A central limit theorem for stochastic heat equations in random environment

Lu Xu
The University of Tokyo

Abstract In this article, we investigate the asymptotic behavior of the solution to a one-dimensional stochastic heat equation with random nonlinear term generated by a stationary, ergodic random field. We extend the well-known central limit theorem for finite-dimensional diffusions in random environment to this infinite-dimensional setting. Due to our result, a central limit theorem in $L^1$ sense with respect to the randomness of the environment holds under a diffusive time scaling. The limit distribution is a centered Gaussian law whose covariance operator is explicitly described. It concentrates only on the space of constant functions.

Keywords Stochastic heat equation, Random environment, Central limit theorem

1 Introduction and main result

Homogenization of finite-dimensional diffusions in stationary and ergodic environments is a well-studied topic, including periodic and quasiperiodic environments as special cases. In the early works [10] and [16], central limit theorems are established for diffusions driven by random, self-adjoint operators of divergence type. Diffusions without drift are considered in [17]. In [13], an invariance principle in a quenched sense is obtained for diffusions in ergodic, almost surely $C^2$-smooth environment, through a study on the fundamental solutions corresponding to its generator.

A good review of finite-dimensional results can be found in [9] Sect. 9], where the main approach is to record the environment viewed from the particle as a Markov process. Every sample path of the diffusion is decomposed into the sum of an additive functional of the environment process and a martingale with stationary and ergodic increments. The general method to prove a central limit theorem for additive functional of Markov process is firstly developed in [8] for reversible case and be extended later in [14], [15] and [19] to non-reversible case.
where a sector condition holds. We rely on these results in this article, but in an infinite-dimensional setting.

Our aim is to extend this strategy to an infinite-dimensional, nonlinear system. We study the homogenization of the solution to a stochastic partial differential equation in random environment. The equation considered here is a stochastic heat equation on the unit interval $[0, 1]$ driven by standard space–time white noise and having a random nonlinear term. Different from the finite-dimensional model, the law of the nonlinear term is supposed to be stationary and ergodic under only constant shifts, that is, a group of transformations indexed by $\mathbb{R}$. We adopt this setting since the Laplacian in the equation is preserved only by these transformations, which is necessary for obtaining the Markov property of the environment process.

The nonlinear term is supposed to be the composition of a gradient-type part and a divergence-free part. If only deterministic gradient-type environment is adopted, this equation is used to describe the motion of a flexible Brownian string in some potential field, see [5]. Moreover, if the environment degenerates to a periodic nonlinear term, the model is closely related to the dynamical sine-Gordon equation (see, e.g., [7]), and an invariance principle is obtained in [20]. The divergence-free part can be added since it preserves the equilibrium state.

For homogenization of finite-dimensional diffusions in divergence-free random field, we refer to [12].

To state our model, we first introduce some basic notations. Throughout this article let $H = L^2[0, 1]$. The inner product and the norm on $H$ are denoted by $\langle \cdot, \cdot \rangle_H$ and $\| \cdot \|_H$. Let $E$ be the Banach space $C[0, 1]$ equipped with the uniform topology. Denote by $E_0$ the subspace of $E$ consisting of functions which vanish at 0. Denote by $\mu_0$ the Wiener measure on $E_0$ induced by a standard Brownian motion. Since the sample path of a Brownian motion is almost surely Hölder continuous with order less than $\frac{1}{2}$, we fix some $\alpha \in (0, \frac{1}{2})$ and introduce $E^\alpha$ as the space of $\alpha$-Hölder continuous functions on $[0, 1]$. $E, E^\alpha$ and $E_0$ are treated as subspaces of $H$.

Recall that a real-valued function $f$ defined on $H$ is said to be Fréchet differentiable, if at every $h \in H$ there exists some $Df(h) \in H$ such that

$$\lim_{h' \in H: \|h'\|_H \downarrow 0} \frac{f(h + h') - f(h) - (Df(h), h')_H}{\|h'\|_H} = 0.$$  

$Df$ is called the Fréchet derivative of $f$. Higher-order derivatives are defined inductively. For a positive integer $k$, by $C^k_b(H)$ we denote the class of all bounded functions on $H$ which have bounded and continuous Fréchet derivatives up to the $k$-th order.

Now we state our model precisely. Suppose that $(\Sigma, \mathcal{A}, \mathbb{Q})$ and $(\Omega, \mathcal{F}, \mathbb{P})$ are two complete probability spaces, the latter of which is equipped with a filtration of $\sigma$-fields $\{\mathcal{F}_t \subseteq \mathcal{F}; t \geq 0\}$ satisfying the usual conditions. Let $W(t, x)$ be a standard cylindrical Brownian motion defined on $(\Omega, \mathcal{F}, \mathbb{P})$ and adapted to $\mathcal{F}_t$, and

$$\{(V(\sigma, u), B(\sigma, u)) \in \mathbb{R} \times H; (\sigma, u) \in \Sigma \times H\}$$
be an $\mathbb{R} \times H$-valued random field over $H$ on $(\Sigma, \mathcal{A}, \mathbb{Q})$. Suppose that $V$ is Fréchet differentiable in $u$ for almost all $\sigma$, and let $U$ be the $H$-valued random field defined by $U = DV + B$. For fixed $\sigma \in \Sigma$, consider a one-dimensional stochastic heat equation with homogeneous Neumann boundary conditions and initial condition $v \in E$.

\[
\begin{aligned}
&\partial_t u(t, x) = \frac{1}{2} \partial_x^2 u(t, x) - U(\sigma, u(t)) + \dot{W}(t, x), \quad t > 0, \ x \in (0, 1); \\
&\partial_x u(t, x)|_{x=0} = \partial_x u(t, x)|_{x=1} = 0, \quad t > 0; \\
u(0, x) = v(x), \quad &x \in [0, 1].
\end{aligned}
\]

Equation (1.1) is called a stochastic heat equation in random environment $U$, and every $\sigma \in \Sigma$ is called a fixed environment. To make sure that for fixed $\sigma$, (1.1) has a strong solution in the space of continuous functions, assume that

(A1) \ $U(\sigma, \cdot) = DV(\sigma, \cdot) + B(\sigma, \cdot)$ is a bounded and Lipschitz continuous map from $H$ to $H$ for $\mathbb{Q}$-almost all $\sigma \in \Sigma$.

Under (A1), for almost all $\sigma$, the unique solution $u^{\sigma, v}(t, x)$ to (1.1) is continuous in $t$ and $\alpha$-Hölder continuous in $x$ (see [5 6]) for $\alpha < \frac{1}{2}$. Therefore, $\{u^{\sigma, v}(t); t \geq 0\}$ forms a continuous Markov process taking values in $E^\alpha$. Consider the stochastic process on the product space $(\Sigma \times \Omega, \mathcal{A} \otimes \mathcal{F})$ defined as

\[
u^v(t) \triangleq u^{\sigma, v}(t), \quad t \geq 0.
\]

It is called the solution to (1.1) in random environment, which is the main object we want to study in this article. Sometimes we omit the initial condition $v$ and write it as $u(t)$ for short. To simplify the discussion on the generator of the environment process defined in Definition 2.2 later, also assume that

(A2) $\sup_{\Sigma \times H} \{\|V\| + \|DV\|_H + \|B\|_H\} < \infty$.

To continue, we discuss the path space and the distribution of $\{V, B\}$. Let

\[
C^{1, 0}(H; \mathbb{R} \times H) \triangleq \left\{ \phi = (v, b) : H \to \mathbb{R} \times H \mid v \in C^1(H; \mathbb{R}), b \in C(H; H) \right\}.
\]

Due to the regularity of $u^{\sigma, v}(t, \cdot)$, the distribution of $u^{\sigma, v}(t)$ depends only on the law of the subfield $\{V, B\} \triangleq \{V(u), B(u)\}_{u \in E^\alpha}$. Hence, let

\[
\Sigma^0_{\text{path}} \triangleq \left\{ \tilde{\phi} : E^\alpha \to \mathbb{R} \times H \mid \exists \phi \in C^{1, 0}(H; \mathbb{R} \times H), \text{s.t.} \tilde{\phi} = \phi|_{E^\alpha} \right\}.
\]

Denote by $\Sigma_{\text{path}}$ the completion of $\Sigma^0_{\text{path}}$ under the Fréchet metric

\[
d_{\Sigma}(\sigma_1, \sigma_2) = \sum_{k=1}^{\infty} \frac{1}{2^k} \frac{d_{\Sigma, k}(\sigma_1, \sigma_2)}{1 + d_{\Sigma, k}(\sigma_1, \sigma_2)}, \quad (1.2)
\]

where for $\sigma_1 = (\tilde{v}_1, \tilde{b}_1)$ and $\sigma_2 = (\tilde{v}_2, \tilde{b}_2) \in \Sigma$,

\[
d_{\Sigma, k}(\sigma_1, \sigma_2) = \sup_{u \in E^\alpha_k} \left\{ \|\tilde{v}_1(u) - \tilde{v}_2(u)\| + \|D\tilde{v}_1(u) - D\tilde{v}_2(u)\|_H + \|\tilde{b}_1(u) - \tilde{b}_2(u)\|_H \right\},
\]
function concentrates on the space of constant functions, i.e., for any bounded continuous rem in \(L^1\), equip it with the Borel \(\tau_1\) where \(c\) holds for all \(f\) is ergodic if for measurable set \(p\)\(\delta\) stands for the constant function \(1\) such that \(\delta = \tilde{\delta}(\cdot + c1)\), \(\forall c \in \mathbb{R}\)\(\delta\) is ergodic if for measurable set \(A \subseteq \Sigma_{path}\) such that \(p(A \Delta \tau_c[A]) = 0\) for all \(c \in \mathbb{R}\), we have either \(p(A) = 1\) or \(p(A) = 0\), where \(\Delta\) stands for the symmetric difference. Let \(P_{\tilde{V}, \tilde{B}}\) be the distribution of \(\{\tilde{V}, \tilde{B}\}\) on \(\Sigma_{path}\) and assume that

(A3) \(P_{\tilde{V}, \tilde{B}}\) is stationary and ergodic under \(\{\tau_c; c \in \mathbb{R}\}\), and

\[P_{\tilde{V}, \tilde{B}}(\tau_c \tilde{\phi} = \tilde{\phi}, \forall c \in \mathbb{R}) < 1.\]  

The translation invariance and ergodicity of the environment are usually necessary for studying homogenization in such a model. Since \(\{\tilde{\phi} \mid \tau_c \tilde{\phi} = \tilde{\phi}, \forall c \in \mathbb{R}\}\) is obviously a translation invariant set, \(\tilde{\phi}\) is periodic in the sense \(U(\sigma, u)\) is periodic in the sense \(U(\sigma, u) = U(\sigma, u + c1)\). For a stochastic heat equation with local, periodic and gradient-type nonlinear term, an invariance principle is obtained in \(\cite{20}\). Finally, we assume that

(A4) \(\exists\) a measurable set \(\Sigma_1\) such that \(\tau_c[\Sigma_1] = \Sigma_1\), \(\mathbb{Q}(\Sigma_1) = 1\) and for all \(\sigma \in \Sigma_1\),

\[
\int_{E_0} e^{-2V(\sigma, u)} \langle Df(u), B(\sigma, u) \rangle_H \mu_0(du) = 0
\]

holds for all \(f\) on \(H\) such that \(f(u) = f^1(\langle u, \varphi_1 \rangle_H, \ldots, \langle u, \varphi_M \rangle_H)\) for some \(M \geq 1, f^1 \in C_0^1(\mathbb{R}^M)\) and \(\varphi_1, \ldots, \varphi_M \in H\).

(A4) is equivalent to say that \(\delta(e^{-2V} B) = 0\) holds for all \(\sigma \in \Sigma_1\), where \(\delta\) is the divergence operator adjoint to the Malliavin derivative (see, e.g., \(\cite{11}\) p. 35, Definition 1.3.1). One can see in Lemma 2.5 and Proposition 2.6 that a non-gradient field satisfying (A4) preserves the equilibrium state in both fixed and random environment. Our main result, a central limit theorem for \(u^n(t)\), is stated as follows.

