper-level update, we term it as the Single-Timescale stochAstic BiLevEl optimization (STABLE) method. In the nonconvex case, to achieve $\epsilon$-stationary point of (1), STABLE only requires $\mathcal{O}(\epsilon^{-2})$ samples in total. In the strongly convex case, to achieve $\epsilon$-optimal solution of (1), STABLE only requires $\mathcal{O}(\epsilon^{-1})$ samples. To the best of our knowledge, STABLE is the first bilevel algorithm achieving the order of sample complexity as SGD for the classic stochastic single-level problems. See the sample complexity of state-of-the-art algorithms in Table 1.

Trade-off and limitations. While our new bilevel optimization algorithm significantly improves the sample complexity of existing algorithms, it pays the price of additional computation per iteration. Specifically, in order to better estimate the stochastic bilevel gradient, a matrix inversion and an
eigenvalue truncation are needed per iteration, which cost $O(d^3)$ computation for a $d \times d$ matrix. In contrast, some of recent works (Ghadimi and Wang, 2018; Hong et al., 2020; Ji et al., 2020) reduce matrix inversion to more efficient computations of matrix-vector products, which cost $O(d^2)$ computation per iteration. Therefore, our algorithm is preferable in the regime where the sampling is more costly than computation or the dimension $d$ is relatively small.

1.3. Applications

Next we describe two popular applications, all of which can be formulated as a bilevel problem (1).

**Hyper-parameter optimization.** Hyper-parameter optimization aims to find the optimal hyperparameter $x \in \mathbb{R}^d$ (e.g., learning rate, regularization coefficient, neural network architecture), which is used in training a model $w \in \mathbb{R}^d$ on the training set, such that the learned model achieves the low risk on the validation set. Let $\ell(w; \xi)$ denote the loss of the model $w$ on datum $\xi$, and $D_{\text{val}}$ and $D_{\text{tra}}$ denote, respectively, the training and validation datasets. Specifically, considering the sought hyper-parameter as the regularization coefficient (Franceschi et al., 2018), we aim to solve

$$\min_{x \in \mathbb{R}^d} F(x) := \mathbb{E}_{\xi \sim D_{\text{val}}} [\ell(w^*(x); \xi)]$$

$$\text{s.t. } w^*(x) \in \arg \min_{w \in \mathbb{R}^d} \mathbb{E}_{\phi \sim D_{\text{tra}}} [\ell(w; \phi)] + \sum_{i=1}^d x_i w_i^2.$$  

**Model-agnostic meta-learning.** The goal of model-agnostic meta-learning (MAML) is to find a common initialization that can adapt to a desired model for new tasks, which inherently consists of two steps: i) training a model over a variety of learning tasks; ii) refining the model for each task. Consider a set of empirically observed tasks collected in $M := \{1, \ldots, M\}$ drawn from a certain task distribution. Each task $m$ has its local data $\xi_m$ from a certain distribution, which defines its loss function as $F_m(x) := \mathbb{E}_{\xi_m} [\ell(x; \xi_m)]$, $m \in M$, where $x \in \mathbb{R}^d$ is the parameter of a prediction model (e.g., weights of a neural network), and $\ell(x; \xi_m)$ is again the loss on datum $\xi_m$. As an example, the MAML problem can be formulated as the bilevel problem (1), that is (Rajeswaran et al., 2019)

$$\min_{x \in \mathbb{R}^d} F(x) := \frac{1}{M} \sum_{m=1}^M F_m(y_m^*(x))$$

$$\text{s.t. } y_m^*(x) \in \arg \min_{y_m \in \mathbb{R}^d} F_m(y_m) + \frac{\lambda}{2} \|y_m - x\|^2, \forall m$$

where $\lambda$ is a constant and $y_m^*(x)$ is, initialized with $x$, obtained after fine tuning on task $m$.

2. A Single-timescale Stochastic Optimization Method for Bilevel Problems

In this section, we will first provide background of bilevel problems, and then present our stochastic bilevel gradient method, followed by an ODE analysis to highlight the intuition of our design.

2.1. Preliminaries

We use $\|\cdot\|$ to denote the $\ell_2$ norm for vectors and Frobenius norm for matrices. We use $\mathcal{F}^k$ to denote the collection of random variables, i.e., $\mathcal{F}^k := \{\phi^0, \ldots, \phi^{k-1}, \xi^0, \ldots, \xi^{k-1}\}$. For convenience, we
define the deterministic version of (1) as

$$\min_{x \in \mathbb{R}^d} F(x) := f(x, y^*(x)) \quad \text{s. t.} \quad y^*(x) \in \arg \min_{y \in \mathbb{R}^d} g(x, y)$$  \hspace{1cm} (5)$$

where the functions are defined as $g(x, y) := \mathbb{E}[\phi[g(x, y; \xi)]]$ and $f(x, y) := \mathbb{E}[\xi[f(x, y; \xi)]]$.

We also define $\nabla^2_{xy}g(x, y)$ as the Hessian matrix of $g$ with respect to $y$ and define $\nabla^2_{xy}g(x, y)$ as

$$\nabla^2_{xy}g(x, y) := \begin{bmatrix} \frac{\partial^2}{\partial x_1 \partial y_1} g(x, y) & \cdots & \frac{\partial^2}{\partial x_1 \partial y_d} g(x, y) \\ \vdots & \ddots & \vdots \\ \frac{\partial^2}{\partial x_d \partial y_1} g(x, y) & \cdots & \frac{\partial^2}{\partial x_d \partial y_d} g(x, y) \end{bmatrix}.$$

We make the following standard assumptions that are commonly used in stochastic bilevel optimization literature (Ghadimi and Wang, 2018; Hong et al., 2020; Ji et al., 2020).

**Assumption 1 (Lipschitz continuity).** For any fixed $x$, $\nabla_x f(x, \cdot)$, $\nabla_y f(x, \cdot)$, $\nabla_y g(x, y)$, $\nabla^2_{xy}g(x, \cdot; \phi)$, $\nabla^2_{yy}g(x, \cdot; \phi)$ are $L_{fx}, L_{fy}, L_y, L_{gxy}, L_{gyy}$-Lipschitz continuous. For any fixed $y$, $\nabla_x f(\cdot; y, \xi)$, $\nabla_y f(\cdot; y, \xi)$, $\nabla^2_{xy}g(\cdot, y, \phi)$, $\nabla^2_{yy}g(\cdot, y, \phi)$ are $L_{fx}, L_{fy}, L_{gxy}, L_{gyy}$-Lipschitz continuous.

**Assumption 2 (strong convexity of lower-level objective).** For any fixed $x$, $g(x, y)$ is $\mu_y$-strongly convex in $y$, that is, $\nabla^2_{yy}g(x, y) \succeq \mu_y I$.

Assumptions 1 and 2 together ensure that the first- and second-order derivations of $f(x, y)$, $g(x, y)$ as well as the solution mapping $y^*(x)$ are well-behaved.

**Assumption 3 (stochastic derivatives).** The stochastic derivatives $\nabla_x f(x, y; \xi)$, $\nabla_y f(x, y; \xi)$, $\nabla_y g(x, y; \phi)$, $\nabla^2_{xy}g(x, y, \phi)$, and $\nabla^2_{yy}g(x, y, \phi)$ are unbiased estimators of $\nabla_x f(x, y)$, $\nabla_y f(x, y)$, $\nabla_y g(x, y)$, $\nabla^2_{xy}g(x, y)$, and $\nabla^2_{yy}g(x, y)$, respectively; and their variances are bounded by $\sigma^2_{fx}, \sigma^2_{fy}, \sigma^2_{gxy}, \sigma^2_{gyx}, \sigma^2_{gyy}$, respectively. Moreover, their moments are bounded by

$$\mathbb{E}[(\nabla_x f(x, y; \xi))^p] \leq C^p_{fx}, \quad \mathbb{E}[(\nabla_y f(x, y; \xi))^p] \leq C^p_{fy}, \quad p = 2, 4 \hspace{1cm} (6a)$$

$$\mathbb{E}_{\phi}[\|\nabla^2_{xy}g(x, y; \phi)\|^2] \leq C^2_{gxy}, \quad \mathbb{E}_{\phi}[\|\nabla^2_{yy}g(x, y; \phi)\|^2] \leq C^2_{gyy}. \hspace{1cm} (6b)$$

Assumption 3 is the counterpart of the unbiasedness and bounded variance assumption in the single-level stochastic optimization. In addition, the bounded moments in Assumption 3 ensure the Lipschitz continuity of the upper-level gradient $\nabla F(x)$.

We first highlight the inherent challenge of directly applying the single-level SGD method (Robbins and Monro, 1951) to the bilevel problem (1). To illustrate this point, we derive the gradient of the upper-level function $F(x)$ in the next proposition; see the proof in Appendix.

**Proposition 1** Under Assumption 2, we have the gradients

$$\nabla_x y^*(x)^\top := -\nabla^2_{xy}g(x, y^*(x))\left[\nabla^2_{yy}g(x, y^*(x))\right]^{-1} \hspace{1cm} (7a)$$

$$\nabla F(x) = \nabla_x f(x, y^*(x)) + \nabla_x y^*(x)^\top \nabla_y f(x, y^*(x)). \hspace{1cm} (7b)$$

Notice that obtaining an unbiased stochastic estimate of $\nabla F(x)$ and applying SGD on $x$ face two main difficulties: (D1) the gradient $\nabla F(x)$ at $x$ depends on the minimizer of the lower-level problem $y^*(x)$; (D2) even if $y^*(x)$ is known, it is hard to apply the stochastic approximation to obtain an unbiased estimate of $\nabla F(x)$ since $\nabla F(x)$ is nonlinear in $\nabla^2_{yy}g(x, y^*(x))$; see the discussion of (D2) in stochastic compositional optimization literature, e.g., (Wang et al., 2017a; Chen et al., 2020).
Algorithm 1 STABLE for stochastic bilevel problems

1: initialize: $x^0, y^0, H_{xy}^0, H_{yy}^0$, stepsizes $\{\alpha_k, \beta_k\}$.
2: for $k = 0, 1, \ldots, K - 1$ do
3: compute $h_{xy}^{k-1}(\phi^k)$ and $h_{xy}^k(\phi^k)$ \hspace{1cm} \triangleright$randomly select datum $\phi^k$
4: update $H_{xy}^k$ via (12a)
5: compute $h_{yy}^{k-1}(\phi^k)$ and $h_{yy}^k(\phi^k)$
6: update $H_{yy}^k$ via (12b)
7: compute $\nabla_x f(x^k, y^k; \xi^k), \nabla_y f(x^k, y^k; \xi^k)$ \hspace{1cm} \triangleright$randomly select datum $\xi^k$
8: update $x^k$ and $y^k$ via (11)
9: end for

Similar to some existing algorithms for bilevel problems, our method addresses (D1) by evaluating $\nabla F(x)$ on a certain vector $y$ in place of $y^*(x)$, but it differs in how to recursively update $y$ and how to address (D2). Resembling the definition (7) with $y^*(x)$ replaced by $y$, we introduce the notation

$$\nabla_x f(x, y) := \nabla_x f(x, y) - \nabla_x^2 g(x, y) \left[ \nabla_{yy}^2 g(x, y) \right]^{-1} \nabla_y f(x, y). \tag{8}$$

As we will show in Lemma 7 of Appendix, Assumptions 1-3 ensure that $\nabla F(\cdot), \nabla_x f(x, \cdot)$, and $y^*(\cdot)$ are all Lipschitz continuous with constants $L_F, L_f, L_y$, respectively.

