Abstract

Mapping the central 5 pc region of the nearby radio galaxy NGC 6251 with a 0.2 pc resolution using VLBI at two radio frequencies, 5 GHz and 15 GHz, we have found the sub-pc-scale counter jet for the first time in this radio galaxy. This discovery allows us to investigate the jet acceleration based on the relativistic beaming model (Ghisellini et al. 1993).

1 Introduction

The genesis of powerful radio jets from active galactic nuclei is one of the long standing problems in astrophysics (Bridle & Perley 1984). Although global morphological properties give us very important information, very inner regions in the radio jets also provide hints to understanding the genesis of radio jets. In order to investigate radio galaxies at the sub-milli arcsecond angular resolution, we have performed new high-resolution VLBI observations of NGC 6251 using HALCA (Hirabayashi et al. 1998). We use a distance to NGC 6251, 94.4 Mpc (for a Hubble constant $H_0 = 75 \text{ km s}^{-1} \text{ Mpc}^{-1}$). Note that 1 mas (milli arcsecond) corresponds to 0.48 pc at this distance.

2 Observations

NGC 6251 was observed at 5 GHz using VSOP on 30 April 1998 and at 15 GHz using VLBA on 2 June 1998. Details of the observations are summarized in Table 1. In order to perform beam-size-matched comparison between 5 GHz and 15 GHz, we restored the two images with a same spatial resolution of $0.50 \times 0.50$ mas.
Table 1: Observations.

| Date       | ν (GHz) | Stations               | Peak Int. (Jy/beam) | RMS noise (mJy/beam) | DR |
|------------|---------|------------------------|---------------------|----------------------|----|
| 1998 Apr. 30 | 5       | VLBA, HALCA, EB²       | 0.13                | 0.50                 | 260 |
| 1998 Jun. 02 | 15      | VLBA                   | 0.34                | 0.25                 | 1400 |

¹DR : Dynamic range; ²EB : Effelsberg 100-m telescope

Figure 1: The images of NGC 6251 at 5 GHz (a) and at 15 GHz (b). The images are rotated clockwise on the sky by 28°. The spectral index map is also shown (c). Here the spectral index α is defined as $S_\nu \propto \nu^\alpha$.

3 Results

Our final maps at 5 GHz and 15 GHz are shown in Figure 1a and 1b, respectively. Although the secondary peak is seen at both frequencies, its angular distance from the 15 GHz brightest peak is larger by 0.3 mas (0.14 pc) than that at 5 GHz. This difference may be attributed to the different opacity toward the central engine at 5 GHz and 15 GHz.

Here we apply two new methods for the registration using correlation functions between intensity profiles and between wiggling patterns of the radio jet at the two frequencies. The correlation function of intensity profiles exhibits the maximum correlation coefficient $\approx 0.98$ at an offset of $0.30 \pm 0.11$ mas, indicating that the peak at 5 GHz is shifted to the jet direction from that at 15 GHz. Analysis of wiggling patterns gives an offset of $0.60 \pm 0.36$ mas with a correlation coefficient of $\approx 0.66$. Since these two offsets were obtained using the two independent methods, we adopt a weighted average of the two offsets. Thus the best offset of $0.42 \pm 0.14$ mas is obtained. Using this offset, we register the two images and obtain a spectral index image of the radio jet as shown in Figure 1c. It can be seen optically thin component in the opposite side of the jet. We conclude that this is the real counter jet.
4 Discussions

We assume for simplicity that the core is surrounded by a plasma sphere with a radius of $a$ and the radio emission from the inner part of the jets (i.e., both the jet and the counter jet) suffer from the free-free absorption. The approaching jet escapes from the plasma sphere at a projected distance of $x = a \times \sin \theta_{\text{jet}}$ and thus the spectral index becomes to be intrinsic here. The counter jet suffers the effect of free-free absorption until $x = -a$. It is also noted that the path length is longest at $x = -a \times \sin \theta_{\text{jet}}$. As shown in Figure 2a, we define the following projected distances; $X_{\text{jet}} = X_{\text{peak}} = a \times \sin \theta_{\text{jet}}$ and $X_{\text{cjet}} = a$. Then we are able to estimate $\theta_{\text{jet}} = \sin^{-1} \left( \frac{X_{\text{jet}}}{X_{\text{cjet}}} \right)$. We adopt the 15 GHz brightest peak as the core, because the optical depth at 15 GHz is enough to be small in the case of free-free absorption. In Figure 2b, we show the observed spectral index variation along the radio jet. We estimate $X_{\text{peak}} \approx 0.24$ mas, $X_{\text{jet}} \approx 0.41$ mas, and $X_{\text{cjet}} \approx 0.80$ mas. Then we obtain $\theta_{\text{jet}} \simeq 31^\circ$.

Adopting the so-called Doppler beaming model, the jet to the counter jet intensity ratio $R$ can be written as a function of projected distance $x$,

$$R(x) = \left[ \frac{1 + \beta_{\text{jet}}(x) \cos \theta_{\text{jet}}(x)}{1 - \beta_{\text{jet}}(x) \cos \theta_{\text{jet}}(x)} \right]^{2 - \alpha(x)} ,$$

where $\beta_{\text{jet}}(x) = v_{\text{jet}}(x)/c$. In Figure 3a, we measured $R$ as a function of $x$. It is shown that $R$ is estimated...
Figure 3: The jet/counter jet flux density ratio $R$ as a function of the projected distance from the brightest peak at 15 GHz for the 5GHz data (filled triangle) and for the 15 GHz data (filled circles) (a), and jet velocity $\beta_{\text{jet}}$ as a function of projected distance from the brightest peak at 15 GHz (b).

to be systematically larger at 5 GHz than those at 15 GHz. This is probably due to stronger absorption at 5 GHz than at 15 GHz. It is shown that $R$ at 15 GHz increases from 1.7 at 0.85 mas (0.4 pc) to 10 at 1.25 mas (0.6 pc) with projected distance from the core. If this increase is just caused by the Doppler beaming, it is suggested that $\beta_{\text{jet}}$ increase with distance, because it cannot be seen that $\theta_{\text{jet}}$ varies significantly. Figure 3b shows that the jet is accelerated from $\beta_{\text{jet}} \approx 0.1$ at 0.4 pc to $\beta_{\text{jet}} \approx 0.5$ at 0.6 pc. This provides the first direct evidence for the acceleration at the sub-pc-scale radio jet.

Acknowledgements. We gratefully acknowledge many staff members of VLBA and VSOP who operated observations without whom this study would not have been possible.