**Theorem 1.1.** Under (A1) to (A4), \(u(t)/\sqrt{t}\) satisfies the central limit theorem in \(L^1\) sense with respect to the environment and the limit distribution concentrates on the space of constant functions, i.e., for any bounded continuous function \(f\) on \(E\),

\[
\lim_{t \to \infty} E_\mathbb{Q}\left| E_\mathbb{P}\left[ f\left(\frac{u(t)}{\sqrt{t}}\right) \right] - \int_R f(y) \Phi_\sigma(y) dy \right| = 0,
\]

(1.6)
where \( y_1 \) is the function on \([0, 1]\) taking constant value \( y \in \mathbb{R} \), and \( \Phi_a \) is the probability density function of a 1-d centered Gaussian law with variance \( a^2 \) defined in (3.17) below. Furthermore there exists some strictly positive constant \( C \) depending only on \( V \) such that \( C \leq a^2 \leq 1 \).

Remark 1.2. A question naturally rises up is whether central limit theorem holds \( \mathbb{Q} \)-almost surely. We would like to point out here, that such quenched result usually relies on dimensions (cf. \([1]\)). The most challenging part in proving a quenched result is to show the sublinearity of the corrector, which usually involves methods like heat kernel estimates or Sobolev inequality. Since these methods are not expectable in our setting, the quenched version of Theorem 1.1 cannot be achieved easily.

In Sect. 2, we introduce the evolution of the environment seen from the solution, which is recorded as an ergodic Markov process with values in a new space consisting of series of environments. In Sect. 3, we prove Theorem 1.1 mainly based on a sector condition and some general arguments in \([9, \text{Sects. 2, 9}]\). Before these contents, we close this section with two examples, showing that both periodic and quasiperiodic nonlinear terms are included in our model as special cases.

Example 1.3. Take \( \Sigma = [0, 1] \), \( \mathcal{A} = \mathcal{B}(\Sigma) \) and \( \mathbb{Q} \) to be the Lebesgue measure. Suppose \( V \) to be a measurable function on \([0, 1] \times \mathbb{R} \) such that

\[
V(x, \cdot) \in C^1(\mathbb{R}), \quad V(x, y) = V(x, y + 1), \quad \forall x \in [0, 1], \quad y \in \mathbb{R}.
\]

Define the random field \((V, B)\) for all \( \sigma \in \Sigma \) and \( u \in E \) as

\[
V(\sigma, u) = \int_0^1 V(x, u(x) + \sigma)dx
\]

and \( B(\sigma, u) \equiv 0 \). Assume that both \( V \) and \( \frac{\partial}{\partial y} V \) are uniformly bounded, then (A1) to (A4) are fulfilled. Denote by \( u^{\sigma, \cdot} \) the solution to (1.1), then \( u^{\sigma, \cdot - \sigma}(t, x) + \sigma \) solves the stochastic heat equation with the periodic nonlinear term \( \frac{\partial}{\partial y} V(x, u(t, x)) \).

Example 1.4. For \( d \geq 2 \) take \( \Sigma = [0, 1]^d \), \( \mathcal{A} = \mathcal{B}(\Sigma) \) and \( \mathbb{Q} \) to be the Lebesgue measure. Suppose \( V \) to be a measurable function on \([0, 1] \times \mathbb{R}^d \) such that

\[
V(x, \cdot) \in C^1(\mathbb{R}^d), \quad \forall x \in [0, 1];
\]

\[
V(x, \vec{y}) = V(x, \vec{y} + \vec{e}_i), \quad \forall x \in [0, 1], \quad \forall \vec{y} \in \mathbb{R}^d, \quad \forall i = 1, \ldots, d;
\]

\[
\sup_{[0,1] \times \mathbb{R}^d} \{|V|, |\partial_{y_1} V|, \ldots, |\partial_{y_d} V|\} < \infty,
\]

where \( \vec{e}_i \) is the unit vector in \( \mathbb{R}^d \) of \( i \)-th coordinate. Let \( (\lambda_1, \ldots, \lambda_d) \in \mathbb{R}^d \) be a vector with rationally independent coordinates. Define the random field \((V, B)\) for all \( \sigma \in \Sigma \) and \( u \in E \) as

\[
V(\sigma, u) = \int_0^1 V(x, \lambda_1 u(x) + \sigma_1, \ldots, \lambda_d u(x) + \sigma_d)dx
\]

and \( B(\sigma, u) \equiv 0 \) for all \( \sigma \in \Sigma \) and \( u \in E \). It gives the quasiperiodic model.
Hence, the image of \( v \) is continuous on \([0, \infty)\). Calculation shows that property of \( \{ \ker(\Sigma \times \mathcal{E}) \} \) on \( \Sigma \) such that \( \mathcal{Q} \) is stationary, ergodic and satisfies that

\[
\mathcal{Q}(\Sigma_0) = 0,
\]

(2.1)

where \( \Sigma_0 \triangleq \{ \sigma \in \Sigma \mid \tau_\sigma = \sigma, \forall c \in \mathbb{R} \} \) is a subset of \( \Sigma \).

This section is devoted to the construction of the environment process associated to (1.1). To apply the strategy in [9, Sect. 9], the environment process needs to be a Markov process taking values in a Polish metric space, having a stationary and ergodic probability measure. Given an environment \( \sigma \in \Sigma \) and some \( v \in E \), to shift \( \sigma \) with \( v \) it is natural to consider a map \( \xi : [0, 1] \to \Sigma \) such that

\[
(\xi(x) = \tau_{v(x)}|\sigma, \forall x \in [0, 1].
\]

In the above expression, since \( \xi(\cdot) = \tau_{v(\cdot) - v(0)}|\xi(0) \) where \( v(\cdot) - v(0) \in E_0 = \{ u \in E ; u(0) = 0 \} \), \( \xi \) belongs to the set \( \Xi \) defined as follows:

\[
\Xi \triangleq \{ \xi : [0, 1] \to \Sigma \mid \exists (\sigma, v) \in \Sigma \times E_0 \text{ s.t. } \xi(\cdot) = \tau_{v(\cdot)}|\sigma \}.
\]

(2.2)

Every \( \xi \in \Xi \) is called a series of environments, which describes the environments seen from a function. To construct a metric on \( \Xi \), we need the following lemma.

**Lemma 2.1.** For each \( \xi \) such that \( \xi(0) \notin \Sigma_0 \) in (2.1), there is only one pair of \( \sigma \in \Sigma \) and \( v \in E_0 \) satisfying that \( \xi(\cdot) = \tau_{v(\cdot)}|\sigma \).

**Proof.** For \( \sigma \in \Sigma \), define \( \ker(\sigma) \triangleq \{ c \in \mathbb{R} \mid \tau_c|\sigma = \sigma \} \), then \( \Sigma_0 = \{ \sigma \in \Sigma \mid \ker(\sigma) = \mathbb{R} \} \). Define a subset \( \Xi_0 \subseteq \Xi \) to be

\[
\Xi_0 = \{ \xi \in \Xi \mid \xi(0) \in \Sigma_0 \}.
\]

(2.3)

For \( \xi \notin \Xi_0 \), suppose that \( \xi = \tau_{v(x)}|\sigma = \tau_{v'(x)}|\sigma' \) for some \( (\sigma, v) \) and \( (\sigma', v') \in \Sigma \times E_0 \). Since \( v(0) = v'(0) = 0 \), it is obvious that \( \sigma = \sigma' = \xi(0) \). Notice that \( \ker(\sigma) \) does not contain any non-degenerate interval \([a, b] \), otherwise the group property of \( \{ \tau_c \} \) would imply that \( \ker(\sigma) = \mathbb{R} \) and then \( \xi \notin \Xi_0 \). However, simple calculation shows that

\[
\tau_{v(\cdot) - v'(\cdot)}|\sigma, \forall x \in [0, 1].
\]

Hence, the image of \( v - v' \) contains no non-degenerate interval. As \( v - v' \) is continuous on \([0, 1]\) and \( v(0) - v'(0) = 0 \), this yields that \( v = v' \).

In view of Lemma 2.1, one is able to define a one-to-one map \( \xi \mapsto (\sigma_\xi, v_\xi) \) from \( \Xi \) to \( \Sigma \times E_0 \) such that \( \xi(\cdot) = \tau_{v_\xi(\cdot)}|\sigma_\xi \). Indeed \( \sigma_\xi = \xi(0) \), and when \( \xi \notin \Xi_0 \),
$v_\xi$ is uniquely determined due to Lemma 2.1. For those $\xi \in \Xi_0$, we can simply take $v_\xi(x) \equiv 0$. Equip $\Xi$ with the metric $d_\Xi$ defined as

$$d_\Xi(\xi, \eta) = d_\Sigma(\xi(0), \eta(0)) + \sup_{x \in [0,1]} |v_\xi(x) - v_\eta(x)|, \ \forall \xi, \eta \in \Xi,$$

(2.4) where $d_\Sigma(\cdot, \cdot)$ is the Fréchet metric in (1.2). Observing that $(\Xi, d_\Xi)$ may not be complete, we take the completion and still denote it by $\Xi$. Since both $(E_0, \cdot_{\sup})$ and $(\Sigma, d_\Sigma)$ are Polish spaces, also is $(\Xi, d_\Xi)$. Equip $\Xi$ with the Borel $\sigma$-algebra $\mathcal{G}$, then $\xi \mapsto (\xi(0), v_\xi)$ becomes a measurable map with respect to $\mathcal{A} \otimes \mathcal{B}(E_0)$. Now the environment process can be defined as follows.

**Definition 2.2.** The environment process associated with $(1.1)$ is defined as

$$\xi_t = \xi_t(\cdot) \in \Xi, \ \text{s.t.} \ \xi_t(x) = \tau_{[u^\sigma,v(t,x)]}\sigma, \ \forall x \in [0,1].$$

Recall that $(\Omega, \mathcal{F}, \mathbb{P})$ is the probability space where the noise $\hat{W}(t,x)$ in $(1.1)$ is defined. $\{\xi_t\}_{t \geq 0}$ defined in Definition 2.2 forms a $\Xi$-valued stochastic process on the product space $(\Sigma \times \Omega, \mathcal{A} \otimes \mathcal{F})$. To express the nonlinear term in $(1.1)$ by $\xi_t$, we introduce the derivative operator on $\Xi$. For $f : \Xi \to \mathbb{R}$, let $f^\sigma$ be the function defined as $f^\sigma(v) = f(\tau_{[v(t)]}\sigma)$ for all $v \in E$.

**Definition 2.3.** A function $f$ on $\Xi$ is called differentiable, if for every $\sigma$, $f^\sigma$ can be extended to a Fréchet differentiable function $f^\sigma$ on $H$, and its derivative is defined as $Df(\xi) = Df^\sigma(v)$ for $\xi = \tau_{[v(t)]}\sigma$. Higher-order derivatives are defined inductively. In particular, for differentiable $f$, $Df(\xi) = Df(\xi, \cdot) \in H$ and for twice differentiable $f$, $D^2f(\xi)$ is a bounded bilinear functional on $H \times H$.