2.2. A single-timescale bilevel optimization method

Before we present our method, we first review a successful recent effort. To overcome the difficulty of applying plain-vanilla SGD, a two-timescale stochastic approximation (TTS) algorithm has been recently developed in (Hong et al., 2020). TTSA is a single-loop algorithm and amenable to efficient implementation. It consists of two sequences $\{x^k\}$ and $\{y^k\}$: for a given $x^k$, $y^k$ estimates the minimizer $y^*(x^k)$; and, $x^k$ estimates the minimizer $x^*$. For notational brevity, we define

$$h_g^k := \nabla_y g(x^k, y^k; \phi^k), \quad h_{yy}^k(\phi) := \nabla_{yy}^2 g(x^k, y^k; \phi), \quad h_{xy}^k(\phi) := \nabla_{xy}^2 g(x^k, y^k; \phi). \tag{9}$$

With $\alpha_k$ and $\beta_k$ denoting two sequences of stepsizes, the TTSA recursion is given by

$$\begin{align*}
y^{k+1} &= y^k - \beta_k h_g^k \tag{10a} \\
x^{k+1} &= x^k - \alpha_k \left( \nabla_x f(x^k, y^k; \xi^k) - h_{xy}^k(\phi^k)\nabla_{yy}^{-1} \nabla_y f(x^k, y^k; \xi^k) \right) \tag{10b}
\end{align*}$$

where $\nabla_{yy}^{-1}$ is a mini-batch approximation of $\left[ \nabla_{yy}^2 g(x^k, y^k) \right]^{-1}$. To ensure convergence, TTSA requires $y^k$ to be updated in a timescale faster than that of $x^k$ so that $x^k$ is relatively static with respect to $y^k$; i.e., $\lim_{k \to \infty} \alpha_k / \beta_k = 0$ (Hong et al., 2020). However, this prevents TTSA from choosing the stepsize $O(1/\sqrt{K})$ as SGD, and also results in its suboptimal complexity.

We find that the key reason preventing TTSA from using a single-timescale update is its undesired stochastic upper-level gradient estimator (10b) that uses an inaccurate lower-level variable $y^k$ to approximate $y^*(x^k)$. With more insights given in Section 2.3, we propose a new stochastic bilevel optimization method based on a new stochastic bilevel gradient estimator, which we term Single-Timescale Stochastic Bilevel Optimization (STABLE) method. Its recursion is given by

$$\begin{align*}
x^{k+1} &= x^k - \alpha_k \left( \nabla_x f(x^k, y^k; \xi^k) - H_{xy}^k(H_{yy}^k)^{-1} \nabla_y f(x^k, y^k; \xi^k) \right) \tag{11a} \\
y^{k+1} &= y^k - \beta_k h_g^k - (H_{yy}^k)^{-1}(H_{xy}^k)^{\top}(x^{k+1} - x^k). \tag{11b}
\end{align*}$$
In (11), the estimates of second-order derivatives are updated as (with stepsize $\tau_k > 0$)

$$H_{xy}^k = \mathcal{P} \left( (1 - \tau_k) \left( H_{xy}^{k-1} - h_{xy}^{k-1}(\phi^k) \right) + h_{xy}^k(\phi^k) \right)$$ \hspace{1cm} (12a)

$$H_{yy}^k = \mathcal{P} \left( (1 - \tau_k) \left( H_{yy}^{k-1} - h_{yy}^{k-1}(\phi^k) \right) + h_{yy}^k(\phi^k) \right)$$ \hspace{1cm} (12b)

where $\mathcal{P}$ is the projection to set $\{X : \|X\| \leq C_{g+I}\}$ and $\mathcal{P}$ is the projection to set $\{X : X \succeq \mu_y I\}$.

Compared with (10) and other existing algorithms, the unique features of STABLE lie in: (F1) its $y^k$-update that will be shown to better “predict” the next $y^*(x^{k+1})$; and, (F2) a recursive update of $H_{xy}^k, H_{yy}^k$ that is motivated by the advanced variance reduction techniques for single-level problems (Nguyen et al., 2017; Cutkosky and Orabona, 2019) and the recent stochastic compositional optimization method (Chen et al., 2020). The marriage of (F1)-(F2) enables STABLE to have a better estimate of $\nabla F(x^k)$, which is responsible for its improved convergence. Note that we use three stepsizes $\alpha_k, \beta_k$ and $\tau_k$ in (11), but all of them decrease at the same rate as SGD. As we will show later, for a class of bilevel problems, the single-timescale recursion (11) achieves the same convergence rate as SGD for single-level problems. See a summary of STABLE in Algorithm 1.

**Remark 2** Note that the projection in (12a) is not uncommon in stochastic algorithms to ensure stability, and the eigenvalue truncation in (12b) is a usual subroutine in Newton-based methods, which is also referred to the positive definite truncation (Nocedal and Wright, 2006).

### 2.3. Continuous-time ODE analysis

Similar to the stochastic compositional optimization (Chen et al., 2020), we provide some intuition of our algorithm design via an ODE for the deterministic problem (5). To minimize $F(x)$, we use an ODE analysis to design a continuous dynamic

$$\dot{x}(t) = -\alpha \mathcal{T}(x(t), y(x(t)))$$ \hspace{1cm} (13)

by choosing an operator $\mathcal{T}$. For single-level minimization of a smooth function $h(x(t))$, one can use the gradient flow $\dot{x}(t) = -\alpha \nabla h(x(t))$. For bilevel minimization (5), however, we shall avoid $\mathcal{T}(x, y) = \nabla_x (f(x, y^*(x)))$ and instead use $y$ to approximate $y^*(x)$. Here note that we have dropped (t) for conciseness. Hence, define the operator as

$$\mathcal{T}(x, y) := \nabla_x f(x, y) - \nabla^2_{xy} g(x, y) \left[ \nabla^2_{yy} g(x, y) \right]^{-1} \nabla_y f(x, y) \hspace{1cm} (8) \hspace{1cm} \nabla_x f(x, y).$$ \hspace{1cm} (14)

Here, the variable $y$ follows another dynamic that we specify below, which accompanies the $x$-dynamic (13). We will also find a corresponding Lyapunov function $V$ such that

$$(C1) \dot{V} < 0; \quad \text{and,} \quad (C2) \dot{V} = 0 \text{ if and only if } \nabla F(x) = 0 \text{ and } y = y^*(x).$$

If the $\dot{x}$ and $\dot{y}$ dynamics drive an appropriate Lyapunov function $V$ satisfying (C1) and (C2), then $x$ converges to a stationary point of the upper-level problem $F(x)$ and $y$ converges to the solution of the lower-level problem.

We first state the results for the continuous-time dynamics below.

**Theorem 1 (Continuous-time dynamics)** If we define the $x$- and $y$-dynamics as

$$\dot{x} = -\alpha \nabla_x f(x, y) - \alpha \nabla^2_{xy} g(x, y) \left[ \nabla^2_{yy} g(x, y) \right]^{-1} \nabla_y f(x, y)$$ \hspace{1cm} (15a)

$$\dot{y} = -\beta \nabla_y g(x, y) - \left[ \nabla^2_{yy} g(x, y) \right]^{-1} \nabla^2_{xy} g(x, y) \dot{x}$$ \hspace{1cm} (15b)
and choose the constants $\alpha$ and $\beta$ appropriately, then there exists a Lyapunov function $V$ of the $x$- and $y$-dynamics that satisfies (C1) and (C2).

**Proof:** To highlight the intuition, we provide a constructive proof of this theorem. We first try $V_0 := f(x, y^*(x))$. To clarify, we can use $y^*(x)$ in a Lyapunov function but not in a dynamic to evolve a quantity. In this case, we have

$$
\dot{V}_0 = \langle \nabla_x f(x, y^*(x)), \dot{x} \rangle + \langle \nabla_y f(x, y^*(x)), \nabla_x y^*(x) \dot{x} \rangle
$$

$$
= \langle \nabla_x f(x, y^*(x)) + \nabla_x y^*(x)^\top \nabla_y f(x, y^*(x)), \dot{x} \rangle.
$$

Recall the definition in (7). Then we have

$$
\dot{V}_0 = -\alpha \langle T(x, y^*(x)), T(x, y) \rangle
$$

$$
\leq -\alpha \| T(x, y^*(x)) \|^2 + \alpha \| \nabla_x f(x, y) - \nabla_x f(x, y^*(x)) \| \| T(x, y^*(x)) \|
$$

$$
\leq -\alpha \| T(x, y^*(x)) \|^2 + \alpha L_f \| y - y^*(x) \| \| T(x, y^*(x)) \|
$$

$$
\leq -\frac{\alpha}{2} \| T(x, y^*(x)) \|^2 + \frac{\alpha L_f^2}{2} \| y - y^*(x) \|^2
$$

(16)

where (a) uses the Cauchy-Schwarz inequality, (b) follows from the $L_f$-Lipschitz continuity of $\nabla_x f(x, \cdot)$ established in Lemma 7, and (c) is due to the Young’s inequality.

To satisfy (C1), we have $\dot{V}_0 \leq 0$ only if $L_f \| y - y^*(x) \| \leq \| T(x, y^*(x)) \|$, thus, requiring the information of $\| y - y^*(x) \|$ — not doable without knowing $y^*(x)$.

Let us try to mitigate the term $\| y(x) - y^*(x) \|^2$ by defining the following new Lyapunov function:

$$
V := V_0 + \frac{1}{2} \| y - y^*(x) \|^2 = f(x, y^*(x)) + \frac{1}{2} \| y - y^*(x) \|^2
$$

(17)
which implies that

\[
\dot{V} = -\alpha \langle \mathcal{T}(x, y^*(x)), \mathcal{T}(x, y) \rangle + \langle y - y^*(x), \dot{y} - \nabla_x y^*(x) \dot{x} \rangle 
\]

\[
\leq \frac{\alpha}{2} \|\mathcal{T}(x, y^*(x))\|^2 + \frac{\alpha L_f^2}{2} \|y - y^*(x)\|^2 + \langle y - y^*(x), \dot{y} - \nabla_x y^*(x) \dot{x} \rangle 
\]

\[
\leq -\frac{\alpha}{2} \|\mathcal{T}(x, y^*(x))\|^2 - \left( \beta - \frac{\alpha L_f^2}{2} \right) \|y - y^*(x)\|^2 
\]

\[
+ \langle y - y^*(x), \dot{y} - \beta (y - y^*(x)) - \nabla_x y^*(x) \dot{x} \rangle 
\]

(19)

where \( \beta > 0 \) is a fixed constant. The first two terms in the RHS of (19) are non-positive given that \( \alpha \geq 0 \) and \( \beta \geq \alpha L_f^2/2 \), but the last term can be either positive or negative. To control the last term and thus ensure the descent of \( V(t) \), we are motivated to use a \( y \)-dynamic like

\[
\dot{y} \approx -\beta (y - y^*(x)) + \nabla_x y^*(x) \dot{x}. 
\]

(20)

To avoid using \( y^* \) in a dynamic, we approximate \( y - y^*(x) \) by \( \nabla_y g(x, y) \) and \( \nabla_x y^*(x) \) by (cf. (7a))

\[
\nabla_x y(x) := -\left[ \nabla^2_{yy} g(x, y) \right]^{-1} \nabla^2_{xy} g(x, y). 
\]

(21)

These choices lead to the \( y \)-dynamics:

\[
\dot{y} = -\beta \nabla_y g(x, y) + \nabla_x y(x) \dot{x}. 
\]

(22)

Although we approximate (20) by (22), next we will plug \( y \)-dynamics (22) into (19) and show that \( V \) satisfies (C1). Specifically, plugging (22) into (18) leads to

\[
\langle y - y^*(x), \dot{y} - \nabla_x y^*(x) \dot{x} \rangle = -\langle y - y^*(x), \beta \nabla_y g(x, y) - \nabla_x y(x) \dot{x} + \nabla_x y^*(x) \dot{x} \rangle. 
\]

(23)

As \( g(x, \cdot) \) is \( \mu_g \)-strongly convex by Assumption 2, we have

\[
\langle y - y^*(x), \nabla_y g(x, y) - \nabla_y g(x, y^*(x)) \rangle \geq \mu_g \|y - y^*(x)\|^2 
\]

(24)

where \( \nabla_y g(x, y^*(x)) = 0 \) as \( y^*(x) \) minimizes \( g(x, y) \).