The nonlinear term $DV(\sigma, u^{\sigma,v}(t)) + B(\sigma, u^{\sigma,v}(t))$ can be replaced by a function of $\xi_t$. Indeed, recall that every $\sigma = (u, b) \in \Sigma = \Sigma_{\text{path}}$ can be continuously extended to an element in $C^{1,0}(H; \mathbb{R} \times H)$, we can define

$$(V(\xi), B(\xi)) = [\xi(0)] (v_\xi) \in \mathbb{R} \times H, \ \forall \xi \in \Xi,$$

where $v_\xi \in E_0$ is defined by the one-to-one map from $\Xi$ to $\Sigma \times E_0$ mentioned above. By Definition 2.3 and the definition of $\Sigma_{\text{path}}$, it is not hard to see that

$$DV(\xi_t) + B(\xi_t) \overset{d}{=} DV(\sigma, u^{\sigma,v}(t)) + B(\sigma, u^{\sigma,v}(t)) = U(\sigma, u^{\sigma,v}(t)).$$

In summary, without loss of generality we can assume the following framework. Suppose $(\Xi, d_\Xi)$ to be some Polish metric space equipped with the Borel $\sigma$-field $\mathcal{A}$ and some Borel probability measure $\mathbb{Q}$. A group of measurable transformations $\{\tau_c ; c \in \mathbb{R}\}$ is defined on $\Sigma$ such that $\mathbb{Q}$ is stationary, ergodic and satisfies (2.1). Define $\Xi$ as in (2.2) and equip it with the metric $d_\Xi$ in (2.4) and the Borel $\sigma$-algebra $\mathcal{G}$. It suffices to prove Theorem 1.1 for the following equation instead of (1.1):

$$\begin{cases}
\partial_t u^{\sigma,v}(t,x) = \frac{1}{2} \partial^2_x u^{\sigma,v}(t,x) - DV(\xi_t) - B(\xi_t) + \hat{W}(t,x), & t > 0, x \in (0,1); \\
\partial_x u^{\sigma,v}(t,x)|_{x=0} = \partial_x u^{\sigma,v}(t,x)|_{x=1} = 0, & t > 0; \\
u^{\sigma,v}(0,x) = v(x), & x \in [0,1],
\end{cases}$$

\[1.11\]
Applying (2.6) with $\Xi$ with values in $E$ on $\alpha$. With these notations, we have the next proposition.

Using the Markov property of $B$ where $f$ is the function on $E$, the discussion below Lemma 2.1 yields that $v = v(\cdot) - v(0)$, thus by taking $c = v(0)$ in the equation above, we obtain that

$$P^\sigma(t; v, \cdot) = P^\sigma(t; v - c, \cdot - c), \quad \forall c \in \mathbb{R}.$$  

Since $E$ is a random variable on $(\Xi, \mathcal{F})$ taking values in $\mathbb{R} \times H$. The random field generated by $(V(\sigma, u), B(\sigma, u)) = (V(\tau_{\sigma(\cdot)}), B(\tau_{\sigma(\cdot)}))$ is supposed to satisfy $(A1)$, $(A2)$ and $(A4)$ in Sect. 1.

Before stating the Markov property of $\xi_t$, we prepare some notations. Let $B_t(\xi_0)$ be the collections of all bounded measurable functions on $E$ and $\Xi$, respectively. For fixed $\sigma$, $u^{s,v}(t)$ defines a continuous Markov process with values in $E^\alpha \subseteq E$. Denote by $P^\sigma_t$ the associated Markov semigroup defined on $B_t(\Xi)$. Denote by $P^\sigma_{t,v}$ the law of $u^{s,v}$ for fixed $\sigma$ and $v$, and by $E^\sigma_{t,v}$ the corresponding expectation. With these notations, we have the next proposition.

**Proposition 2.4.** The environment process $\{\xi_t, t \geq 0\}$ is a Markov process on $\Xi$. Let $\{P_t, t \geq 0\}$ be the Markov semigroup on $B_0(\Xi)$ determined by $\xi_t$, then

$$P_t f(\xi) = P_t^\xi(0)f(\xi(0)), \quad \forall f \in B_0(\Xi),$$  

where $f^\sigma$ is the function on $E$ defined by $f^\sigma(v) = f(\tau_{\sigma(\cdot)}v)$.

**Proof.** First notice that if $\xi_0 \in \Xi_0$ in (2.3) then the environment $\sigma \in \Sigma_0$. This furthermore implies that $\xi_t = \xi_0$ for all $t \geq 0$ and $f^{\xi(0)}$ is a constant function on $E$. Hence, the Markov property and (2.5) hold obviously in this case.

Pick $\sigma \notin \Sigma_0, v \in E$ and let $\xi = \tau_{\sigma(\cdot)}$. Let $P^\sigma(t; v, \cdot)$ be the transition probability of the solution $u^{\sigma,v}(t, \cdot)$ in a fixed environment. Since $u^{\sigma,v} = u^{\sigma,v+c}$,

$$P^\sigma(t; v, \cdot) = P^\sigma(t; v - c, \cdot - c), \quad \forall c \in \mathbb{R}.$$  

Since $\xi \notin \Xi_0$, the discussion below Lemma 2.1 yields that $v_\xi = v(\cdot) - v(0)$, thus by taking $c = v(0)$ in the equation above, we obtain that

$$P^\sigma(t; v, \cdot) = P^\xi(0)(t; v_\xi, \cdot - v(0)).$$  

Pick some $t > 0$, $h > 0$, $n \geq 0$, $0 \leq t_1 \leq \ldots \leq t_n < t + h$ and bounded measurable functions $f_1, \ldots, f_n, g$ on $\Xi$ arbitrarily. We have

$$E^\sigma_v \left[ \prod_{j=1}^n f_j(\xi_{t_j})g(\xi_{t+h}) \right] = E^\sigma_v \left[ \prod_{j=1}^n f_j^\sigma(u^{\sigma,v}(t_j))g^\sigma(u^{\sigma,v}(t+h)) \right].$$  

Using the Markov property of $u^{\sigma,v}(t)$ for fixed $\sigma$, the expectation above equals to

$$E^\sigma_v \left[ \prod_{j=1}^n f_j^\sigma(u^{\sigma,v}(t_j)) \int_E g^\sigma(u)P^\sigma(h; u^{\sigma,v}(t), du) \right].$$  

Applying (2.6) with $\xi = \xi_t$ and $v = u^{\sigma,v}(t)$, this expectation equals to

$$E^\sigma_v \left[ \prod_{j=1}^n f_j(\xi_{t_j}) \int_E g^\xi(0)(h; v_{\xi_t}, d(u - u^{\sigma,v}(t, 0))) \right] = E^\sigma_v \left[ \prod_{j=1}^n f_j(\xi_{t_j}) \int_E g^\xi(0)(h; v_{\xi_t}, du) \right].$$  

8
Therefore, $\xi_t$ is a Markov process and
\[ \mathcal{P}_t f(\xi) \triangleq \int_E f^{\xi(0)}(u)\mathcal{P}_t^{\xi(0)}(t; v, du) = \mathcal{P}_t^{\xi(0)} f^{\xi(0)}(v), \quad \forall t \geq 0 \]
is the associated Markov semigroup.

Next we construct the stationary and ergodic measure of $\{\mathcal{P}_t, t \geq 0\}$. Before discussing the environment process, we give a lemma concerning the (infinite) stationary measure in frozen environment $\sigma \in \Sigma$. Notice that in [5, Sect. 4], the same problem is discussed for the case that $B(\sigma, \cdot) = 0$ and $V(\sigma, \cdot)$ is local.

**Lemma 2.5.** For almost all $\sigma \in \Sigma, \{\mathcal{P}_t^\sigma, t \geq 0\}$ admits a stationary measure
\[ \pi^\sigma(dv) = \exp(-2V(\sigma,v))\mu(dv), \]
where $(E, \mu)$ is the infinite measure determined by a stochastic process $\{w(x); x \in [0,1]\}$ satisfying that $w(\cdot) - w(0)$ is a one-dimensional Brownian motion, while $w(0)$ subjects to the Lebesgue measure on $\mathbb{R}$. Moreover if $B \equiv 0$, then $\pi^\sigma$ is reversible.

This lemma follows from a Galerkin approach. For $k \geq 1$, let $\lambda_k = 2(k - 1)^2\pi^2$ be the eigenvalues of $-\frac{1}{2}\partial^2_x$ on $H$ with Neumann boundary condition. The corresponding eigenvectors are $h_1 = 1$ and $h_k(x) = \sqrt{2}\cos[2(k - 1)\pi x]$ for $x \in [0,1]$ and $k \geq 2$. With these notations, we sketch the proof for completeness.

**Proof of Lemma 2.5.** In view of (A4), since $(V,B)(\sigma, v + c1) = (V,B)(\tau, \sigma, v)$ holds for all $c \in \mathbb{R}$, it is easy to see that if $\sigma$ belongs to $\Sigma_1$, \begin{equation} E_{\pi^\sigma}[(Df, B(\sigma, \cdot))_H] = \int_{\mathbb{R}} E_{\mu_0} \left[ e^{-2V(\tau, \sigma, \cdot)} (Df, B(\tau, \sigma, \cdot)) \right] dc = 0, \tag{2.7} \end{equation}
for $f(v) = f^\dagger(\langle v, h_1 \rangle_H, \ldots, \langle v, h_N \rangle_H)$ with $f^\dagger \in C^1_b(\mathbb{R}^N)$. Since here only fixed environment is considered, we temporarily omit $\sigma$ and write $V, B, w^\dagger(t)$ in short of $V(\sigma, \cdot), B(\sigma, \cdot)$ and $u^\sigma(t)$. Let $\nu(dv) = e^{-2V(v)}\mu(dv)$, and we prove that $\nu(dv)$ is stationary for $\{u^\sigma(t); t \geq 0\}$ under (2.7).

First assume that $V$ and $B$ are finite-dimensional dependent. Precisely, for some $N \geq 1$, $V^\dagger \in C^1_b(\mathbb{R}^N)$ and $B^\dagger = (B^\dagger_1, \ldots, B^\dagger_N) \in C^1_b(\mathbb{R}^N; \mathbb{R}^N)$, we have
\[ V(v) = V^\dagger(\langle v, h_1 \rangle_H, \ldots, \langle v, h_N \rangle_H), \quad B(v) = \sum_{k=1}^N B^\dagger_k(\langle v, h_1 \rangle_H, \ldots, \langle v, h_N \rangle_H)h_k. \tag{2.8} \]
Let $X^k_t = \langle u^\sigma(t), h_k \rangle_H$, then $X_t = (X^1_t, \ldots, X^N_t) \in \mathbb{R}^N$ solves
\[ dX^k_t = -\lambda_k X^k_t dt - \int_{\mathbb{R}^N} \Psi^k(x) dx - B^\dagger_k(X_t) dt + d(W(t, \cdot), h_k)_H, \quad X^k_0 = \langle v, h_k \rangle_H. \]
Define $\Psi_k(x) = \sqrt{\lambda_k}e^{-\lambda_k x^2}$ for $k \geq 1$ and $x \in \mathbb{R}$ and observe that the marginal distribution of $\mu$ on $(\langle v, h_1 \rangle_H, \ldots, \langle v, h_N \rangle_H)$ is $(\mathbb{R}^N, \prod_{k=1}^N \Psi_k(x_k) dx_k)$. 

9
By (2.7),

$$
\int_{\mathbb{R}^N} e^{-2V^1(x)} \left[ B^1(x) \cdot \nabla f(x) \right] \prod_{k=1}^{N} \Psi_k(x_k) dx_k = 0, \quad \forall f \in C^1_c(\mathbb{R}^N). \tag{2.9}
$$

Hence \(e^{-2V^1(x)} \prod_{k=1}^{N} \Psi_k(x_k) dx_k\) is an (infinite) invariant measure for \(X_t\). Noting that now \(\{X^t_k, M > N\}\) forms a mutually independent system of Ornstein–Uhlenbeck processes which is independent of \(X_t\), we can conclude that \(\nu(dv) = e^{-2V(v)} \mu(dv)\) is a stationary measure for \(\{u^v(t); t \geq 0\}\).

For general \(V\) and \(B\), we consider their marginal expectations. Precisely speaking, for \(N \geq 1\) and \(x = (x_1, \ldots, x_N) \in \mathbb{R}^N\) define

$$
V^1_N(x) = \prod_{l=N+1}^{\infty} \left[ \int_{\mathbb{R}} \Psi_l(y_l) dy_l \right] V \left( \sum_{l=1}^{N} x_l h_l + \sum_{l=N+1}^{\infty} y_l h_l \right).
$$

Similarly, write \(U_k = e^{-2V}(B, h_k)_H\) and for \(k = 1, \ldots, N\) define

$$
B^\dagger_{N,k}(x) = e^{2V^1_N(x)} \prod_{l=N+1}^{\infty} \left[ \int_{\mathbb{R}} \Psi_k(y_l) dy_l \right] U_k \left( \sum_{l=1}^{N} x_l h_l + \sum_{l=N+1}^{\infty} y_l h_l \right).
$$

Define \(V_N\) and \(B_N\) by substituting \(V^1_N, B^\dagger_N\) for \(V^1, B^\dagger\) in (2.8), and let \(u^v_N(t)\) be the solution to (1.1) with \(DV + B\) replaced by \(DV_N + B_N\). From the Lipschitz continuity of \(V\), \(DV\) and \(B\), we get for every fixed \(v \in H\) that

$$
\lim_{N \to \infty} |V_N(v) - V(v)| + \|DV_N(v) - DV(v)\|_H + \|B_N(v) - B(v)\|_H = 0.
$$

Since \(V, DV\) and \(B\) are uniformly bounded, we can obtain that

$$
\sup_{N \geq 1, v \in H} |V_N(v)| + \|DV_N(v)\|_H + \|B_N(v)\|_H < \infty.
$$

Let \(\mathbb{E}\) be the expectation with respect to the noise. With the above estimates, for a function \(f\) on \(E\) such that \(f(v) = f^\dagger(\langle v, h_1 \rangle_H, \ldots, \langle v, h_M \rangle_H)\) with some \(M \geq 1\) and \(f^\dagger \in C^1_c(\mathbb{R}^M)\), we can show that

$$
\lim_{N \to \infty} \mathbb{E}[f(u^v_N(t))] = \mathbb{E}[f(u^v(t))].
$$

Noting that \((V^1_N, B^\dagger_N)\) fulfills (2.9), the previous step implies that

$$
\int_E \mathbb{E}[f(u^v_N(t))] e^{-2V_N(v)} \mu(dv) = \int_E f(v) e^{-2V(v)} \mu(dv).
$$

Because \(f^\dagger\) is compactly supported, by taking \(N \to \infty\) we get \(\int_E \mathbb{E}[f(u^v(t))] \nu(dv) = \int_E f(v) \nu(dv)\). Applying Cauchy–Schwartz inequality,

$$
\int_E \{\mathbb{E}[f(u^v_N(t))]\}^2 \nu(dv) \leq \int_E \mathbb{E}[f^2(u^v_N(t))] \nu(dv) = \int_E f^2(v) \nu(dv).
$$
With this inequality and the fact that the finite-dimensional dependent functions is dense in \( L^2(\nu) \), we can conclude that \( \nu \) is invariant for \( \{u^\nu(t); t \geq 0\} \).

In case that \( B \equiv 0 \), we can prove the reversibility of \( \nu \) in the same way, only to observe that now the finite-dimensional approximation \( X_t \) is a symmetric process, so that \( e^{-2V(t)} \prod_{k=1}^N \Psi_k(x_k)dx_k \) becomes reversible.

The stationary measure obtained in Lemma 2.5 is of infinite mass. To overcome this difficulty, we define a probability measure \( \pi \) on \( \Xi \) as

\[
\pi(d\xi) = Z^{-1} \exp(-2V(\xi))\mu_0(dv_\xi) \otimes Q(d\xi(0)), \quad (2.10)
\]

where \( v_\xi \in E_0 \) is determined by the one-to-one map from \( \Xi \) to \( \Sigma \times E_0 \), and \( Z \) is the normalization constant. Our aim is to show that \( \pi \) is stationary for \( \{P_t; t \geq 0\} \).

**Proposition 2.6.** \( \pi \) is a stationary and ergodic probability measure for \( \{P_t; t \geq 0\} \). Moreover, if \( B \equiv 0 \), then \( \pi \) is reversible.

To prove Proposition 2.6, we need to introduce the class of smooth functions on \( \Xi \). Let \( C \) be the dense subspace of \( H \) defined as

\[
C = \{h \in H \mid h \in C^2[0,1], h'(0) = 0, h'(1) = 0, \langle h, 1 \rangle_H \neq 0\}, \quad (2.11)
\]

Pick arbitrarily some \( \psi \in L^\infty(\Sigma; Q) \), \( n \geq 1 \), \( h_1, \ldots, h_n \in C \) and \( \ell_k \in C^\infty_b(\mathbb{R}^n) \) such that \( \ell_k \) together with all its derivatives belongs to \( L^1(\mathbb{R}^n; dx) \). Consider the function

\[
f(\xi) = \int_\mathbb{R} \psi(\tau_0 \sigma)\ell(v - \theta 1)d\theta, \quad \forall \xi = \tau_{v(\cdot)} \sigma \in \Xi, \quad (2.12)
\]

where \( \ell(v) = \ell_k(\langle v, h_1 \rangle_H, \ldots, \langle v, h_n \rangle_H) \) for \( v \in E \). Let \( E_0(\Xi) \) be the collection of all \( f \) in \( (2.12) \), and call its linear span \( E(\Xi) \) the smooth function class on \( \Xi \).

\( E(\Xi) \) is dense in \( L^2(\Xi; \pi) \). To see that, pick \( g \in L^2(\Xi; \pi) \) and suppose that \( \langle g, f \rangle_\pi = 0 \) for all \( f \in E_0(\Xi) \). By virtue of \( (2.10) \) and \( (2.12) \), it implies

\[
\frac{1}{Z} E_Q \left\{ \int_{E_0} \mu_0(dv) \int_\mathbb{R} e^{-2V(\tau_{v(\cdot)} \sigma)} g(\tau_{v(\cdot)} \sigma)\psi(\tau_0 \sigma)\ell(v - \theta 1)d\theta \right\} = 0
\]

holds for all \( \psi \) and \( \ell \) satisfying the conditions above \( (2.12) \). Applying the change of variable \( \sigma = \tau_{\cdot - \theta \sigma'} \), we get from the stationarity of \( Q \) under \( \tau_0 \) that

\[
\frac{1}{Z} E_Q \left\{ \int_{E_0} \mu_0(dv) \int_\mathbb{R} e^{-2V(\tau_{v(\cdot) - \sigma_1 \sigma'}) g(\tau_{v(\cdot) - \sigma_1} \sigma')\psi(\sigma')\ell(v - \theta 1)d\theta} \right\} = 0.
\]

Since \( v - \theta 1 \) in this integral subjects to the infinite measure \( \mu \) defined in Lemma 2.5, we can rewrite the above equation as

\[
\frac{1}{Z} E_Q \left\{ \int_E e^{-2V(\tau_{v(\cdot)} \sigma')} g(\tau_{v(\cdot)} \sigma')\psi(\sigma')\ell(v)\mu(dv) \right\} = 0. \quad (2.13)
\]

From \( (2.13) \) we obtain that \( e^{-2V} g = 0 \) for \( Q \)-almost all \( \sigma \) and \( \mu \)-almost all \( v \), and thus \( g = 0 \) in \( L^2(\Xi, \pi) \). As \( E(\Xi) \) is the linear span of \( E_0(\Xi) \), it is dense in \( L^2(\Xi; \pi) \).
Proof of Proposition 2.6. We begin with pointing out that to prove the stationarity of $\pi$, it suffices to show $E_\pi[\mathcal{P}_t(f \cdot f')] = E_\pi[f \cdot f']$ for all $f, f' \in \mathcal{E}(\Xi)$. Indeed, by taking $f' = f$ we have $E_\pi[(\mathcal{P}_t f)^2] = E_\pi[\mathcal{P}_t(f^2)] = E_\pi[f^2]$, so $\mathcal{P}_t$ is contractive on $L^2(\Xi; \pi)$. Since $\mathcal{E}(\Xi)$ is dense in $L^2(\Xi; \pi)$, it is easy to obtain $E_\pi[\mathcal{P}_t f] = E_\pi f$ for all $f \in L^2(\Xi; \pi)$, thus $\pi$ is a stationary measure.

Now we prove that $E_\pi[\mathcal{P}_t(f \cdot f')] = E_\pi[f \cdot f']$ for $f, f' \in \mathcal{E}(\Xi)$. By the definition, it suffices to prove for $f, f' \in \mathcal{E}_0(\Xi)$. Suppose that $f, f'$ are defined by (2.12) with some $(\psi, \ell)$ and $(\psi', \ell')$ respectively. Observe that for $\xi = \tau_{\psi(x)}\ell$,

$$f \cdot f' (\xi) = \int_{\mathbb{R}^2} \psi(\tau_{\theta} \sigma) \psi'(\tau_{\theta + \theta'} \sigma) \ell(v) \ell'(v - (\theta + \theta') \mathbf{1}) d\theta d\theta'.$$

To simplify the notations, in this proof we write $\Psi_\ell(\sigma) = \psi(\tau_{\theta} \sigma)$ and $L_\theta(v) = \ell(v) \ell'(v - \theta \mathbf{1})$. With these notations we have

$$E_\pi[\mathcal{P}_t(f \cdot f')] = \frac{1}{Z} E_Q \left\{ \int_{\mathcal{E}_0} \mu_0(d\psi) \int_{\mathbb{R}^2} e^{-2V(\sigma, v)} \Psi_\psi(\tau_\theta \sigma) \mathbb{E} \left[ L_{\theta'}(u_{\sigma,v}(t) - \theta \mathbf{1}) \right] d\theta d\theta' \right\}.$$

Since $u_{\sigma,v}(t) - \theta \mathbf{1} = u_{\tau_{\theta} \sigma, v - \theta} \mathbf{1}(t)$, the change of variable $\sigma = \tau_{\theta} \sigma'$ yields that

$$E_\pi[\mathcal{P}_t(f \cdot f')] = \frac{1}{Z} E_Q \left\{ \int_{\mathcal{E}_0} \mu_0(d\psi) \int_{\mathbb{R}^2} e^{-2V(\sigma', v - \theta \mathbf{1})} \Psi_{\psi'}(\sigma') \mathbb{E} \left[ L_{\theta'}(u_{\sigma',v - \theta} \mathbf{1}(t)) \right] d\theta d\theta' \right\}.$$

With the same arguments as in calculating (2.13) we get

$$E_\pi[\mathcal{P}_t(f \cdot f')] = \frac{1}{Z} E_Q \left\{ \int_{\mathcal{E}_0} \mu_0(d\psi) \int_{\mathbb{R}^2} e^{-2V(\sigma, v)} \Psi_{\psi'}(\sigma') \mathbb{E} \left[ L_{\theta'}(u_{\sigma,v}(t)) \right] d\theta d\theta' \right\}.$$

Due to Lemma 2.5 the last integral equals to $E_{\pi^\sigma}[L_{\theta'}]$, so that

$$E_\pi[\mathcal{P}_t(f \cdot f')] = \frac{1}{Z} E_Q \left\{ \int_{\mathcal{E}_0} \mu_0(d\psi) \int_{\mathbb{R}} e^{-2V(\sigma, v)} \Psi_{\psi'}(\sigma') L_{\theta'}(v) d\theta' \right\}.$$

The desired equation $E_\pi[\mathcal{P}_t(f \cdot f')] = E_\pi[f \cdot f']$ then follows.

In case that $B = 0$, the reversibility of $\pi$ can be proved in the same way, only to notice that $\pi^\sigma$ is now reversible to the semigroup in frozen environment.