Therefore, plugging (24) into (23), we have

\[
\langle y - y^*(x), \dot{y} - \nabla_x y^*(x) \dot{x} \rangle \leq -\langle y - y^*(x), (\nabla_x y^*(x) - \nabla_x y(x)) \dot{x} \rangle - \beta \mu_g \|y - y^*(x)\|^2 
\]

\[
\leq \|y - y^*(x)\| \|\nabla_x y^*(x) - \nabla_x y(x)\| \|\dot{x}\| - \beta \mu_g \|y - y^*(x)\|^2 
\]

\[
\leq \alpha B_x L_y \|y - y^*(x)\|^2 - \beta \mu_g \|y - y^*(x)\|^2 
\]

(25)

where the second inequality uses the Cauchy-Schwarz inequality, and the last inequality follows the bound \( B_x \) of \( \|\dot{x}\| \) and the Lipschitz constant \( L_y \) of \( \nabla_x y(x) \), both of which can be derived from Assumptions 1–3.

Now plugging (25) into (18), we have

\[
\dot{V} \leq -\frac{\alpha}{2} \|\mathcal{T}(x, y^*(x))\|^2 - \left( \beta \mu_g - \frac{\alpha L_f^2}{2} - \alpha B_x L_y \right) \|y - y^*(x)\|^2. 
\]

(26)
Now let us check (C1) and (C2). To ensure $\dot{V} \leq 0$ in (C1), we can set $\alpha \leq \frac{2\mu g \beta}{L_x^2 + 2B_x L_y}$. For (C2), we have $\dot{V} = 0$ if and only if $y = y^*(x)$ and $T(x, y^*(x)) = \nabla F(x) = 0$.

With the insights gained from the continuous-time update (15), our stochastic update (11) essentially discretizes time $t$ into iteration $k$, and replaces the first- and second-order derivatives in $\dot{x}$ and $\dot{y}$ by their recursive (variance-reduced) stochastic values in (12).

Remark 3 The key ingredient of our STABLE method is the design of the lower-level update on $y^k$, which leads to a more accurate stochastic estimate of $\nabla F(x^k)$. See a comparison of the $y$-update with other algorithms in Figure 1. In the update (11), we implement the SGD-like update for the upper-level variable $x^k$. With the lower-level $y^k$ update unchanged, it is easy to apply SGD-improvement techniques such as momentum and variance reduction, to accelerate the convergence of STABLE. This will help STABLE achieve state-of-the-art performance for stochastic bilevel optimization.

3. Convergence Analysis

In this section, we establish the convergence rate of our single-timescale STABLE algorithm. We will highlight the key steps of the proof and leave the detailed analysis in Appendix.

3.1. Main results

We first present the result of our algorithm when the upper-level function $F(x)$ is nonconvex in $x$.

Theorem 2 (Nonconvex) Under Assumptions 1–3, if we choose the stepsizes as

$$\beta_k \leq \min \left\{ \frac{1}{\sqrt{K}}, \frac{\mu g / L_g}{32(\mu g + L_g)} \right\}$$

(27a)

$$\alpha_k \leq \min \left\{ \beta_k, \frac{(c + 2C_s^2 C_y^2 / \mu^2_y)^{-1} + (c + 2C_s^2 / \mu^2_y)^{-1}}{\sqrt{K}}, \frac{\mu g L_y \beta_k / (\mu g + L_g)}{2(c + L_y^2)} \right\}$$

(27b)

and $\tau_k = \frac{1}{\sqrt{K}}$, then the iterates $\{x^k\}$ and $\{y^k\}$ satisfy

$$\mathbb{E} \left[ \|\nabla F(x^K)\|^2 \right] = \mathcal{O} \left( \frac{1}{\sqrt{K}} \right) \quad \text{and} \quad \mathbb{E} \left[ \|y^K - y^*(x^K)\|^2 \right] = \mathcal{O} \left( \frac{1}{\sqrt{K}} \right)$$

(28)

where $y^*(x^K)$ is the minimizer of the lower-level problem in (1b), and $c > 0$ is an absolute constant that is independent of the stepsizes $\alpha_k, \beta_k, \tau_k$ and the number of iterations $K$.

Theorem 2 implies that the convergence rate of STABLE to the stationary point of (1) is $\mathcal{O}(K^{-\frac{1}{2}})$. Since each iteration of STABLE only uses two samples (see Algorithm 1), the sample complexity to achieve an $\epsilon$-stationary point of (1) is $\mathcal{O}(\epsilon^{-2})$, which is on the same order of SGD’s sample complexity for the single-level nonconvex problems (Ghadimi and Lan, 2013), and significantly improves the state-of-the-art single-loop TTSA’s convergence rate $\mathcal{O}(\epsilon^{-2.5})$ (Hong et al., 2020). In addition, this convergence rate is not directly comparable to other recently developed bilevel optimization methods, e.g., (Ghadimi and Wang, 2018; Ji et al., 2020) since STABLE does not need the increasing batchsize nor double-loop. Regarding the sample complexity, however, STABLE improves over (Ghadimi and Wang, 2018; Ji et al., 2020) by at least the order of $\mathcal{O}(\log(\epsilon^{-1}))$. 

We next present the result in the strongly convex case. For the strong-convex case, we slightly modify the update of \( x^k \) in (11a) to

\[
x^{k+1} = \mathcal{P}_X \left( x^k - \alpha_k \left( \nabla_x f(x^k, y^k; \xi^k) - H^{k}_{xy} (H^{k}_{yy})^{-1} \nabla_y f(x^k, y^k; \xi^k) \right) \right)
\]

where \( \mathcal{P}_X \) denotes the projection on set \( X \).

We need the following additional assumption.

**Assumption 4 (strong convexity).** Function \( F(x) \) is \( \mu \)-strongly convex in \( x \), that is, \( \nabla_x^2 F(x) \succeq \mu I \).

**Theorem 3 (Strongly convex)** Under Assumptions 1–4, if we choose the stepsizes as

\[
\beta_k = \tau_k \leq \min \left\{ \frac{\mu_y}{32 (\mu_y + L^y)}, \frac{1}{K_0 + \bar{k}} \right\}
\]

\[
\alpha_k \leq \min \left\{ \sqrt{\frac{\mu_y L_y}{4c (\mu_y + L^y) + 2L^2_y (\mu_y + L^y)}}, \frac{1}{\sqrt{4c}}, \frac{\mu_y^2}{8 C^2_{g^2 y} C^2_{f^2}}, \frac{\mu_y^2}{8 C^2_{f^2}} \right\} \beta_k
\]

where \( K_0 > 0 \) is a sufficiently large constant and \( c > 0 \) is an absolute constant that is independent of the stepsizes \( \alpha_k, \beta_k, \tau_k \), then the iterates \( \{x^k\} \) and \( \{y^k\} \) satisfy

\[
\mathbb{E} \left[ \| x^k - x^* \|^2 \right] = \mathcal{O} \left( \frac{1}{k} \right) \quad \text{and} \quad \mathbb{E} \left[ \| y^k - y^*(x^k) \|^2 \right] = \mathcal{O} \left( \frac{1}{k} \right)
\]

where the solution \( x^* \) is defined as \( x^* = \arg\min_{x \in X} F(x) \) and \( y^*(x^k) \) is the minimizer of the lower-level problem in (1b).

Theorem 3 implies that to achieve an \( \epsilon \)-optimal solution for both the lower-level and upper-level problems, the sample complexity of STABLE is \( \mathcal{O} (\epsilon^{-1}) \). This complexity is on the same order of SGD’s complexity for the single-level strongly convex problems (Ghadimi and Lan, 2013), and improves the state-of-the-art single-loop TTSA’s sample complexity \( \mathcal{O} (\epsilon^{-2}) \) for an \( \epsilon \)-optimal upper-level solution and \( \mathcal{O} (\epsilon^{-1.5}) \) for an \( \epsilon \)-optimal lower-level solution (Hong et al., 2020). Compared with double-loop bilevel algorithms in this strong-convex case, STABLE also improves over the BSA’s query complexity \( \mathcal{O} (\epsilon^{-1}) \) in terms of the stochastic upper-level function and \( \mathcal{O} (\epsilon^{-2}) \) in terms of the stochastic lower-level function (Ghadimi and Wang, 2018).

### 3.2. Proof sketch

Next we highlight the key steps of the proof towards Theorem 2. The proof for the strongly convex case in Theorem 3 will follow similar steps.

For simplicity of the convergence analysis, we define the following Lyapunov function

\[
\psi^k := F(x^k) + \| y^k - y^*(x^k) \|^2 + \| H^{k}_{yy} - \nabla^2_{yy} g(x^k, y^k) \|^2 + \| H^{k}_{xy} - \nabla^2_{xy} g(x^k, y^k) \|^2
\]

which mimics the continuous-time Lyapunov function (17) for the deterministic problem.

Similar to the ODE analysis, we first quantify the difference between two Lyapunov functions as

\[
\psi^{k+1} - \psi^k = F(x^{k+1}) - F(x^k) + \| y^{k+1} - y^*(x^{k+1}) \|^2 - \| y^k - y^*(x^k) \|^2
\]

\[
+ \| H^{k+1}_{yy} - \nabla^2_{yy} g(x^{k+1}, y^{k+1}) \|^2 - \| H^{k}_{yy} - \nabla^2_{yy} g(x^k, y^k) \|^2
\]

\[
+ \| H^{k+1}_{xy} - \nabla^2_{xy} g(x^{k+1}, y^{k+1}) \|^2 - \| H^{k}_{xy} - \nabla^2_{xy} g(x^k, y^k) \|^2.
\]
The difference in (33) consists of four difference terms: the first term quantifies the descent of the upper-level objective functions; the second term characterizes the descent of the lower-level optimization errors; and, the third and fourth terms measure the estimation error of the second-order quantities. We will bound them, respectively, in the ensuing lemmas.

We will first analyze the descent of the upper-level objective in the next lemma.

**Lemma 4 (Descent of upper level)** Suppose Assumptions 1–3 hold. The sequence of \( x^k \) satisfies

\[
\mathbb{E}[F(x^{k+1})] - \mathbb{E}[F(x^k)] \leq -\frac{\alpha_k}{2}\mathbb{E}[\|
abla F(x^k)\|^2] + \frac{L_F}{2}\mathbb{E}[\|x^{k+1} - x^k\|^2] + \alpha_k L_f^2 \mathbb{E}[\|y^k - y^*(x^k)\|^2] \\
+ \frac{2C^2_{g_{xy}} C^2_{f_y} \alpha_k}{\mu_y^2} \mathbb{E}[\|H_{yy}^k - \nabla_{yy}^2 g(x^k, y^k)\|^2] \\
+ \frac{2C^2_{f_y} \alpha_k}{\mu_y^2} \mathbb{E}[\|H_{xy}^k - \nabla_{xy}^2 g(x^k, y^k)\|^2]
\]

(34)

where \( L_f, L_F \) are defined in Lemma 7 of Appendix, and \( C_{g_{xy}} \) is the projection radius in (12a).

Lemma 4 implies that the descent of the upper-level objective functions depends on the error of the lower-level variable \( y^k \), and the estimation errors of \( H_{yy}^k \) and \( H_{xy}^k \). We will next analyze the error of the lower-level variable, which is the key step to improving the existing results.

**Lemma 5 (Error of lower level)** Suppose that Assumptions 1–3 hold, and \( y^{k+1} \) is generated by running iteration (11) given \( x^k \). If we choose \( \beta_k \leq \frac{\mu_y}{2 \mu_y + L_y} \), then \( y^{k+1} \) satisfies

\[
\mathbb{E}\left[\|y^*(x^{k+1}) - y^{k+1}\|^2 | \mathcal{F}^k\right] \leq \left(1 - \frac{\mu_y L_y \beta_k}{\mu_y + L_y} + \frac{c\alpha_k^2}{\beta_k}\right)\|y^k - y^*(x^k)\|^2 + \left(1 + \frac{\mu_y L_y \beta_k}{\mu_y + L_y}\right)\beta_k^2 \sigma_{g_{yy}}^2 \\
+ \frac{c\alpha_k^2}{\beta_k} + \mathbb{E}\left[\|H_{yy}^k - \nabla_{yy}^2 g(x^k, y^k)\|^2 | \mathcal{F}^k\right] \frac{c\alpha_k^2}{\beta_k} \\
+ \mathbb{E}\left[\|H_{xy}^k - \nabla_{xy}^2 g(x^k, y^k)\|^2 | \mathcal{F}^k\right] \frac{c\alpha_k^2}{\beta_k}.
\]

(35)

Roughly speaking, Lemma 5 implies that if the stepsizes \( \alpha_k \) and \( \beta_k \) and the estimation errors of \( H_{yy}^k \) and \( H_{xy}^k \) are decreasing fast enough, then the error of \( y^{k+1} \) will also decrease.

Since the RHS of both Lemmas 4 and 5 critically depend on the quality of \( H_{yy}^k \) and \( H_{xy}^k \), we will next build upon the results in (Chen et al., 2020, Lemma 2) to analyze the estimation errors.

**Lemma 6 (Estimation errors of \( H_{yy}^k \) and \( H_{xy}^k \))** Suppose Assumptions 1–3 hold, and \( H_{xy}^k \) and \( H_{yy}^k \) are generated by running (12). The mean square error of \( H_{yy}^k \) satisfies

\[
\mathbb{E}\left[\|H_{yy}^k - \nabla_{yy}^2 g(x^k, y^k)\|^2 | \mathcal{F}^k\right] \leq \left(1 - \tau_k\right)^2 \|H_{yy}^{k-1} - \nabla_{yy}^2 g(x^{k-1}, y^{k-1})\|^2 + 2\tau_k^2 \sigma_{g_{yy}}^2 \\
+ 2(1 - \tau_k)^2 (L_{g_{yy}}^2 + L_{g_{yy}}^2) \|x^k - x^{k-1}\|^2 + 2(1 - \tau_k)^2 (L_{g_{yy}}^2 + L_{g_{yy}}^2) \|y^k - y^{k-1}\|^2
\]

(36)

where the constants \( L_{g_{xy}}, L_{g_{yy}}, \tilde{L}_{g_{xy}}, \tilde{L}_{g_{yy}}, \sigma_{g_{xy}}, \sigma_{g_{yy}} \) are defined in Assumptions 1 and 3. And likewise, the mean square error of \( H_{xy}^k \) satisfies

\[
\mathbb{E}\left[\|H_{xy}^k - \nabla_{xy}^2 g(x^k, y^k)\|^2 | \mathcal{F}^k\right] \leq \left(1 - \tau_k\right)^2 \|H_{xy}^{k-1} - \nabla_{xy}^2 g(x^{k-1}, y^{k-1})\|^2 + 2\tau_k^2 \sigma_{g_{yy}}^2 \\
+ 2(1 - \tau_k)^2 (L_{g_{yy}}^2 + L_{g_{yy}}^2) \|x^k - x^{k-1}\|^2 + 2(1 - \tau_k)^2 (L_{g_{yy}}^2 + L_{g_{yy}}^2) \|y^k - y^{k-1}\|^2.
\]

(37)
Intuitively, the update of $x^k$ is bounded and so is the update of $y^k$, and thus $\|x^k - x^{k-1}\|^2 = O(\alpha_k^2)$ and $\|y^k - y^{k-1}\|^2 = O(\beta_k^2)$. Plugging them into the RHS of Lemma 6, it suggests that if the stepsizes $\alpha_k, \beta_k, \tau_k$ are decreasing, then the estimation errors of $H_{xy}^k$ and $H_{yy}^k$ also decrease.

Applying Lemmas 4–6 to (33) and rearranging terms, we will be able to get

$$E[V^{k+1}] - E[V^k] \leq -c_1 E[\|y^k - y^*(x^k)\|^2] - c_2 E[\|\nabla F(x^k)\|^2] + c_3$$

(38)

where the constants are $c_1 = O(\beta_k), c_2 = O(\alpha_k)$ and $c_3 = O(\alpha_k^2 + \beta_k^2 + \tau_k^2)$. By choosing stepsizes $\alpha_k, \beta_k, \tau_k$ as (27) and telescoping both sides of (38), we obtain the main results in Theorem 2.

4. Conclusions

This paper develops a new stochastic gradient estimator for bilevel optimization problems. When running SGD on top of this stochastic bilevel gradient, the resultant STABLE algorithm runs in a single loop fashion, and uses a single-timescale update. In both the nonconvex and strongly-convex cases, STABLE matches the sample complexity of SGD for single-level stochastic problems. One possible extension is to apply SGD-improvement techniques to accelerate STABLE, which helps STABLE achieve state-of-the-art performance for bilevel problems. Another natural extension is to apply our bilevel optimization method to the general two-timescale stochastic approximation case, in a similar fashion to (Dalal et al., 2018; Kaledin et al., 2020). Improving the sample complexity of such general case can be of great interest to the reinforcement learning community.

Appendix A. Auxiliary Lemmas

In this appendix, we first present some auxiliary lemmas that will be used frequently in the proof.

**Lemma 7 ((Ghadimi and Wang, 2018, Lemma 2.2))** Under Assumptions 1 and 2, we have

\[
\|\nabla_x f(x, y^*(x)) - \nabla_x f(x, y)\| \leq L_f \|y^*(x) - y\| \tag{39a}
\]

\[
\|\nabla F(x_1) - \nabla F(x_2)\| \leq L_F \|x_1 - x_2\| \tag{39b}
\]

\[
\|y^*(x_1) - y^*(x_2)\| \leq L_y \|x_1 - x_2\| \tag{39c}
\]

and the constants \(L_f, L_y, L_F\) are defined as

\[
L_f := L_{f_x} + \frac{C_{g_y} L_{f_y}}{\mu_g} + \frac{C_{f_y}}{\mu_g} \left( L_{f_{xy}} + \frac{C_{g_x} L_{g_{yy}}}{\mu_g} \right), \quad L_y := \frac{C_{g_y}}{\mu_g}
\]

\[
L_F := \bar{L}_{f_x} + \frac{C_{g_y} (\bar{L}_{f_y} + L_f)}{\mu_g} + \frac{C_{f_y}}{\mu_g} \left( \bar{L}_{f_{xy}} + \frac{C_{g_x} \bar{L}_{g_{yy}}}{\mu_g} \right)
\]

where the constants are defined in Assumptions 1–3.
Appendix B. Proof of Proposition 1

Proof: Define the Jacobian matrix

\[
\nabla_x y(x) = \begin{bmatrix}
\frac{\partial}{\partial x_1} y_1(x) & \cdots & \frac{\partial}{\partial x_d} y_1(x) \\
\vdots & \ddots & \vdots \\
\frac{\partial}{\partial x_1} y_d(x) & \cdots & \frac{\partial}{\partial x_d} y_d(x)
\end{bmatrix}.
\]

By the chain rule, it follows that

\[
\nabla F(x) := \nabla_x f(x, y^*(x)) + \nabla_x y^*(x)^\top \nabla_y f(x, y^*(x)).
\]

(40)

The minimizer \(y^*(x)\) satisfies

\[
\nabla_y g(x, y^*(x)) = 0, \quad \text{thus } \nabla_x (\nabla_y g(x, y^*(x))) = 0.
\]

(41)

By the chain rule again, it follows that

\[
\nabla_{xx}^2 g(x, y^*(x)) + \nabla_x y^*(x)^\top \nabla_{yy}^2 g(x, y^*(x)) = 0.
\]

By Assumption 2, \(\nabla_{yy}^2 g(x, y^*(x))\) is invertible, so

\[
\nabla_x y^*(x)^\top := -\nabla_{xx}^2 g(x, y^*(x)) \left[\nabla_{yy}^2 g(x, y^*(x))\right]^{-1}.
\]

(42)

By substituting (42) into (40), we arrive at (7).

Appendix C. Proof of Lemma 4

Proof: Now we turn to analyze the update of \(x\). For convenience, we define the update in (11a) as

\[
x^{k+1} = x^k - \alpha_k \bar{h}_f^k \quad \text{with} \quad \bar{h}_f^k := \nabla_x f \left(x^k, y^k; \xi^k\right) - H^k_{f,y} (H^k_{y,y})^{-1} \nabla_y f \left(x^k, y^k; \xi^k\right)
\]

(43)

Using the smoothness of \(F(x^k)\) obtained from Lemma 7, we have

\[
\mathbb{E}[F(x^{k+1})|\mathcal{F}^k] \
\leq F(x^k) + \mathbb{E}[\|\nabla F(x^k)\|] + \frac{L_F}{2} \mathbb{E}[\|x^{k+1} - x^k\|^2|\mathcal{F}^k] \
= F(x^k) - \alpha_k \langle \nabla F(x^k), \mathbb{E}[\bar{h}_f^k|\mathcal{F}^k]\rangle + \frac{L_F}{2} \mathbb{E}[\|x^{k+1} - x^k\|^2|\mathcal{F}^k] \
= F(x^k) - \alpha_k \|\nabla F(x^k)\|^2 + \alpha_k \langle \nabla F(x^k), \nabla F(x^k) - \mathbb{E}[\bar{h}_f^k|\mathcal{F}^k]\rangle + \frac{L_F}{2} \mathbb{E}[\|x^{k+1} - x^k\|^2|\mathcal{F}^k] \
\leq F(x^k) - \left(\alpha_k - \frac{\alpha_k^2}{4\gamma_k}\right) \|\nabla F(x^k)\|^2 + \gamma_k \|\nabla F(x^k) - \mathbb{E}[\bar{h}_f^k|\mathcal{F}^k]\|^2 + \frac{L_F}{2} \mathbb{E}[\|x^{k+1} - x^k\|^2|\mathcal{F}^k]
\]

(44)

where the last inequality uses Young’s inequality with parameter \(\gamma_k\). We choose \(\gamma_k = \alpha_k/2\).
The approximation error of $\tilde{h}_f^k$ can be bounded by

$$
\|\nabla F(x^k) - E[\tilde{h}_f^k|\mathcal{F}^k]\|^2 
\leq 2\|\nabla F(x^k) - \nabla f(x^k, y^k)\|^2 + 2E[\|\nabla f(x^k, y^k) - \nabla E[\tilde{h}_f^k]\|^2|\mathcal{F}^k]
\leq 2L_f^2 \|y^k - y^*(x^k)\|^2 + 2E[\|\nabla f(x^k, y^k) - \nabla E[\tilde{h}_f^k]\|^2|\mathcal{F}^k]
\leq 2L_f^2 \|y^k - y^*(x^k)\|^2 + 2\|H_{yy}^{-1}H_{xy}^k - H_{xy}(x^k, y^k)\|^2\|\nabla y f(x^k, y^k)\|^2
\leq 2L_f^2 \|y^k - y^*(x^k)\|^2 + \frac{4C_g^2}{\mu_g}E[\|H_{yy} - H_{xy}(x^k, y^k)\|^2|\mathcal{F}^k] + \frac{4C_f^2}{\mu_g}E[\|H_{xy}^k - H_{xy}(x^k, y^k)\|^2|\mathcal{F}^k]
$$

where (a) follows from Lemma 7, (b) uses the fact that

$$
E[\tilde{h}_f^k|\mathcal{F}^k] = \nabla f(x^k, y^k) - (H_{yy}^{-1}H_{xy}^k)\nabla y f(x^k, y^k)
$$

and (c) follows the same steps of (56) and Assumption 3. Plugging (45) into (44) and taking expectation over all the randomness lead to the lemma.