To see the ergodicity, pick $G \subseteq \Xi$ such that $\pi(G) > 0$ and $\mathcal{P}_t 1_G = 1_G$ for some $t > 0$, and we show that $\pi(G) = 1$. For every $\sigma \in \Sigma$, define $G_\sigma = \{ v \in E; \tau_{\psi(x)}\ell \sigma \in G \}$. Take a strictly positive $f \in L^1(\mathbb{R}; dx)$ and observe that

$$\frac{1}{Z} \int_{\mathbb{R}} \left\{ E_Q \left[ \int_{\mathcal{E}_0} e^{-2V(\sigma, v)} 1_{G_\sigma}(v) \mu_0(dv) \right] \cdot f(c) \right\} dc = \pi(G) \cdot \int_{\mathbb{R}} f(c) dc > 0.$$

Noting that $1_{G_\sigma}(v) = 1_{G_{(\tau_{\psi(x)}\ell - \sigma)}}(v - c \mathbf{1})$, the above equation can be written as

$$\int_{\mathbb{R}} \left\{ E_Q \left[ \int_{\mathcal{E}_0} e^{-2V(\tau_{\psi(x)}\ell - \sigma, v - c \mathbf{1})} 1_{G_{(\tau_{\psi(x)}\ell - \sigma)}}(v - c \mathbf{1}) \mu_0(dv) \right] \cdot f(c) \right\} dc > 0.$$
By the \( \tau_c \)-invariance of \( \mathbb{Q} \) and the same strategy used in \([2,13]\) we get

\[
E_Q \left[ \int_{E} e^{-2V(\sigma,v)} 1_{G_\sigma}(v)f(-v(0)) \mu(dv) \right] > 0,
\]

thus \( \mathbb{Q}(\sigma; \mu(G_\sigma) = 0) < 1 \). The \( \tau_c \)-invariance of \( \{ \sigma; \mu(G_\sigma) = 0 \} \) then implies that it is \( \mathbb{Q} \)-null, thanks to the ergodicity. Since \( \mu \) is absolutely continuous with respect to \( \pi^\sigma \), we know further that \( \mathbb{Q}(\sigma; \pi^\sigma(G_\sigma) = 0) = 0 \). Noting that for fixed \( \sigma \), \([1,11]\) satisfies the conditions mentioned in \([18\text{, Sect. } 1]\), hence from \([18\text{, Corollary } 1.1 \text{ and Theorem } 1.3]\), \( u^\sigma(t) \) is strong Feller and irreducible. Therefore, its transition probability \( P^\sigma(t; v, \cdot) \) is equivalent to its stationary measure \( \pi^\sigma \) for all \( v \) and \( t \), so that \( \mathbb{Q}(\sigma; P^\sigma(t; v, G_\sigma) = 0) = 0 \). Meanwhile, by \([2,5]\),

\[
0 = \langle 1_{G^c}, P_t 1_{G} \rangle = \frac{1}{Z} E_Q \left\{ \int_{E_0} [1 - 1_{G_\sigma}(v)] e^{-2V(\sigma,v)} P^\sigma(t; v, G_\sigma) \mu_0(dv) \right\}.
\]

As \( e^{-2V(\sigma,v)} P^\sigma(t; v, G_\sigma) \) is strictly positive for every \( v, t \) and almost all \( \sigma \), the above equation implies that \( \mathbb{Q}(\sigma; \mu_0(G_\sigma) = 1) = 1 \), and \( \pi(G) = 1 \) follows directly.

The last part of this section is devoted to the generator of \( \mathcal{P}_t \). Although \( \mathcal{P}_t \) is not strongly continuous under the topology of \( C_0(\Xi) \) (cf. \([3]\)), due to the stationarity of \( \pi \) we can extend \( \mathcal{P}_t \) to a \( C_0 \) semigroup of contractions on \( L^2(\Xi; \pi) \). Denote the extension still by \( \mathcal{P}_t \), and define its generator \( (\text{dom}(\mathcal{K}), \mathcal{K}) \) through Hille–Yosida theorem. Recall that \( \mathcal{K} \) is unbounded and closed, and we say \( A \subseteq \text{dom}(\mathcal{K}) \) is a core if \( A \) is dense in \( \text{dom}(\mathcal{K}) \) and \( \mathcal{K} \) coincides with the closure of \( \mathcal{K}|_A \). In the next proposition, we compute \( \mathcal{K} \) on the smooth function class on \( \Xi \) and show that it forms a core.

**Proposition 2.7.** \( \mathcal{E}(\Xi) \) forms a core of \( \mathcal{K} \), and for all \( f \in \mathcal{E}(\Xi) \),

\[
\mathcal{K}f(\xi) = \frac{1}{2} \langle \partial_\xi^2 [Df(\xi)], v_\xi \rangle_H - \langle Df(\xi), D\mathbb{V}(\xi) + B(\xi) \rangle_H + \frac{1}{2} \text{Tr}[D^2f(\xi)].
\]  

Proposition \([2,7]\) is proved along the strategy in \([3]\), where the maximal dissipativity for a class of Kolmogorov operators is discussed. We first prove the parallel result for a linear equation in Lemma \([2,8]\) and then extend it to the nonlinear case.

To discuss the linear case, consider an Ornstein–Uhlenbeck process \( \{ u^\sigma_0(t, \cdot) \in E; t \geq 0 \} \) with a given initial condition \( v \in E \) satisfying that

\[
u^\sigma_0(t) \equiv S_t v + \int_{0}^{t} S_{t-s} dW_s,
\]

where \( W_s \) is the cylindrical Brownian motion appeared in \([13,11]\), and \( \{ S_t; t \geq 0 \} \) is the semigroup on \( H \) generated by \( \frac{1}{2} \partial_x^2 \) with Neumann boundary condition. Since \( u^\sigma_0(t) \) solves \([1.11]\) when \( D\mathbb{V} + B \equiv 0 \), it is a continuous \( E \)-valued Markov
process. Denote by \( \{ T^t_0 \}; t \geq 0 \) the Markov semigroup determined by \( u^0(t) \) on \( B_0(E) \). In imitation of (2.5), for \( f \in B_0(\Xi) \) and \( t \geq 0 \) we define
\[
T_tf(\xi) = T^t_0 f^{(0)}(v_\xi), \quad \forall \xi \in \Xi.
\]
In view of Proposition 2.6, \( T_t \) possesses a reversible measure \( \pi_0(d\xi) = Z^{-1} \exp(-2V(\xi)) \pi(d\xi) \).
Write \( \mathcal{H}_{\pi_0} = L^2(\Xi; \pi_0) \), and extend \( \{ T_t; t \geq 0 \} \) to a strongly continuous semigroup of contractions on \( \mathcal{H}_{\pi_0} \). Denote by \((\text{dom}(\mathcal{L}), \mathcal{L})\) its generator on \( \mathcal{H}_{\pi_0} \). Paralleling to Proposition 2.7 we have the next lemma for \( \mathcal{L} \) and \( \pi_0 \).

**Lemma 2.8.** \( \mathcal{E}(\Xi) \) forms a core of \( \mathcal{L} \), and for all \( f \in \mathcal{E}(\Xi) \), \( \mathcal{L}f(\xi) = \mathcal{L}^0 f^{(0)}(v_\xi) \) where \( \mathcal{L}^0 \) is the Ornstein–Uhlenbeck operator defined as
\[
\mathcal{L}^0 f(v) = \frac{1}{2} \langle \ell^2 Df(v), v \rangle_H + \frac{1}{2} \text{Tr} [D^2f(v)].
\]

**Proof.** First we present a basic estimate. Suppose that \( f(v) = f^t(\langle v, h_1 \rangle_H, \ldots, \langle v, h_n \rangle_H) \) for all \( v \in E \), where \( n \geq 1 \), \( f^t \in C^\infty_b(\mathbb{R}^n) \) and \( h_1, \ldots, h_n \in \mathcal{C} \) are chosen arbitrarily. Let \( M = \max \{ \| \partial_\alpha f^t \|_\infty \} \), where the maximum is taking over all positive \( n \)-multiple indexes \( \alpha \) such that \( |\alpha| \leq 3 \). For such \( f \), we have (cf. [3, Corollary 2.3])
\[
\sup_{v \in E} \frac{1}{1 + \| v \|^2_H} \left| \frac{T^t_0 f(v) - f(v)}{t} - \mathcal{L}^0 f(v) \right| \leq MC_t, \tag{2.15}
\]
where \( C_t \) is a constant depending on the \( h_i \)'s, satisfying that \( C_t \to 0 \) when \( t \downarrow 0 \) for fixed \( h_1, \ldots, h_n \in \mathcal{C} \). We here give the proof of (2.15) only for the case \( n = 1 \), since for larger \( n \) the calculations are the same. When \( n = 1 \), we write \( f(v) = f^t(\langle v, h \rangle_H) \), and define \( Q_{t,h} = f^t_0(\langle S_t h, dW(\cdot) \rangle_H) \). With \( \mathbb{E} \) being the expectation with respect to the noise, we have \( \mathbb{E}[Q_{t,h}] = 0 \) and
\[
\begin{align*}
|T^t_0 F(v) - F(v) - t \mathcal{L}^0 F(v)| \\
&\leq \mathbb{E} \left| (f(\langle v, Sth \rangle_H + Q_{t,h}) - f(\langle v, Sth \rangle_H)) - \frac{t}{2} \cdot f''(\langle v, h \rangle_H) \| h \|^2_H \right| \\
&+ \left| f(\langle v, Sth \rangle_H) - f(\langle v, h \rangle_H) - t \cdot f'(\langle v, h \rangle_H) \left< v, \frac{1}{2} h'' \cdot \right> \right| \\
&\leq \frac{1}{2} |f''|_\infty \mathbb{E} \left[ \| Q^2_{t,h} \|_H - t \| h \|^2_H \right] + \frac{1}{6} |f'''|_\infty \mathbb{E} \left[ |Q_{t,h}|^3 \right] \\
&+ |f'|_\infty \| v \|^2_H \cdot \| S_t h - h - \frac{t}{2} h'' \|_{2,h} + \frac{1}{2} |f''|_\infty \| v \|^2_H \cdot \| S_t h - h \|^2_H.
\end{align*}
\]

Since \( h \in \text{dom}(\frac{1}{2} D^2) \), (2.15) follows from direct calculation.

Now pick some \( f \) in the form of (2.12) and notice that for all \( \sigma \in \Sigma \),
\[
f^\sigma(v) = \int_\mathbb{R} \psi(\tau_\sigma \theta)(v - \theta) d\theta, \quad \forall v \in E.
\]
In view of the conditions on \( \psi \) and \( \ell \), it is easy to observe that (2.15) holds for each \( f^\sigma \) with common constants \( M \) and \( C_t \), hence
\[
\frac{1}{1 + \| v_\xi \|^2_H} \left| \frac{T_tf(\xi) - f(\xi)}{t} - \mathcal{L}^0 f^{(0)}(v_\xi) \right| \leq MC_t.
\]
Applying dominated convergence theorem, we obtain that
\[
\mathcal{H}_{\pi_0} \lim_{t \downarrow 0} \frac{T_t f - f}{t} = \mathcal{L}^0 f^{(0)}(v_\xi), \quad \forall f \in \mathcal{E}^0(\Xi).
\]
(2.16)

As \(\mathcal{E}(\Xi)\) is the linear span of \(\mathcal{E}^0(\Xi)\), (2.16) holds for all \(f \in \mathcal{E}(\Xi)\), therefore \(\mathcal{E}(\Xi) \subseteq \text{dom}(\mathcal{L})\) and \(\mathcal{L} f(\xi) = \mathcal{L}^0 f^{(0)}(v_\xi)\) for \(f \in \mathcal{E}(\Xi)\).

We are left to show that \(\mathcal{E}(\Xi)\) is a core. By [4, p. 17, Proposition 1.3.3], it suffices to show that \(\mathcal{E}(\Xi)\) is preserved under \(\{T_t; t \geq 0\}\). Notice that for \(h \in \mathcal{C}\),
\[
\langle u_0(t), h \rangle_H = \langle v, S_t h \rangle_H + Q_{t,h}
\]
and \(S_t h\) still belongs to \(\mathcal{C}\). Therefore, for \(f\) in the form of (2.12),
\[
T_t^0 f^{\sigma}(v) = \mathbb{E}[f^{\sigma}(u_0(t))] = \int_{\mathbb{R}} \psi(\tau_0 \sigma) \mathbb{E}[\ell^1(v_{t,h} - \theta(\tilde{h})_H + \tilde{Q}_{t,h})] d\theta,
\]
where \(v_{t,h} = (\langle v, S_t h_1 \rangle_H, \ldots, \langle v, S_t h_n \rangle_H), \langle \tilde{h} \rangle_H = (\langle h_1 \rangle_H, \ldots, \langle h_n \rangle_H)\) are deterministic \(\mathbb{R}^n\)-vectors, and \(\tilde{Q}_{t,h} = (Q_{t,h_1}, \ldots, Q_{t,h_n})\) is a random vector. \(T_t f \in \mathcal{E}(\Xi)\) then follows from the conditions on \(\psi\) and \(\ell^1\), and consequently \(T_t[\mathcal{E}(\Xi)] \subseteq \mathcal{E}(\Xi)\).