### Appendix D. Proof of Lemma 5

**Proof:** We start by decomposing the error of the lower level variable as

$$
E\left[\|y^{k+1} - y^*(x^{k+1})\|^2|\mathcal{F}^k\right] = E\left[\|y^k - \beta_k h_g^k - y^*(x^k) + y^*(x^k) - y^*(x^{k+1}) - (H_{yy}^k - 1)(H_{xy}^k)^\top(x^{k+1} - x^k)\|^2|\mathcal{F}^k]\right]
\leq (1 + \epsilon)E\left[\|y^k - \beta_k h_g^k - y^*(x^k)\|^2|\mathcal{F}^k\right] + (1 + \epsilon^{-1})E\left[\|y^*(x^k) - y^*(x^{k+1}) - (H_{yy}^k - 1)(H_{xy}^k)^\top(x^{k+1} - x^k)\|^2|\mathcal{F}^k\right].
$$

The upper bound of $I_1$ can be derived as

$$
I_1 = \|y^k - y^*(x^k)\|^2 - 2\beta_k E[(y^k - y^*(x^k), h_g^k)|\mathcal{F}^k] + \beta_k^2 E[\|h_g^k\|^2|\mathcal{F}^k]
\leq \|y^k - y^*(x^k)\|^2 - 2\beta_k \langle y^k - y^*(x^k), \nabla y g(x^k, y^k) \rangle + \beta_k^2 \|\nabla y g(x^k, y^k)\|^2 + \beta_k^2 \sigma_g^2
\leq \left(1 - \frac{2\mu_g L_g}{\mu_g + L_g} \beta_k\right) \|y^k - y^*(x^k)\|^2 + \beta_k \left(\beta_k - \frac{2}{\mu_g + L_g}\right) \|\nabla y g(x^k, y^k)\|^2 + \beta_k^2 \sigma_g^2
$$

where (a) comes from the fact that $\text{Var}[X] = E[X^2] - E[X]^2$, (b) follows from the $\mu_g$-strong convexity and $L_g$ smoothness of $g(x, y)$ (Nesterov, 2013, Theorem 2.1.11), and (c) follows from the choice of stepsize $\beta_k \leq \frac{\mu_g / L_g}{32(\mu_g + L_g)} \leq \frac{2}{\mu_g + L_g}$ in (27a).
The upper bound of $I_2$ can be derived as

$$I_2 = \mathbb{E} \left[ \left\| y^* (x^k) - y^* (x^{k+1}) - (H_{yy}^k)^{-1} H_{xy}^k (x^{k+1} - x^k) \right\|^2 | \mathcal{F}^k \right]$$

$$\leq 3 \mathbb{E} \left[ \left\| y^* (x^{k+1}) - y^* (x^k) - \nabla x y^* (x^k) (x^{k+1} - x^k) \right\|^2 | \mathcal{F}^k \right]$$

$$+ 3 \mathbb{E} \left[ \left\| \left( \nabla x y^* (x^k) - H_{yy} (x^k, y^k)^{-1} H_{xy} (x^k, y^k)^\top \right) (x^{k+1} - x^k) \right\|^2 | \mathcal{F}^k \right]$$

$$+ 3 \mathbb{E} \left[ \left\| H_{yy} (x^k, y^k)^{-1} H_{xy} (x^k, y^k)^\top - (H_{yy}^k)^{-1} (H_{xy}^k)^\top \right\| (x^{k+1} - x^k) \right\|^2 | \mathcal{F}^k \right]. \quad (49)$$

We first bound the first approximation error in the RHS of (49) by

$$\left\| y^* (x^{k+1}) - y^* (x^k) - \nabla x y^* (x^k) (x^{k+1} - x^k) \right\|^2$$

$$= \left\| \int_0^1 \nabla x y^* (x^k + t(x^{k+1} - x^k)) (x^{k+1} - x^k) dt - \nabla x y^* (x^k) (x^{k+1} - x^k) \right\|^2$$

$$\leq \int_0^1 \left\| \nabla x y^* (x^k + t(x^{k+1} - x^k)) - \nabla x y^* (x^k) \right\|^2 \| x^{k+1} - x^k \|^2 dt \leq \frac{T^2}{2} \| x^{k+1} - x^k \|^4 \quad (50)$$

where the first inequality follows from the Cauchy-Schwarz inequality, and the second inequality follows from the $L_y$-Lipschitz continuity of $\nabla x y^* (x)$ in Lemma 7.

Next we bound the second term in the RHS of (49) as

$$\mathbb{E} \left[ \left\| \left( \nabla x y^* (x^k) - H_{yy} (x^k, y^k)^{-1} H_{xy} (x^k, y^k)^\top \right) (x^{k+1} - x^k) \right\|^2 | \mathcal{F}^k \right]$$

$$\leq \mathbb{E} \left[ \left\| \nabla x y^* (x^k) - H_{yy} (x^k, y^k)^{-1} H_{xy} (x^k, y^k)^\top \right\|^2 \| x^{k+1} - x^k \|^2 | \mathcal{F}^k \right] \quad (51)$$

and likewise, the third term of (49) as

$$\mathbb{E} \left[ \left\| H_{yy} (x^k, y^k)^{-1} H_{xy} (x^k, y^k)^\top - (H_{yy}^k)^{-1} (H_{xy}^k)^\top \right\| (x^{k+1} - x^k) \right\|^2 | \mathcal{F}^k \right]$$

$$\leq \mathbb{E} \left[ \left\| H_{yy} (x^k, y^k)^{-1} H_{xy} (x^k, y^k)^\top - (H_{yy}^k)^{-1} (H_{xy}^k)^\top \right\|^2 \| x^{k+1} - x^k \|^2 | \mathcal{F}^k \right]. \quad (52)$$

We then bound the approximation error of $H_{yy} (x^k, y^k)^{-1} H_{xy} (x^k, y^k)^\top$ in (51) by

$$\left\| \nabla x y^* (x^k) - H_{yy} (x^k, y^k)^{-1} H_{xy} (x^k, y^k)^\top \right\|^2$$

$$= \left\| H_{yy} \left( x^k, y^* (x^k) \right)^{-1} H_{xy} \left( x^k, y^* (x^k) \right)^\top - H_{yy} (x^k, y^k)^{-1} H_{xy} (x^k, y^k)^\top \right\|^2$$

$$= \left\| H_{yy} \left( x^k, y^* (x^k) \right)^{-1} H_{xy} \left( x^k, y^* (x^k) \right)^\top - H_{yy} (x^k, y^k)^{-1} H_{xy} \left( x^k, y^* (x^k) \right)^\top \right\|^2$$

$$+ \left\| H_{yy} (x^k, y^k)^{-1} H_{xy} \left( x^k, y^* (x^k) \right)^\top - H_{yy} (x^k, y^k)^{-1} H_{xy} (x^k, y^k)^\top \right\|^2$$

$$\leq 2 C_{g_{yy}}^2 \left\| H_{yy} \left( x^k, y^* (x^k) \right)^{-1} - H_{yy} (x^k, y^k)^{-1} \right\|^2 + \frac{2}{\mu_g^2} \left\| H_{xy} \left( x^k, y^* (x^k) \right) - H_{xy} (x^k, y^k) \right\|^2 \quad (53)$$
where the inequality follows from \( \|H_{xy}(x, y)\| \leq C_{g_{xy}} \) and \( H_{yy}(x, y) \geq \mu_g I \).

Note that
\[
\|H_{yy}(x^k, y^k(-1)^{-1} - H_{yy}(x^k, y^k)^{-1}\|^2 \\
= \|H_{yy}(x^k, y^k(-1)^{-1} (H_{yy}(x^k, y^k) - H_{yy}(x^k, y^k)) H_{yy}(x^k, y^k)^{-1}\|^2 \\
\leq \|H_{yy}(x^k, y^k(-1)^{-1}\|^2 \|H_{yy}(x^k, y^k) - H_{yy}(x^k, y^k)^{-1}\|^2 \\
\leq \frac{1}{\mu_g}\|H_{yy}(x^k, y^k) - H_{yy}(x^k, y^k)^{-1}\|^2 \\
\] (54)

where the last inequality follows from \( H_{yy}(x, y) \geq \mu_g I \).

Therefore, we have
\[
\left\|\nabla_x y^*(x^k) - H_{yy}(x^k, y^k)^{-1}H_{xy}(x^k, y^k)^{-1}\right\|^2 \\
\leq \frac{2C_{g_{xy}}}{\mu_g}\|H_{yy}(x^k, y^k)^{-1} - H_{yy}(x^k, y^k)^{-1}\|^2 + \frac{2}{\mu_g}\|H_{xy}(x^k, y^k) - H_{xy}(x^k, y^k)^{-1}\|^2. \\
\] (55)

Following the steps towards (55), we bound the error of \((H_{yy}^{-1})^T(x^k) = H_{xy}^k \times (x^k)^T \in (52)\) by
\[
\left\|(H_{yy}(x^k)^{-1}(H_{xy}(x^k)^{-1} - H_{yy}(x^k, y^k)^{-1}H_{xy}(x^k, y^k)^{-1}\right\|^2 \\\n= \left\|(H_{yy}(x^k)^{-1}(H_{xy}(x^k)^{-1} + H_{yy}(x^k, y^k)^{-1}(H_{xy}(x^k, y^k)^{-1} - H_{yy}(x^k, y^k)^{-1}H_{xy}(x^k, y^k)^{-1}\right\|^2 \\\n\leq 2\left\|(H_{yy}(x^k)^{-1}(H_{xy}(x^k)^{-1} - H_{yy}(x^k, y^k)^{-1}(H_{xy}(x^k, y^k)^{-1}\right\|^2 \\\n+ \left\|H_{yy}(x^k, y^k)^{-1}(H_{xy}(x^k, y^k)^{-1} - H_{yy}(x^k, y^k)^{-1}H_{xy}(x^k, y^k)^{-1}\right\|^2 \\\n\leq \frac{2C_{g_{xy}}}{\mu_g}\|H_{yy}(x^k, y^k)\|^2 + \frac{2}{\mu_g}\|H_{xy}(x^k, y^k)\|^2 \\
\] (56)

where the second inequality follows from \( \|H_{xy}(x, y)\| \leq C_{g_{xy}} \) and \( H_{yy}(x, y) \geq \mu_g I \).

Plugging (50)-(56) back to (49), we have
\[
I_2 \leq \frac{3L^2}{2}E[|x^{k+1} - x^k|^2|F^k] + \frac{6C_{g_{xy}}}{\mu_g}\|H_{yy}(x^k, y^k)^{-1} - H_{yy}(x^k, y^k)^2E[|x^{k+1} - x^k|^2|F^k] \\
+ \frac{6}{\mu_g}\|H_{xy}(x^k, y^k)^{-1} - H_{xy}(x^k, y^k)^2E[|x^{k+1} - x^k|^2|F^k] \\
+ \frac{6C_{g_{xy}}}{\mu_g}E[|H_{yy}(x^k, y^k)|^2|x^{k+1} - x^k|^2|F^k] \\
+ \frac{6}{\mu_g}E[|H_{xy}(x^k, y^k)|^2|x^{k+1} - x^k|^2|F^k]. \\
\] (57)
Using the Lipschitz continuity of $H_{xy}(x, y)$ and $H_{yy}(x, y)$ in Assumption 1, from (57), we have
\begin{align*}
I_2 &\leq \frac{3L_y^2}{2} \mathbb{E}[\|x^{k+1} - x^k\|^4 | \mathcal{F}^k] + \frac{6}{\mu_g} \left( \frac{C_{gxy}^2 L_{gvy}}{\mu_g^2} + L_{gxy} \right) \|y^k - y^*(x^k)\|^2 \mathbb{E}[\|x^{k+1} - x^k\|^2 | \mathcal{F}^k] \\
&\quad + \frac{6C_{gxy}^2}{\mu_g^4} \mathbb{E}[\|H_{yy}^k - H_{yy}(x^k, y^k)\|^2 \|x^{k+1} - x^k\|^2 | \mathcal{F}^k] \\
&\quad + \frac{6}{\mu_g^4} \mathbb{E}[\|H_{xy}^k - H_{xy}(x^k, y^k)\|^2 \|x^{k+1} - x^k\|^2 | \mathcal{F}^k].
\end{align*}
(58)

For any $p = 2, 4$, we next analyze quantity $\mathbb{E}[\|x^{k+1} - x^k\|^{p} | \mathcal{F}^k]$ in (58). Recall the simplified update (43). Therefore, we have $\|x^{k+1} - x^k\| = \alpha_k \|\hat{x}^k\|$ and
\begin{align*}
\|\hat{x}^k\| &= \|\nabla_x f(x^k, y^k; \xi^k) - (H_{yy}^k)^{-1} H_{xy}^k \nabla_y f(x^k, y^k; \xi^k)\| \\
&\leq \|\nabla_x f(x^k, y^k; \xi^k)\| + \| (H_{yy}^k)^{-1} H_{xy}^k \nabla_y f(x^k, y^k; \xi^k)\| \\
&\leq (a) \|\nabla_x f(x^k, y^k; \xi^k)\| + \frac{C_{gxy}}{\mu_g} \|\nabla_y f(x^k, y^k; \xi^k)\|
\end{align*}
(59)

where (a) follows from the upper and lower projections of $H_{xy}^k$ and $H_{yy}^k$ in (12). Therefore, for $p = 2, 4$, we have
\begin{align*}
\mathbb{E}[\|\hat{h}_x^k\|^p | \mathcal{F}^k, H_{xy}^k, H_{yy}^k] &\leq 2^{p-1} \mathbb{E}\left[ \|\nabla_x f(x^k, y^k; \xi^k)\|^p | \mathcal{F}^k, H_{xy}^k, H_{yy}^k \right] \\
&\quad + 2^{p-1} \left( \frac{C_{gxy}}{\mu_g} \right)^{p} \mathbb{E}\left[ \|\nabla_y f(x^k, y^k; \xi^k)\|^p | \mathcal{F}^k, H_{xy}^k, H_{yy}^k \right] \\
&\leq 2^{p-1} \left( C_{f_x}^p + \left( \frac{C_{gxy}}{\mu_g} \right)^{p} C_{f_y}^p \right)
\end{align*}
(60)

where the last inequality from Assumption 3. And thus
\begin{align*}
\mathbb{E}\left[ \|x^{k+1} - x^k\|^p | \mathcal{F}^k, H_{xy}^k, H_{yy}^k \right] &\leq 2^{p-1} \left( C_{f_x}^p + \left( \frac{C_{gxy}}{\mu_g} \right)^{p} C_{f_y}^p \right) \alpha_k^p.
\end{align*}
(61)

Plugging (61) into (58), we have
\begin{align*}
I_2 &\leq 12L_y^2 \left( C_{f_x}^4 + \left( \frac{C_{gxy}}{\mu_g} \right)^{4} C_{f_y}^4 \right) \alpha_k^4 \\
&\quad + \frac{12}{\mu_g^2} \left( \frac{C_{gxy}^2 L_{gvy}}{\mu_g^2} + L_{gxy} \right) \left( C_{f_x}^2 + \left( \frac{C_{gxy}}{\mu_g} \right)^{2} C_{f_y}^2 \right) \|y^k - y^*(x^k)\|^2 \alpha_k^2 \\
&\quad + \frac{12C_{gxy}}{\mu_g^4} \left( C_{f_x}^2 + \left( \frac{C_{gxy}}{\mu_g} \right)^{2} C_{f_y}^2 \right) \mathbb{E}[\|H_{xy}^k - H_{xy}(x^k, y^k)\|^2 | \mathcal{F}^k] \alpha_k^2 \\
&\quad + \frac{12}{\mu_g^4} \left( C_{f_x}^2 + \left( \frac{C_{gxy}}{\mu_g} \right)^2 C_{f_y}^2 \right) \mathbb{E}[\|H_{yy}^k - H_{yy}(x^k, y^k)\|^2 | \mathcal{F}^k] \alpha_k^2.
\end{align*}
(62)
Now let us define the constants as
\[ \tilde{c}_1 := \max \left\{ 12L_y^2 \left( C_{f_x}^4 + \left( \frac{C_{g_{xy}}}{\mu_y} \right)^4 C_{f_y}^4 \right), \frac{12}{\mu_y^2} \left( \frac{C_{g_{xy}}}{\mu_y} \right)^2 + L_{g_{xy}} \right\} \]
\[ \tilde{c}_2 := \frac{2}{\mu_y + L_g} \left( \frac{\mu_y + L_g}{\mu_y L_g} \right), \quad c := \tilde{c}_1 \tilde{c}_2. \]

Plugging the upper bounds of \( I_1 \) in (48) and \( I_2 \) in (62) into (47) with \( \epsilon = \frac{\mu_y L_g}{\mu_y + L_g} \beta^k \), we have
\[
\mathbb{E} \left[ \left\| y^{k+1} - y^* (x^{k+1}) \right\|^2 \right] \leq \left( 1 - \frac{\mu_y L_g}{\mu_y + L_g} \beta^k \right) \left\| y^k - y^* (x^k) \right\|^2 + \left( 1 + \frac{\mu_y L_g}{\mu_y + L_g} \beta^k \right) \beta_k^2 \sigma_y^2 + \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k}{\beta_k} \]
\[
+ \tilde{c}_1 \tilde{c}_2 \mathbb{E} \left[ \left\| H_{xy}^k - H_{xy} (x^k, y^k) \right\|^2 \right] \frac{\alpha_k}{\beta_k} \]
where we have used the fact that
\[
\left( 1 + \frac{\mu_y L_g}{\mu_y + L_g} \beta^k \right) \left( 1 - \frac{2\mu_y L_g}{\mu_y + L_g} \beta^k \right) \leq 1 - \frac{\mu_y L_g}{\mu_y + L_g} \beta^k
\]
\[
\left( 1 + \frac{\mu_y L_g}{\mu_y + L_g} \beta_k \right)^{-1} \leq \frac{1}{\beta_k} \left( \frac{2}{\mu_y + L_g} + \frac{\mu_y + L_g}{\mu_y L_g} \right) = \frac{\tilde{c}_2}{\beta_k}
\]
where the last inequality uses \( \beta_k \leq \frac{2}{\mu_y + L_g} \) in (27a). The proof is complete by defining \( c := \tilde{c}_1 \tilde{c}_2. \)

\section*{Appendix E. Proof of Lemma 6}
\textbf{Proof:} Recall that \( g(x, y) = \mathbb{E}_\phi [g(x, y, \phi)] \). We only have access to the stochastic estimates of \( \nabla_{xy}^2 g(x, y), \nabla_{yy}^2 g(x, y) \), that is
\[
h_{yy}^k (\phi) := \nabla_{yy}^2 g \left( x^k, y^k; \phi \right), \quad h_{xy}^k (\phi) := \nabla_{xy}^2 g \left( x^k, y^k; \phi \right). \quad (64)
\]
For notational brevity in the analysis, we define
\[
H_{xy} (x, y) := \nabla_{xy}^2 g(x, y), \quad H_{yy} (x, y) := \nabla_{yy}^2 g(x, y). \quad (65)
\]
and rewrite the update of (12) as
\[
H_{xy}^k := P_{x: \|x\| \leq C_{g_{xy}}} \left\{ \tilde{H}_{xy}^k \right\} \quad \text{with} \quad \tilde{H}_{xy}^k := (1 - \tau_k) (H_{xy}^{k-1} - h_{xy}^{k-1} (\phi^k)) + h_{xy}^k (\phi^k) \quad (66a)
\]
\[
H_{yy}^k := P_{x: x \geq \mu_y I} \left\{ \tilde{H}_{yy}^k \right\} \quad \text{with} \quad \tilde{H}_{yy}^k := (1 - \tau_k) (H_{yy}^{k-1} - h_{yy}^{k-1} (\phi^k)) + h_{yy}^k (\phi^k). \quad (66b)
\]
To analyze the approximation error of $H_{xy}^k$, we decompose it into
\[
\mathbb{E}
\left[
\|H_{xy}^k - H_{xy}(x^k, y^k)\|^2 | \mathcal{F}^k
\right] \leq \mathbb{E}
\left[
\|\hat{H}_{xy}^k - H_{xy}(x^k, y^k)\|^2 | \mathcal{F}^k
\right]
= \mathbb{E}
\left[
\|\hat{H}_{xy}^k - H_{xy}(x^k, y^k)\|^2 | \mathcal{F}^k
\right] + \sum_{i,j} \text{Var}
\left[
(\hat{H}_{xy}^k - H_{xy}(x^k, y^k))_{i,j} | \mathcal{F}^k
\right]
\tag{67}
\]
where the inequality holds since the projection onto the convex set $\{X : X \succeq \mu_g I\}$ is non-expansive, and the equality comes from the bias and variance decomposition that $\text{Var}[X] = \mathbb{E}[X^2] - \mathbb{E}[X]^2$ for any random variable $X$.