From Lemma 2.3, \(\mathcal{L}(\mathcal{F}_2) = 2f \cdot \mathcal{L}f + \|\mathcal{D}f\|_H^2\) holds for \(f \in \mathcal{E}(\Xi)\), and the stationarity of \(\pi_0\) implies that \(\mathbb{E}_{\pi_0}[\mathcal{L}(\mathcal{F}_2)] = 0\), so that Dirichlet form of \(\mathcal{L}\) reads
\[
\langle f, -\mathcal{L}f \rangle_{\pi_0} = \frac{1}{2} \int_{\Xi} \|\mathcal{D}f(\xi)\|_H^2 \pi_0(d\xi), \quad \forall f \in \mathcal{E}(\Xi).
\]
(2.17)

Let \(\mathcal{H}_\pi = L^2(\Xi, \pi)\), and \(\langle \cdot, \cdot \rangle_{\pi}, \| \cdot \|_{\pi}\) be the related inner product and norm. By (A2), \(\| \cdot \|_\pi\) and \(\| \cdot \|_{\pi_0}\) are equivalent, so that elements in \(\mathcal{H}_\pi\) can be identified with those in \(\mathcal{H}_{\pi_0}\). With this observation, we close this section with the proof to Proposition 2.7.

**Proof of Proposition 2.7.** First recall the definition of differentiable function on \(\Xi\) in Definition 2.3. Let \(C^1_b(\Xi)\) denote the class of all differentiable functions \(f\) on \(\Xi\) such that \(Df\) is continuous and uniformly bounded in \(H\). Define
\[
\mathcal{K}^\sigma f = \mathcal{L}f - \langle \langle Df, D\nu \rangle_{\sigma} + B \rangle_{H}, \quad \forall f \in \text{dom}(\mathcal{L}) \cap C^1_b(\Xi).
\]
Noticing that \(\mathcal{E}(\Xi) \subseteq \text{dom}(\mathcal{L}) \cap C^1_b(\Xi)\) and that \(\mathcal{K}^\sigma\) satisfies (2.14) for \(f \in \mathcal{E}(\Xi)\), to verify the explicit form (2.14) for \(\mathcal{K}\) we only need to show that
\[
\mathcal{H}_\pi - \lim_{t \downarrow 0} \frac{\mathcal{P}_t f - f}{t} = \mathcal{K}^\sigma f, \quad \forall f \in \text{dom}(\mathcal{L}) \cap C^1_b(\Xi).
\]
(2.18)

Indeed, observing that \(u^{\sigma,v}(t) - u_0(t) = \int_0^t S_{t-r}[-D\nu(\xi_r) - B(\xi_r)]dr\), for any \(f \in C^1_b(\Xi)\) and fixed \(\sigma, v\) we have
\[
\lim_{t \downarrow 0} \frac{\mathcal{P}_t f^{\sigma}(v) - T_t ^0 f^{\sigma}(v)}{t} = \lim_{t \downarrow 0} \mathbb{E} \left\langle Df(\xi), -\frac{1}{t} \int_0^t S_{t-r}[-D\nu(\xi_r) + B(\xi_r)]dr \right\rangle_H + o(1)
\]
\[
= \langle Df^{\sigma}(v), D\nu(\tau_{v(\xi)}) + B(\tau_{v(\xi)}) \rangle_H.
\]
By (A2) and dominated convergence theorem, for $f \in C_b^1(\Xi)$ we obtain

$$\mathcal{H}_n \lim_{t \downarrow 0} \frac{P_t f - T_t f}{t} = -\langle Df, DV + B \rangle_H. \quad (2.19)$$

As $\pi_0$ and $\pi$ are mutually equivalent, (2.18) follows from (2.16) and (2.19) directly.

Due to the Lumer–Phillips theorem (see, e.g., [21] and [3, p. 17, Proposition 1.3.1]), to show that $\mathcal{E}(\Xi)$ is a core, it suffices to prove that $(\lambda - \kappa)\mathcal{E}(\Xi)$ is dense in $\mathcal{H}_\pi$ for some $\lambda > 0$. We first prove it under an additional condition. By (A1), for $\mathbb{Q}$-almost all $\sigma$, $DV(\sigma, \cdot) + B(\sigma, \cdot)$ can be extended to some $U^\sigma \in C_b(H; H)$ such that $\|U^\sigma\|_H$ is uniformly bounded in $\sigma$ and $v$. Assume further that (A1') $U^\sigma \in C_b^2(H; H)$ and $\sup_{\Sigma \times H} |D^2 U^\sigma(v)|_{L(H; H)} < \infty$.

Now for fixed $\sigma$, (1.3.1) becomes a stochastic heat equation with twice differentiable nonlinear term, thus obviously $\mathcal{P}_t^\sigma [C_b^1(H)] \subseteq C_b^1(H)$. Furthermore, due to [18, Theorem 1.2], there is some constant $C$ such that

$$\sup_H \|D\mathcal{P}_t^\sigma f\|_H \leq C \max\{t^{-1/2}, 1\} \cdot \sup_H |f|, \forall f \in C_b^1(H).$$

Fix $g \in \mathcal{E}(\Xi)$, $\lambda > 0$ and define $f = (\lambda - \kappa)^{-1} g$. We show that $f \in \text{dom}(\mathcal{L}) \cap C_b^1(\Xi)$. Notice the following formula holds for $f$

$$f(\xi) = \int_0^\infty e^{-\lambda t} \cdot \mathcal{P}_t g(\xi) dt, \forall \xi \in \Xi. \quad (2.20)$$

By the above estimates and dominated convergence theorem, $f \in C_b^1(\Xi)$ and $\|Df(\xi)\|_H$ is bounded from above by $C_\lambda \sup_{\Xi} |f|$ with some constant $C_\lambda$. Observe that

$$\frac{T_s f(\xi) - f(\xi)}{s} = \frac{P_s f(\xi) - f(\xi)}{s} + \frac{T_s f(\xi) - P_s f(\xi)}{s}. \quad (2.21)$$

Since $f \in \text{dom}(\mathcal{K})$, the $\mathcal{H}_\pi$-limit of the first term in the right-hand side of (2.21) exists when $s \downarrow 0$. Since $f \in C_b^1(\Xi)$, (2.19) yields that the second term converges in $\mathcal{H}_\pi$. Noting that $\mathcal{H}_\pi_0$ and $\mathcal{H}_\pi$ have equivalent norm, we have $f \in \text{dom}(\mathcal{L})$.

The previous proof now implies that $\mathcal{K} f = \mathcal{L} f - \langle Df, DV + B \rangle_H$. Since $\mathcal{E}(\Xi)$ is a core of $\mathcal{L}$, we can pick $f_k \in \mathcal{E}(\Xi)$ such that $f_k \rightarrow f$ and $\mathcal{L} f_k \rightarrow \mathcal{L} f$, both in $\mathcal{H}_\pi_0$. By (2.17), $\|D(f_k - f)\|_H$ vanishes in $\mathcal{H}_\pi_0$ and $\mathcal{H}_\pi$. Therefore,

$$E_\pi |\mathcal{K}(f_k - f)|^2 \leq 2E_\pi |\mathcal{L}(f_k - f)|^2 + 2E_\pi |\langle D(f_k - f), DV + B \rangle_H|^2 \rightarrow 0$$

as $k \rightarrow \infty$. Consequently, $\|g - (\lambda - \kappa)f_k\|_\pi \rightarrow 0$ and $(\lambda - \kappa)[\mathcal{E}(\Xi)]$ is dense in $\mathcal{H}_\pi$.

If (A1') fails to hold, we need to pick an approximating sequence. Indeed, suppose that we can find a sequence $(V_n, B_n)$ satisfying (A1'), (A2), (A4) and that

$$\lim_{n \rightarrow \infty} E_\pi \|DV + B - DV_n - B_n\|^2_H = 0. \quad (2.22)$$

16
Let \( \mathcal{K}_n \) be the generator of the environment process related to the solution to \( \mathbf{1.1} \) with \((\mathbf{V}, \mathbf{B})\) replaced by \((\mathbf{V}_n, \mathbf{B}_n)\). Fix some \( g \in \mathcal{E}(\Xi) \) and let \( f_n = (\lambda - \mathcal{K}_n)^{-1} g \). By the previous step, \( f_n \in \text{dom}(\mathcal{L}) \cap C^1_b(\Xi) \), so that we have

\[
(\lambda - \mathcal{K}) f_n = g + (\kappa_n - \mathcal{K}) f_n = g + \langle \mathcal{D} \mathbf{V}_n + \mathbf{B}_n - \mathcal{D} \mathbf{V} - \mathbf{B}, \mathcal{D} f_n \rangle_H.
\]

Notice that for \( f \in \text{dom}(\mathcal{L}) \cap C^1_b(\Xi) \) we have \( \mathcal{K}[f^2] = 2f \cdot \mathcal{K}f + \|\mathcal{D}f\|_H^2 \). With the same way of computing the Dirichlet form for \( \mathcal{L} \) in \( \mathbf{2.17} \), we get that

\[
(f, -\mathcal{K}f)_{\pi} = 2^{-1} \mathcal{E}_\pi [\|\mathcal{D}f\|_H^2].
\]

(2.24)

In view of \( \mathbf{2.23} \) and \( \mathbf{2.24} \),

\[
\lambda \|f_n\|_\pi^2 + 2^{-1} \mathcal{E}_\pi [\|\mathcal{D}f_n\|_H^2] = \langle g, f_n \rangle_{\pi} + \mathcal{E}_\pi [\langle \mathcal{D} \mathbf{V}_n + \mathbf{B}_n - \mathcal{D} \mathbf{V} - \mathbf{B}, \mathcal{D} f_n \rangle_H \cdot f_n].
\]

By virtue of \( \mathbf{2.20} \), \( \sup_{\Xi} |f_n| \leq \lambda^{-1} \sup_{\Xi} |g| \) holds for all \( n \), thus

\[
\frac{\lambda}{2} \mathcal{E}_\pi [\|\mathcal{D}f_n\|_H^2] \leq \sup_{\Xi} \|g\|^2 + \sup_{\Xi} |g| : \mathcal{E}_\pi [\langle \mathcal{D} \mathbf{V}_n + \mathbf{B}_n - \mathcal{D} \mathbf{V} - \mathbf{B}, \mathcal{D} f_n \rangle_H].
\]

Using Cauchy–Schwarz inequality we obtain that

\[
\frac{\lambda}{4} \mathcal{E}_\pi [\|\mathcal{D}f_n\|_H^2] \leq \sup_{\Xi} \|g\|^2 + 4 \sup_{\Xi} |g|^2 : \mathcal{E}_\pi [\|\mathcal{D} \mathbf{V}_n + \mathbf{B}_n - \mathcal{D} \mathbf{V} - \mathbf{B}\|_H^2].
\]

Hence, \( \{\mathcal{E}_\pi[\|\mathcal{D}f_n\|_H^2]; n \geq 1\} \) is a uniformly bounded sequence. By \( \mathbf{2.23} \) and \( \mathbf{2.22} \), \( (\lambda - \mathcal{K}) f_n \) converges to \( g \) in the topology of \( H_\pi \), thus \( (\lambda - \mathcal{K}) \mathcal{E}(\Xi) \) is dense.

We are left to show the existence of \((\mathbf{V}_n, \mathbf{B}_n)\). Using the strategy in the proof of Lemma \( \mathbf{2.5} \) for fixed \( \sigma \) without loss of generality we can assume \((V(\sigma, \cdot), B(\sigma, \cdot))\) to be in the form of \( \mathbf{2.8} \) with some \( V^1(\sigma, \cdot) \in C^1_b(\mathbb{R}^N) \) and \( B^1(\sigma, \cdot) \in C_b(\mathbb{R}^N; \mathbb{R}^N) \). Pick smooth functions \( V_n^1(\sigma, \cdot) \) and \( B_n^1(\sigma, \cdot) \) such that \( (\nabla V_n^1 + B_n^1)(\sigma, \cdot) \) converges to \( (\nabla V^1 + B^1)(\sigma, \cdot) \) in a point-wise sense, \( \sup_{\Xi \times \mathbb{R}^N} |\nabla V_n^1 + B_n^1| \) is uniformly bounded from above and \( \mathbf{2.23} \) holds with \( V_n^1(\sigma, \cdot) \) and \( B_n^1(\sigma, \cdot) \).

Then, we get the desired sequence \((V_n(\sigma, \cdot), B_n(\sigma, \cdot))\) from \( V_n^1(\sigma, \cdot) \) and \( B_n^1(\sigma, \cdot) \) with \( \mathbf{2.8} \).

3 Central limit theorem for \( u(t) / \sqrt{t} \)

Before giving the proof of Theorem \( \mathbf{1.1} \), we introduce two Hilbert spaces \( \mathcal{H}_1 \) and \( \mathcal{H}_{-1} \) related to the operator \( \mathcal{K} \) (cf. \( \mathbf{11} \) Sect. 2.2)).

Notice that \( \mathbf{2.21} \) defines a semi-norm \( \| \cdot \|_1^2 \) on \( \mathcal{E}(\Xi) \). Let \( \mathcal{J}_1 = \mathcal{E}(\Xi)/ \sim_1 \), where \( \sim_1 \) is the equivalence relation defined by \( f \sim_1 g \iff \|f - g\|_1 = 0 \). \| \cdot \|_1 \) naturally extends to a norm on \( \mathcal{J}_1 \), and let \( \mathcal{H}_1 \) be the completion of \((\mathcal{J}_1, \| \cdot \|_1)\). \( \mathcal{H}_1 \) becomes a Hilbert space under the inner product given by polarization:

\[
(f, g)_1 \triangleq \frac{1}{4} (\|f + g\|_1^2 + \|f - g\|_1^2).
\]
Noting that by (2.24), \( D \) can be extended to a linear operator defined on \( H_1 \) and taking values in \( L^2(\Xi, H; \pi) \). We denote the extension still by \( D \). Meanwhile, since for each \( f \in \mathcal{E}(\Xi) \), \( f^\sigma \) is finite-dimensional dependent, by applying the classical Itô formula for finite-dimensional semi-martingales we get

\[
f(\xi_t) - f(\xi_0) = \int_0^t \mathcal{K} f(\xi_r) dr + \int_0^t \langle D f(\xi_r), dW_r \rangle_H, \forall f \in \mathcal{E}(\Xi). \tag{3.1}
\]

The dual space \( \mathcal{H}_{-1} \) of \( \mathcal{H}_1 \) is defined as follows. For \( f \in \mathcal{H}_\pi \), let

\[
\| f \|_{-1}^2 = \sup_{g \in \mathcal{E}(\Xi)} \left\{ \langle f, g \rangle_\pi - \| g \|_1^2 \right\}.
\]

Let \( \mathcal{F}_0 = \{ f \in \mathcal{H}_\pi, \| f \|_{-1} < \infty \} \) and \( \mathcal{F}_{-1} = \mathcal{F}_0 / \sim_{-1} \), where \( \sim_{-1} \) is the equivalence relation defined by \( f \sim_{-1} g \iff \| f - g \|_{-1} = 0 \). Let \( \mathcal{H}_{-1} \) be the completion of \( (\mathcal{F}_{-1}, \| \cdot \|_{-1}) \), which is also a Hilbert space under the inner product \( \langle \cdot, \cdot \rangle_{-1} \) defined through polarization. The following variational formula holds for \( \| \cdot \|_{-1} \):

\[
\| f \|_{-1} = \sup_{g \in \mathcal{E}(\Xi)} \left\{ \frac{\langle f, g \rangle_\pi}{\| g \|_1^2}, \| g \|_1 \neq 0 \right\}, \forall f \in \mathcal{H}_\pi \cap \mathcal{H}_{-1}. \tag{3.2}
\]

Recall that \( \Sigma_0 = \{ \sigma \in \Sigma, \tau_c \sigma = \sigma, \forall c \in \mathbb{R} \} \). Observe that when \( \sigma \notin \Sigma_0 \), in view of Lemma 2.1, \( v_{\xi_t} = u^{\sigma, v}(t, \cdot) - u^{\sigma, v}(t, 0) \), hence the weak form of (1.1) reads

\[
\langle u^{\sigma}(t), \varphi \rangle_H = \langle u^{\sigma}(0), \varphi \rangle_H + \int_0^t \mathcal{U}_\varphi(\xi_r) dr + \langle W_t, \varphi \rangle_H, \tag{3.3}
\]

where \( \varphi \in C^2[0, 1] \) is a test function such that \( \varphi'(0) = \varphi'(1) = 0 \), and

\[
\mathcal{U}_\varphi(\xi) = \frac{1}{2} \langle v_{\xi}, \partial^2_{\xi} \varphi \rangle_H - \langle D \mathcal{V}(\xi) + B(\xi), \varphi \rangle_H. \tag{3.4}
\]

When \( \sigma \in \Sigma_0 \) we have \( v_{\xi_t} \equiv 0 \) and (3.3) fails to hold. However, from (2.1), \( \Sigma_0 \) is a \( \mathbb{Q} \)-null set here, therefore (3.4) holds \( \mathbb{Q} \)-almost surely and this is sufficient for the \( L^1(\mathbb{Q}) \) convergence in Theorem 1.1.

Let \( (\text{dom}(\mathcal{K}), \mathcal{K}^*) \) be the adjoint operator of \( \mathcal{K} \) on \( \mathcal{H}_\pi \). By the standard arguments in [9] Sects. 2.6, 2.7, 9.5, to get a central limit theorem for \( \langle u^{\sigma}(t), \varphi \rangle_H \) it is necessary to show that \( \mathcal{E}(\Xi) \) is also a core of \( \mathcal{K}^* \), \( \mathcal{K} \) satisfies a sector condition and \( \mathcal{U}_\varphi \in \mathcal{H}_{-1} \). We prove these results in this section.

**Proposition 3.1.** \( \mathcal{E}(\Xi) \) forms a core of \( \mathcal{K}^* \), and for all \( f \in \mathcal{E}(\Xi) \),

\[
\mathcal{K}^* f(\xi) = \frac{1}{2} \langle \partial^2_{\xi}[D f(\xi)], v_{\xi} \rangle_H - \langle D f(\xi), D \mathcal{V}(\xi) - B(\xi) \rangle_H + \frac{1}{2} \text{Tr}[D^2 f(\xi)]. \tag{3.5}
\]

**Proof.** Let \( \hat{u}^{\sigma, v}(t, \cdot) \) be the solution to (1.1) with \( B \) replaced by \(-B\), and \( \{\xi_t; t \geq 0\} \) be the corresponding environment process. By Proposition 2.6, \( \pi \) is stationary for \( \xi_t \), so that its Markov semigroup \( \{\mathcal{P}_t; t \geq 0\} \) is a \( C_0 \) semigroup.
of contractions on \( \mathcal{H}_\pi \). Let \( \hat{\mathcal{K}} \) be its generator. By Proposition 2.7, \( \hat{\mathcal{K}} \) satisfies (A4), and \( \mathcal{E}(\Xi) \) is a core of \( \hat{\mathcal{K}} \).

It suffices to show \( \mathcal{K}^* = \mathcal{K} \). From Proposition 2.6, \( \pi \) is reversible if \( B = 0 \), thus

\[
\langle \mathcal{K}f + \langle \mathcal{D}f, B \rangle_H, g \rangle_\pi = \langle f, \mathcal{K}^* g - \langle Dg, B \rangle_H \rangle_\pi, \quad \forall f, g \in \mathcal{E}(\Xi). \tag{3.6}
\]

Meanwhile, in view of (A4), for \( f \) and \( g \in \mathcal{E}(\Xi) \) we have

\[
E_\pi [\langle Dfg, B \rangle_H] = \frac{1}{2Z} E_Q \left\{ \int_{E_0} e^{-2V(\sigma,v)} \langle D[f^\sigma g^\sigma](v), B(\sigma,v) \rangle_H \mu_0(dv) \right\} = 0. \tag{3.7}
\]

Combing (3.6) and (3.7) shows that \( \hat{\mathcal{K}} = \mathcal{K}^* \) on \( \mathcal{E}(\Xi) \). Noting that \( \mathcal{E}(\Xi) \) is a core of \( \mathcal{K} \) and \( \mathcal{K}^* \) is always closed, this would imply that \( \hat{\mathcal{K}} \subseteq \mathcal{K}^* \). On the other hand, since \( \mathcal{K}^* \) is the adjoint of a Markov generator of a \( C_0 \) semigroup contractions, it is easy to show that \( \lambda - \mathcal{K}^* \) is invertible for all \( \lambda > 0 \). For all \( f \in \mathcal{H}_\pi \),

\[
f = (\lambda - \hat{\mathcal{K}}) \left[ (\lambda - \hat{\mathcal{K}})^{-1} f \right] = (\lambda - \mathcal{K}^*) \left[ (\lambda - \hat{\mathcal{K}})^{-1} f \right],
\]

therefore \( (\lambda - \mathcal{K}^*)^{-1} = (\lambda - \hat{\mathcal{K}})^{-1} \), and consequently \( \text{dom}(\mathcal{K}^*) = \text{dom}(\hat{\mathcal{K}}) \).

\[ \square \]

**Proposition 3.2.** The generator \( \mathcal{K} \) satisfies the sector condition, i.e.,

\[
\langle \mathcal{K}f, g \rangle_\pi^2 \leq C(-\mathcal{K}f, f) \langle -\mathcal{K}g, g \rangle_\pi, \quad \forall f, g \in \text{dom}(\mathcal{K}),
\]

where \( C = C(\mathcal{V}, B) \) is a finite constant depending only on \( \mathcal{V} \) and \( B \).

**Proof.** For \( f \in \text{dom}(\mathcal{K}) \cap \text{dom}(\mathcal{K}^*) \), let \( \mathcal{K}_a f = \frac{1}{2}(\mathcal{K}f + \mathcal{K}^* f) \) and \( \mathcal{K}_a f = \frac{1}{2}(\mathcal{K}f - \mathcal{K}^* f) \). By Proposition 3.1, it suffices to show for \( f, g \in \mathcal{E}(\Xi) \) that

\[
\langle \mathcal{K}_a f, g \rangle_\pi^2 \leq C(\mathcal{V}, B) E_\pi \|Df\|_H^2 E_\pi \|Dg\|_H^2.
\]

For a function \( g \) on \( E_0 \), let \( \langle g \rangle_{\mu_0} \triangleq E_{\mu_0}[g] \). By virtue of (A4),

\[
\langle -\mathcal{K}_a f, g \rangle_\pi = \frac{1}{Z} E_Q \left[ \int_{E_0} e^{-2V(\sigma,v)} \langle Df^\sigma(v), B(\sigma,v) \rangle_H (g^\sigma(v) - \langle g^\sigma \rangle_{\mu_0}) \mu_0(dv) \right].
\]

By Cauchy–Schwarz inequality and (A2) we obtain that

\[
\langle -\mathcal{K}_a f, g \rangle_\pi \leq C_1 \|f\|_1 \left( \frac{1}{Z} E_Q \left[ \int_{E_0} |g^\sigma(v) - \langle g^\sigma \rangle_{\mu_0}|^2 \mu_0(dv) \right] \right)^{1/2} \tag{3.8}
\]

with \( C_1 = 2 \sup \|B\|_H \exp(\sup \|V\|) \).