We first analyze the bias term in (67) by
\[
\mathbb{E}
\left[
\hat{H}_{xy}^k - H_{xy}(x^k, y^k) | \mathcal{F}^k
\right] = (1 - \tau_k) \left( H_{xy}^{k-1} + h_{xy}^k(\phi^k) - h_{xy}^{k-1}(\phi^k) \right) + \tau_k h_{xy}^k(\phi^k) - H_{xy}(x^k, y^k) | \mathcal{F}^k
\]
\[
= (1 - \tau_k) \left( H_{xy}^{k-1} + H_{xy}(x^k, y^k) - H_{xy}(x^{k-1}, y^{k-1}) \right) + \tau_k H_{xy}(x^k, y^k) - H_{xy}(x^k, y^k)
\]
\[
= (1 - \tau_k) \left( H_{xy}^{k-1} - H_{xy}(x^{k-1}, y^{k-1}) \right). \tag{68}
\]
The variance term in (67) follows
\[
\sum_{i,j} \text{Var}
\left[
(\hat{H}_{xy}^k - H_{xy}(x^k, y^k))_{i,j} | \mathcal{F}^k
\right] = \sum_{i,j} \text{Var}
\left[
(\hat{H}_{xy}^k)_{i,j} | \mathcal{F}^k
\right]
\]
\[
\leq 2(1 - \tau_k)^2 \sum_{i,j} \text{Var}
\left[
(h_{xy}^k(\phi^k) - h_{xy}^{k-1}(\phi^k))_{i,j} | \mathcal{F}^k
\right] + 2\tau_k^2 \sum_{i,j} \text{Var}
\left[
(h_{xy}^k(\phi^k))_{i,j} | \mathcal{F}^k
\right]
\]
\[
\leq 2(1 - \tau_k)^2 \mathbb{E}
\left[
\|h_{xy}^k(\phi^k) - h_{xy}^{k-1}(\phi^k)\|^2 | \mathcal{F}^k
\right] + 2\tau_k^2 \sum_{i,j} \text{Var}
\left[
(h_{xy}^k(\phi^k))_{i,j} | \mathcal{F}^k
\right]
\]
\[
\leq 2(1 - \tau_k)^2 \left( \tilde{L}_{gxy}^2 + \tilde{L}_{gxy}^2 \right) \left( \|x^k - x^{k-1}\|^2 + \|y^k - y^{k-1}\|^2 \right) + 2\tau_k^2 \sigma_{gxy}^2 \tag{69}
\]
where (a) uses $\text{Var}[X] \leq \mathbb{E}[X]^2$ and (b) follows from Assumptions 1 and 3.

Therefore, plugging (68) and (69) into (67), we have
\[
\mathbb{E}
\left[
\|H_{xy}^k - H_{xy}(x^k, y^k)\|^2 | \mathcal{F}^k
\right] \leq (1 - \tau_k)^2 \left\| H_{xy}^{k-1} - H_{xy}(x^{k-1}, y^{k-1}) \right\|^2 + 2\tau_k^2 \sigma_{gxy}^2
\]
\[+ 2(1 - \tau_k)^2 \left( \tilde{L}_{gxy}^2 + \tilde{L}_{gxy}^2 \right) \left( \|x^k - x^{k-1}\|^2 + \|y^k - y^{k-1}\|^2 \right).
\]
Similarly, we can derive the approximation error of $H_{yy}^k$ as
\[
\mathbb{E}
\left[
\|H_{yy}^k - H_{yy}(x^k, y^k)\|^2 | \mathcal{F}^k
\right] \leq (1 - \tau_k)^2 \left\| H_{yy}^{k-1} - H_{yy}(x^{k-1}, y^{k-1}) \right\|^2 + 2\tau_k^2 \sigma_{gxy}^2
\]
\[+ 2(1 - \tau_k)^2 \left( \tilde{L}_{gxy}^2 + \tilde{L}_{gxy}^2 \right) \left( \|x^k - x^{k-1}\|^2 + \|y^k - y^{k-1}\|^2 \right).
\]
The proof is then complete. □
Appendix F. Proof of Theorem 2

Proof: Using Lemmas 4-6, we, respectively, bound the four difference terms in (33) and obtain

\[
\mathbb{E}[\nabla F^{k+1}] - \mathbb{E}[\nabla F^k] \leq -\frac{\alpha_k}{2} \mathbb{E}[\|\nabla F(x^k)\|^2] - \left( \frac{\mu_g L_g}{\mu_g + L_g} \beta_k - \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^2}{\beta_k} - \alpha_k L_f^2 \right) \mathbb{E}[\|y^k - y^*(x^k)\|^2] \\
- \left( \tau_k + \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^2}{\beta_k} - \frac{2 \alpha_k C_g^2}{\mu_g^2} \frac{C_f^2 y_k}{\mu_g^2} \right) \mathbb{E}[\|H_{yy}^k - H_{yy}(x^k, y^k)\|^2] \\
- \left( \tau_k + \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^2}{\beta_k} - \frac{2 \alpha_k C_g^2}{\mu_g^2} \frac{C_f^2 y_k}{\mu_g^2} \right) \mathbb{E}[\|H_{xy}^k - H_{xy}(x^k, y^k)\|^2] \\
+ \frac{L_E}{2} \mathbb{E}[\|x^{k+1} - x^k\|^2] + \left( 1 + \frac{\mu_g L_g}{\mu_g + L_g} \beta_k \right) \beta_k^2 \gamma^2 y_k + \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^4}{\beta_k} + 4 \tau_k^2 \gamma^2 y_k \\
+ 2(1 - \tau_k + \tilde{c}_3 \mathbb{E}[\|x^{k+1} - x^k\|^2] + 2(1 - \tau_k + \tilde{c}_3 \mathbb{E}[\|y^{k+1} - y^k\|^2]. \quad (70)
\]

where the constant is defined as \( \tilde{c}_3 := \frac{L_{2y}}{\mu_g} + \frac{L_{2y}^2}{\mu_g} \).

Note that using the y-update (11b), we also have

\[
\mathbb{E}[\|y^{k+1} - y^k\|^2] = \mathbb{E}[\|\beta_k h^k - (H_{yy}^k)^{-1} H_{xy}^k (x^{k+1} - x^k)\|^2] \\
\leq 2 \beta_k^2 \mathbb{E}[\|h_{yy}^k\|^2] + 2 \mathbb{E}[\|(H_{yy}^k)^{-1}\|^2 \|H_{xy}^k\|^2 \|x^{k+1} - x^k\|^2] \\
\leq 2 \beta_k^2 \mathbb{E}[\|\nabla_y g(x^k, y^k)\|^2] + 2 \beta_k^2 \gamma^2 y_k + 2 \mathbb{E}[\|(H_{yy}^k)^{-1}\|^2 \|H_{xy}^k\|^2 \|x^{k+1} - x^k\|^2] \\
= 2 \beta_k^2 \mathbb{E}[\|\nabla_y g(x^k, y^k)\|^2] + 2 \beta_k^2 \gamma^2 y_k + 2 \left( \frac{C_{g_{xy}}}{\mu_g} \right)^2 \mathbb{E}[\|x^{k+1} - x^k\|^2] \\
\leq 2 \beta_k^2 L_{2y}^2 \mathbb{E}[\|y^k - y^*(x^k)\|^2] + 2 \beta_k^2 \gamma^2 y_k + 2 \left( \frac{C_{g_{xy}}}{\mu_g} \right)^2 \mathbb{E}[\|x^{k+1} - x^k\|^2]. \quad (71)
\]

where (a) follows from \( \mathbb{E}[X^2] = \text{Var}[X] + \mathbb{E}[X]^2 \) and Assumption 3, (b) uses the upper and lower projections of \( H_{xy}^k \) and \( H_{yy}^k \) in (12), and (c) is due to \( \nabla_y g(x^k, y^*(x^k)) = 0 \) as well as Assumption 1.

Selecting parameter \( \tau_k = \frac{1}{\sqrt{K}} \) and using (70)-(71), we have

\[
\mathbb{E}[\nabla F^{k+1}] - \mathbb{E}[\nabla F^k] \leq -\frac{\alpha_k}{2} \mathbb{E}[\|\nabla F(x^k)\|^2] - \left( \frac{\mu_g L_g}{\mu_g + L_g} \beta_k - \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^2}{\beta_k} - \alpha_k L_f^2 \right) \mathbb{E}[\|y^k - y^*(x^k)\|^2] \\
- \left( \frac{1}{\sqrt{K}} - \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^2}{\beta_k} - \frac{2 C_{g_{xy}} C_f y_k}{\mu_g^2} \right) \mathbb{E}[\|H_{yy}^k - H_{yy}(x^k, y^k)\|^2] \\
- \left( \frac{1}{\sqrt{K}} - \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^2}{\beta_k} - \frac{2 C_{g_{xy}} C_f y_k}{\mu_g^2} \right) \mathbb{E}[\|H_{xy}^k - H_{xy}(x^k, y^k)\|^2] \\
+ \left( 1 + \frac{\mu_g L_g}{\mu_g + L_g} \beta_k \right) \beta_k^2 \gamma^2 y_k + \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^4}{\beta_k} + 4 \tau_k^2 \gamma^2 y_k + 8 \beta_k^2 L_{2y}^2 \gamma^2 y_k. \quad (72)
\]
Choosing the stepsize $\alpha_k$ as (27), it will lead to (cf. $c := \tilde{c}_1 \tilde{c}_2$)

\[
\frac{1}{\sqrt{K}} - \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k}{\beta_k} - \frac{2C^2_{g_{xy}} C^2_{f_y} \alpha_k}{\mu_g^2} \geq \frac{1}{\sqrt{K}} + \frac{2C^2_{g_{xy}} C^2_{f_y} \alpha_k}{\mu_g^4} \geq 0 \tag{73a}
\]

\[
\frac{1}{\sqrt{K}} - \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k}{\beta_k} - \frac{2C^2_{f_y} \alpha_k}{\mu_g^2} \geq \frac{1}{\sqrt{K}} - \tilde{c}_1 \tilde{c}_2 \alpha_k - \frac{2C^2_{f_y} \alpha_k}{\mu_g^4} \geq 0 \tag{73b}
\]

where both (a) and (c) follow from $\alpha_k \leq \beta_k$ in (27b); and (b) and (d) follow from the second and the third terms in (27b). In addition, choosing the stepsize $\beta_k$ as (27) will lead to

\[
\frac{\mu_g L_g \beta_k}{\mu_g + L_g} - \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^2}{\beta_k} - \alpha_k L_f^2 - 8\beta_k^2 L_g^2 \geq \frac{\mu_g L_g \beta_k}{\mu_g + L_g} - (\tilde{c}_1 \tilde{c}_2 + L_f^2) \alpha_k - 8\beta_k^2 L_g^2 \geq \frac{\mu_g L_g \beta_k}{2(\mu_g + L_g)} - 8\beta_k^2 L_g^2 \geq \frac{\mu_g L_g \beta_k}{4(\mu_g + L_g)} \tag{73c}
\]

where (e) follows from $\alpha_k \leq \beta_k$ in (27b), (f) is due to the last terms in (27b), and (g) uses (27a).

Using (73) to cancel terms in (72) and using (61) to bound $E[\|x^{k+1} - x^k\|^2]$, we are able to get

\[
E[y^{k+1}] - E[y^k] \leq -\frac{\mu_g L_g \beta_k}{4(\mu_g + L_g)} E[\|y^k - y^*(x^k)\|^2] - \frac{\alpha_k}{2} E[\|\nabla F(x^k)\|^2] + \mathcal{O}\left(\frac{1}{K}\right) \tag{74}
\]

from which we can reach Theorem 2 after telescoping the both sides of (74).

### Appendix G. Proof of Theorem 3

For the strong-convex case, we slightly modify the update of $x^k$ to

\[
x^{k+1} = \mathcal{P}_X \left( x^k - \alpha_k \tilde{h}_f^k \right) \tag{75}
\]

where $\tilde{h}_f^k$ is defined as (43) and $\mathcal{P}_X$ denotes the projection on set $X$.