Now we apply the Poincaré inequality for Wiener measure. Let \( \hat{H} \) be the Cameron–Martin space \( \hat{H} = \{ h \in W^{1,2}([0,1]:\mathbb{R}) \mid h(0) = 0 \} \), equipped with the Cameron–Martin norm \( \|h\|_\hat{H} \triangleq \|\hat{h}\|_H \), where \( \hat{h} \) stands for the weak derivative of \( h \). For a function \( g \) on \( E_0 \) having the form \( g(v) = g^1(\langle v, h_1 \rangle_H, \ldots, \langle v, h_N \rangle_H) \) for some \( M \geq 1 \), \( g^1 \in C_0^1(\mathbb{R}^M) \) and \( h_i \in H \), recall its \( H \)-derivative \( D_H g \in H \) is

\[
D_H g(v) = \sum_{i=1}^M \partial_i g^1(\langle v, h_1 \rangle_H, \ldots, \langle v, h_N \rangle_H) \int_0^v \dot{h}_i(x) dx, \quad \forall v \in E_0,
\]
where \( \hat{h}_i = \int h_i(x)dx \in \hat{H} \). The Poincaré inequality for Wiener measure (see, e.g., [2, p. 226, Theorem 5.5.1]) yields that
\[
\int_{E_0} |g(v) - \langle g \rangle_{\mu_0}|^2 \mu_0(dv) \leq \int_{E_0} \|D_{\hat{H}}g(v)\|^2_{\hat{H}} \mu_0(dv).
\] (3.9)

To continue, write \( \vec{v}_h = (\langle v, h_1 \rangle_{\hat{H}}, \ldots, \langle v, h_M \rangle_{\hat{H}}) \) for shot. Observe that from the explicit formula for \( D_{\hat{H}}g(v) \) and Cauchy–Schwarz inequality,
\[
\|D_{\hat{H}}g(v)\|^2_{\hat{H}} = \int_0^1 \left[ \sum_{i=1}^M \partial_i g^1(\vec{v}_h) \int_y h_i(x)dx \right]^2 dy \leq \int_0^1 (1 - y) \int_y^1 \left[ \sum_{i=1}^M \partial_i g^1(\vec{v}_h) h_i(x) \right]^2 dxdy \leq \int_0^1 \left[ \sum_{i=1}^M \partial_i g^1(\vec{v}_h) h_i(x) \right]^2 dx = \|Dg(v)\|^2_H.
\]

Hence in the right-hand side of (3.9), we can substitute \( \|D_{\hat{H}}g(v)\|^2_{\hat{H}} \) with \( \|Dg(v)\|^2_H \).

As \( g \in \mathcal{E}(\Xi) \), by applying (3.9) to \( g_\sigma \) in (3.8) we conclude that
\[
\langle -K_a f, g \rangle_{\pi} \leq C_1 \|f\|_1 \|g\|_1,
\]
and the sector condition then follows.

**Proposition 3.3.** For every test function \( \varphi \in C^2[0,1] \) which satisfies that \( \varphi'(0) = 0, \varphi'(1) = 0 \), we have \( U_{\varphi} \) defined by (3.4) belongs to \( H^{-1} \).

**Proof.** In view of (3.2), we only need to show that there exists some finite constant \( C \) such that \( \langle U_{\varphi}, g \rangle_{\pi} \leq C\|g\|_1 \) holds for all \( g \in \mathcal{E}(\Xi) \). Taking \( f(v) = \langle v, \varphi \rangle_H \) in (A4), we obtain that for \( Q \)-almost all \( \sigma \),
\[
E_{\mu_0} \left[ e^{-2V(\sigma,v)} \langle B(\sigma,v), \varphi \rangle_H \right] = 0. \] (3.10)

Pick \( g \in \mathcal{E}(\Xi) \) and (3.10) implies that
\[
E_{\pi}[(B, \varphi)_H \cdot g] = \frac{1}{Z} E_{\pi} \left[ \int_{E_0} e^{-2V(\sigma,v)} \langle B(\sigma,v), \varphi \rangle_H \langle g^\sigma(v) - \langle g^\sigma \rangle_{\mu_0} \rangle_{\mu_0}(dv) \right].
\]

With the same argument as in the proof of Proposition 3.2, we obtain that
\[
E_{\pi}[(B, \varphi)_H \cdot g] \leq C\|\varphi\|_H \|g\|_1. \] (3.11)

On the other hand, by the integral-by-part formula for Wiener measure (see, e.g., [2, p. 208, Proposition 5.1.6]) it is easy to get
\[
E_{\pi}[(U_{\varphi} - \langle B, \varphi \rangle_H) \cdot g] = \frac{1}{2} E_{\pi}[(\varphi, Dg)_H] \leq \|\varphi\|_H \|g\|_1. \] (3.12)

Combining (3.11) and (3.12), we get the desired estimate. 

\( \square \)
We are at the position to prove Theorem 1.1. We first prove the weak convergence of \( \langle u^\varphi(t), \varphi \rangle_H / \sqrt{t} \) for fixed \( \varphi \). For \( \lambda > 0 \), consider the resolvent equation:

\[
\Lambda f_{\lambda, \varphi} - \mathcal{K} f_{\lambda, \varphi} = U_{\varphi}, \tag{3.13}
\]

Define the Dynkin’s martingale corresponding to \( f_{\lambda, \varphi} \in \text{dom}(\mathcal{K}) \) as

\[
M_{\lambda, \varphi}(t) = f_{\lambda, \varphi}(\xi_t) - f_{\lambda, \varphi}(\xi_0) - \int_0^t \mathcal{K} f_{\lambda, \varphi}(\xi_r) dr.
\]

\( M_{\lambda, \varphi}(t) \) is a square integrable martingale. Due to the arguments in [9, Theorem 2.14, Sects. 2.7, 9.5], with Proposition 3.2 we can obtain that

\[
\lim_{\lambda \downarrow 0} \mathbb{E}^\pi \left[ \sup_{0 \leq t \leq T} \left| M_{\lambda, \varphi}(t) - \int_0^t \langle D f_{\varphi}(\xi_r), dW_r \rangle_H \right|^2 \right] = 0, \ \forall T > 0, \tag{3.14}
\]

where \( f_{\varphi} = \mathcal{H}_1 \cdot \lambda \downarrow 0 f_{\lambda, \varphi} \). Furthermore, by [9, p. 51, Lemma 2.10],

\[
\lim_{t \to \infty} \lim_{\lambda \downarrow 0} \mathbb{E}^\pi \left[ \frac{1}{t} \left| \int_0^t U_{\varphi}(\xi_r) dr - M_{\lambda, \varphi}(t) \right|^2 \right] = 0. \tag{3.15}
\]

Combining (3.3), (3.14) and (3.15) together, we get

\[
\lim_{t \to \infty} \mathbb{E}^\pi \left[ \frac{1}{t} \left| \langle u^{\varphi, t}(t), \varphi \rangle_H - \int_0^t \langle D f_{\varphi}(\xi_r) + \varphi, dW_r \rangle_H \right|^2 \right] = 0.
\]

Notice that \( \pi \) is ergodic, by central limit theorem for martingales (see, e.g., [9, p. 36, Theorem 2.1]), for all bounded continuous function \( f \) on \( \mathbb{R} \),

\[
\lim_{t \to \infty} \mathbb{E}^\pi \left[ f(\frac{\langle u(t), \varphi \rangle_H}{\sqrt{t}}) - \int \frac{f(y)}{\sqrt{t}} \Phi_{a^2}(\varphi) dy \right] = 0, \tag{3.16}
\]

where \( \Phi_{a^2}(\varphi) \) stands for the probability density function of Gaussian distribution with mean 0 and covariance \( a^2(\varphi) = E_{\pi} \| D f_{\varphi} + \varphi \|^2_H \).

Next, to prove (1.6), it suffices to verify that \( a(\varphi) = 0 \) for all \( \varphi \) orthogonal to the constant function \( 1 \). Consider the function \( g_{\varphi}(\xi) \triangleq -\langle \nu_{\xi}, \varphi \rangle_H \) for such \( \varphi \). Noting that \( g_{\varphi} \) is well defined and solves the cell problem \( -\mathcal{K} g_{\varphi} = U_{\varphi} \), hence \( g_{\varphi} = f_{\varphi} \) in (3.14). Consequently, \( a^2(\varphi) = E_{\pi} \| D g_{\varphi} + \varphi \|^2_H = 0 \) and thus (1.6) holds with

\[
a^2 = a^2(1) = \lim_{\lambda \downarrow 0} E_{\pi} \| D f_{\lambda, 1} + 1 \|^2_H, \tag{3.17}
\]

where \( f_{\lambda, 1} \) is the solution to (3.13) when \( \varphi = 1 \).

We are left to show that \( a^2 \in [C, 1] \) for some \( C > 0 \) depending only on \( V \). To this end, we introduce two scalar products for \( H \)-valued functions on \( \Xi \) (cf. [9, Sect. 2.2]). Consider \( F, G : \Xi \to H \). Let \( \langle F, G \rangle_H = E_{\pi} \|\langle F, G \rangle_H \| \), and

\[
\langle F, G \rangle_H = E_Q \left[ \int_{\Xi} \langle F(\tau_{\nu(\xi)}), G(\tau_{\nu(\xi)}) \rangle_H \mu_0(d\nu_\xi) \right].
\]
Furthermore, define the norm $\|F\|^2 = \langle F, F \rangle$ and denote by $L^2(\Xi, H)$ the Hilbert space consisting of all functions with finite $\|\cdot\|$ norm, equipped with the inner product $\langle \cdot, \cdot \rangle$. Define $\|\cdot\|_\pi$ and $L^2(H^\pi)$ similarly.

From (3.13) we know $\langle \lambda f_{\lambda, \varphi} - K f_{\lambda, \varphi} - U \varphi, f_{\lambda, \varphi} \rangle = 0$, which implies that

$$
\lambda \|f_{\lambda, \varphi}\|^2_\pi + \frac{1}{2} \|Df_{\lambda, \varphi}\|^2_\pi + \frac{1}{2} \langle \varphi, Df_{\lambda, \varphi} \rangle = 0.
$$

Let $\lambda \downarrow 0$, we have $\langle Df_\varphi + \varphi, Df_\varphi \rangle = 0$, so that $Df_\varphi + \varphi$ and $-Df_\varphi$ are orthogonal to each other in $L^2(H)$. Taking $\varphi = 1$, it easily follows from the orthogonality that

$$
a^2 = E_\pi \|Df_\varphi + \varphi\|^2_H \leq E_\pi \|Df_\varphi + \varphi - Df_\varphi\|^2_H = 1.
$$

On the other hand, since $Q$ is $\{\tau_c\}$-invariant, for all $f \in E(\Xi)$ we have

$$
\langle \mathbf{1}, Df \rangle = \int_\Sigma \int_{E_0} \left[ \frac{d}{dc} f^{r_c}(v) \right]_{c=0} \mu_0(dv) Q(d\sigma) = 0.
$$

Since $E(\Xi)$ is dense in $H_{1,1}$, $\mathbf{1}$ is orthogonal to the subspace $H_g \equiv \{Df; f \in H_{1,1} \}$ under the inner product $\langle \cdot, \cdot \rangle$. Therefore, with $C = Z^{-1} \exp(-2\sup|V|)$ we have

$$
a^2 \geq \min_{f \in H_{1,1}} \|Df \mp 1\|_H^2 \geq C \min_{f \in H_{1,1}} \|Df \mp 1\|_H^2 = C.
$$

The proof of Theorem 1.1 is then completed.

**Remark 3.4.** In the symmetric case $B = 0$, we can prove the following variational formula (cf. [9, p. 335, Theorem 10.5]) for the limiting variance $a^2(\varphi)$:

$$
a^2(\varphi) = \min_{f \in H_{1,1}} \|Df + \varphi\|^2_\pi.
$$

Indeed, let $B = 0$ and write (3.13) in the weak form for $g \in E(H)$,

$$
\lambda \langle f_{\lambda, \varphi}, g \rangle_\pi + \frac{1}{2} \langle Df_{\lambda, \varphi} + \varphi, Dg \rangle_\pi = 0.
$$

Let $\lambda \downarrow 0$, we conclude that $Df_\varphi + \varphi$ is orthogonal to $H_g$ under the inner product $\langle \cdot, \cdot \rangle_\pi$. Hence, (3.18) is clear because that $Df_\lambda \in H_g$. In summary, the non-gradient term in (1.1') always enhances the fluctuation of the solution.