Slightly different from the Lyapunov function (32), we define the following Lyapunov function

\[
\mathbb{V}^k := \|x^k - x^*\|^2 + \|y^k - y^*(x^k)\|^2 + \|H^k_{yy} - \nabla^2_{yy} g(x^k, y^k)\|^2 + \|H^k_{xy} - \nabla^2_{xy} g(x^k, y^k)\|^2.
\]

**Lemma 8** Suppose Assumptions 1–3 hold and $F(x)$ is $\mu$-strongly convex. Then $x^k$ satisfies

\[
E[\|x^{k+1} - x^*\|^2] \leq (1 - \mu \alpha_k) E[\|x^k - x^*\|^2] + \frac{2L_f^2}{\mu} \alpha_k E[\|y^k - y^*(x^k)\|^2] + \frac{4C^2_{g_{xy}} C^2_{f_y}}{\mu^2 \mu} E[\|H^k_{yy} - H^k_{yy}(x^k, y^k)\|^2] + \frac{4C^2_{g_{xy}} C^2_{f_y}}{\mu^2 \mu} \alpha_k E[\|H^k_{xy} - H^k_{xy}(x^k, y^k)\|^2] \tag{76}
\]

where $L_f, L_F$ are defined in Lemma 7, and $C_{g_{xy}}$ is the projection radius of $H^k_{xy}$ in (12a).
Proof: We start with

\[
\mathbb{E}[\|x^{k+1} - x^*\|^2 | \mathcal{F}^k] \leq \mathbb{E}[\|x^k - \alpha_k \bar{h}_k^\tau - x^*\|^2 | \mathcal{F}^k] \\
= \|x^k - x^*\|^2 - 2\alpha_k \langle x^k - x^*, \nabla F(x^k) \rangle + \alpha_k^2 \mathbb{E}[\|\bar{h}_k^\tau\|^2 | \mathcal{F}^k]
\]

where (a) follows the fact that \( \mathcal{P}_x \) is non-expansive, and (b) follows the optimality condition that \( \langle \nabla F(x^*), x - x^* \rangle \geq 0 \) for any \( x \in \mathcal{X} \).

Using the \( \mu \)-strong convexity of \( F(x) \), it follows that

\[
- \langle x^k - x^*, \nabla F(x^k) - \nabla F(x^*) \rangle \leq -\mu \| x^k - x^* \|^2
\]

plugging which into (77) leads to

\[
\mathbb{E}[\|x^{k+1} - x^*\|^2 | \mathcal{F}^k] \leq (1 - 2\mu \alpha_k) \|x^k - x^*\|^2 + 2\alpha_k \langle x^k - x^*, \nabla F(x^k) - \mathbb{E}[\bar{h}_k^\tau | \mathcal{F}^k] \rangle + \alpha_k^2 \mathbb{E}[\|\bar{h}_k^\tau\|^2 | \mathcal{F}^k]
\]

where (c) uses the Young’s inequality. Plugging (45) into the above completes the proof.

\[
\text{Similar to (33), we first quantify the difference between consecutive Lyapunov functions as}
\]

\[
\mathbb{E}[\|x^{k+1} - x^*\|^2] - \mathbb{E}[\|x^k - x^*\|^2] \leq -\mu \alpha_k \mathbb{E}[\|x^k - x^*\|^2] - \left( \frac{\mu_g \bar{L}_g \beta_k}{\mu_g + \bar{L}_g} - \tilde{c}_3 \frac{\alpha_k^2}{\beta_k} \right) \mathbb{E}[\|y^k - y^*(x^k)\|^2]
\]

where (a) follows the fact that \( \mathcal{P}_x \) is non-expansive, and (b) follows the optimality condition that \( \langle \nabla F(x^*), x - x^* \rangle \geq 0 \) for any \( x \in \mathcal{X} \).

Using the \( \mu \)-strong convexity of \( F(x) \), it follows that

\[
- \langle x^k - x^*, \nabla F(x^k) - \nabla F(x^*) \rangle \leq -\mu \| x^k - x^* \|^2
\]

plugging which into (77) leads to

\[
\mathbb{E}[\|x^{k+1} - x^*\|^2 | \mathcal{F}^k] \leq (1 - 2\mu \alpha_k) \|x^k - x^*\|^2 + 2\alpha_k \langle x^k - x^*, \nabla F(x^k) - \mathbb{E}[\bar{h}_k^\tau | \mathcal{F}^k] \rangle + \alpha_k^2 \mathbb{E}[\|\bar{h}_k^\tau\|^2 | \mathcal{F}^k]
\]

where (c) uses the Young’s inequality. Plugging (45) into the above completes the proof.

\[
\text{Similar to (33), we first quantify the difference between consecutive Lyapunov functions as}
\]

\[
\mathbb{E}[\|x^{k+1} - x^*\|^2] - \mathbb{E}[\|x^k - x^*\|^2] \leq -\mu \alpha_k \mathbb{E}[\|x^k - x^*\|^2] - \left( \frac{\mu_g \bar{L}_g \beta_k}{\mu_g + \bar{L}_g} - \tilde{c}_3 \frac{\alpha_k^2}{\beta_k} \right) \mathbb{E}[\|y^k - y^*(x^k)\|^2]
\]

where (a) follows the fact that \( \mathcal{P}_x \) is non-expansive, and (b) follows the optimality condition that \( \langle \nabla F(x^*), x - x^* \rangle \geq 0 \) for any \( x \in \mathcal{X} \).

Using the \( \mu \)-strong convexity of \( F(x) \), it follows that

\[
- \langle x^k - x^*, \nabla F(x^k) - \nabla F(x^*) \rangle \leq -\mu \| x^k - x^* \|^2
\]

plugging which into (77) leads to

\[
\mathbb{E}[\|x^{k+1} - x^*\|^2 | \mathcal{F}^k] \leq (1 - 2\mu \alpha_k) \|x^k - x^*\|^2 + 2\alpha_k \langle x^k - x^*, \nabla F(x^k) - \mathbb{E}[\bar{h}_k^\tau | \mathcal{F}^k] \rangle + \alpha_k^2 \mathbb{E}[\|\bar{h}_k^\tau\|^2 | \mathcal{F}^k]
\]

where (c) uses the Young’s inequality. Plugging (45) into the above completes the proof.
Note that for the projected update (75), (60) still holds. Plugging (71) and (60) into (80), we have
\[
E[\mathcal{V}^{k+1}] - E[\mathcal{V}^k] \leq -\mu\alpha_k E[\|x^k - x^*\|^2] + \left( 2 + 4\tilde{c}_3 + 8\tilde{c}_3 \left( \frac{C_g}{\mu_g} \right)^2 \left( C_f^2 + \left( \frac{C_g}{\mu_g} \right)^2 C_f^2 \right) \right) \alpha_k^2
\]
\[= \left( \frac{\mu_g L_g \beta_k}{\mu_g + L_g} - \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^2}{\beta_k} \right) - \frac{2\beta_k^2}{\mu \alpha_k} \beta_k^2 - 8\beta_k^2 L^2 L_g^2 \mathbb{E}[\|y^k - y^*(x^k)\|^2]
\]
\[- \left( \frac{\tau_{k+1} - \tilde{c}_1 \tilde{c}_2}{\beta_k} \frac{\alpha_k^2}{\beta_k} \frac{4C_g^2 C_f^2}{\mu^4 \mu} \alpha_k \right) \mathbb{E}[\|H_{yy}^k - H_{yy}(x^k, y^k)\|^2]
\]
\[- \left( \frac{\tau_{k+1} - \tilde{c}_1 \tilde{c}_2}{\beta_k} \frac{\alpha_k^2}{\beta_k} \frac{4C_g^2 C_f^2}{\mu^4 \mu} \alpha_k \right) \mathbb{E}[\|H_{xy}^k - H_{xy}(x^k, y^k)\|^2]
\]
\[+ \left( 1 + \frac{\mu_g L_g}{\mu_g + L_g} \beta_k \right) \frac{4\tilde{c}_4 \sigma_g + \tilde{c}_1 \tilde{c}_2 \alpha_k^2 \frac{1}{\beta_k} \left( \frac{4C_g^2}{\mu^4 \mu} \alpha_k \right)}{4(\mu_g + L_g)} \beta_k^2 \sigma_g + 4\tilde{c}_4 \beta_k^2 \sigma_g + 8\tilde{c}_4 \beta_k^2 \sigma_g + \tilde{c}_6 \beta_k^2 , \tag{81}
\]
We choose the stepsizes \( \alpha_k, \beta_k, \tau_k \) as (30) to guarantee that (cf. \( c := \tilde{c}_1 \tilde{c}_2 \))
\[
\begin{align*}
(a) \quad & \tau_{k+1} - \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^2}{\beta_k} \frac{4C_g^2 C_f^2}{\mu^4 \mu} \alpha_k \geq \frac{\beta_k}{4}; & (b) \quad & \tau_{k+1} - \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^2}{\beta_k} \frac{4C_g^2 C_f^2}{\mu^4 \mu} \alpha_k \geq \frac{\beta_k}{4} \\
(c) \quad & \frac{\mu_g L_g}{\mu_g + L_g} \beta_k - \tilde{c}_1 \tilde{c}_2 \frac{\alpha_k^2}{\beta_k} \frac{2L_f^2}{\mu} \alpha_k - 8\beta_k^2 L^2 L_g^2 \geq \frac{\mu_g L_g}{4(\mu_g + L_g)} \beta_k \tag{82}
\end{align*}
\]
Therefore, plugging (82) into (81), we have
\[
E[\mathcal{V}^{k+1}] - E[\mathcal{V}^k] \leq -\mu\alpha_k E[\|x^k - x^*\|^2] - \frac{\mu_g L_g}{4(\mu_g + L_g)} \beta_k E[\|y^k - y^*(x^k)\|^2]
\]
\[- \frac{\beta_k}{4} E[\|H_{yy}^k - H_{yy}(x^k, y^k)\|^2] - \frac{\beta_k}{4} E[\|H_{xy}^k - H_{xy}(x^k, y^k)\|^2] + \tilde{c}_5 \beta_k^2
\]
\[\leq -\tilde{c}_5 \beta_k E[\mathcal{V}^k] + \tilde{c}_6 \beta_k^2 \tag{83}
\]
where the first and second inequalities hold since we define
\[
\tilde{c}_5 := \min \left\{ \frac{\mu\alpha_k}{\beta_k}, \frac{\mu_g L_g}{4(\mu_g + L_g)}, \frac{1}{4} \right\} = O(1)
\]
\[
\tilde{c}_6 := \left( 1 + \frac{\mu_g L_g}{\mu_g + L_g} \right) \beta_k \sigma_g + \frac{\alpha_k^2}{4\beta_k} \sigma_g + 4\sigma_g + 8\tilde{c}_4 \beta_k^2 \sigma_g + 4 \tilde{c}_5 \beta_k^2 = O(1). \tag{84}
\]
If we choose \( \beta_k = \frac{2}{\tilde{c}_5(K_0 + \tau_k)} \), where \( K_0 \) is a sufficiently large constant, then we have
\[
E[\mathcal{V}^K] \leq \prod_{k=0}^{K-1} \left( 1 - \tilde{c}_5 \beta_k \right) \mathcal{V}^0 + \tilde{c}_6 \sum_{k=0}^{K-1} \beta_k^2 \prod_{j=k+1}^{K-1} \left( 1 - \tilde{c}_5 \beta_j \right)
\]
\[\leq \frac{(K_0 - 2)(K_0 - 1)}{(K_0 + K - 2)(K_0 + K - 1)} \mathcal{V}^0 + \frac{\tilde{c}_6}{\tilde{c}_5} \sum_{k=0}^{K-1} 4 \frac{(k + K_0 - 1)(k + K_0)}{(k + K_0)(K + K_0 - 2)(K + K_0 - 1)}
\]
\[\leq \frac{(K_0 - 1)^2}{(K_0 + K - 1)^2} \mathcal{V}^0 + \frac{4\tilde{c}_6 K}{\tilde{c}_5^2 (K_0 + K - 1)^2} \tag{85}
\]
from which the proof is complete.
