The German HNPCC consortium: aims, structure, methods and data

C. Engel¹, S. Aretz²

¹Institute for Medical Informatics, Statistics and Epidemiology, University of Leipzig, Leipzig, Germany; ²Institute of Human Genetics, Center for Hereditary Tumor Syndromes, Biomedical Center, University Hospital Bonn, Bonn, Germany

*Hereditary Cancer in Clinical Practice* 2019, **17**(Suppl 2):N1

**Correspondence:** C. Engel

**Aim**
The German HNPCC Consortium, founded in 1999, is a joint network of currently 14 clinical university centers, a reference pathology, and a central documentation facility aiming to provide structured interdisciplinary care and research for individuals suspected of having an inherited predisposition for colorectal cancer. In the past, the consortium has focused on Lynch Syndrome (LS) but aims to cover also the broad spectrum of other familial colorectal cancer entities.

**Method**
Families are ascertained based on the established Amsterdam and Bethesda criteria. Interdisciplinary care comprises genetic counseling, molecular pathological tumour analyses for mismatch repair deficiency, germline testing of predisposing genes, and structured intensified surveillance measures. Research goals are e.g. search for new disease causing genes, genotype-phenotype correlations and tumour risks, tumour immunology, and efficacy of intensified surveillance.

**Results**
The consortium has established a central research database, which is populated by the clinical centres using a web-based remote online data capture application based on standardized documentation. The scope of the retro- and prospective data collection comprises fully structured pedigrees, familial tumour history, detailed results of diagnostics and results of surveillance.

**Conclusion**
Currently, approx. 8,800 individuals (patients, asymptomatic mutation carriers, relatives at risk) from 5,500 families are centrally registered (2,100 LS patients).

**Acknowledgements**
On behalf of the German HNPCC Consortium

Prevalence, phenotype and clinical consequences of mosaicism in APC and other colorectal cancer and polyposis associated genes

M. Suerink¹, S. Aretz²,³, A. Wagner⁴, M. Nielsen¹, T. van Wezel⁵, H. Morreau⁵

¹Department of clinical genetics, LUMC, Leiden, The Netherlands; ²Institute of Human Genetics, University of Bonn, 53127 Bonn, Germany; ³Center for Hereditary Tumor Syndromes, University of Bonn, 53127 Bonn, Germany; ⁴Department of clinical genetics, Erasmuc Medical Centre, Rotterdam, The Netherlands; ⁵Department of pathology, LUMC, Leiden, The Netherlands

*Hereditary Cancer in Clinical Practice* 2019, **17**(Suppl 2):N3

**Correspondence:** M. Suerink

**Aim**
APC mosaicism is identified in ~25% of previously unexplained polyposis patients with >20 adenomas. Prevalence of APC mosaicism in more mildly affected polyposis patients is currently unknown. Furthermore, surveillance advice is now the same for germline and mosaic APC patients, while a milder phenotype in the latter is expected. In the LUMC in Leiden, The Netherlands, a new study will start this year examining the prevalence of APC mosaic mutations in mildly affected polyposis patients as defined below. All mosaic patients will be recorded meticulously to determine phenotype.

**Method**
FFPE material of colorectal neoplasms (adenomas and/or colorectal cancers) of patients meeting the following criteria will be collected:

- >5 adenomas and aged <50
- >10 adenomas and aged <70y
- >20 adenomas and aged >70y
- meta- or synchronous CRC <70y
- 10-20 adenomas, between ages 55-75y, identified by population-based screening

We expect inclusion to start in the second half of 2018. DNA will be isolated from the neoplasms (n≥2) and a gene panel (including the following genes: APC, POLE/D1, MUTYH, NTHL1, MSH3, MLH1, MSH2, MSH6, PMS2, SMAD4, BMPR1A, ENG, RNF43, STK11, TP53, BRCA1, BRCA2, PALB2 and PTEN) will be run to identify APC mosaic cases as well as other (mosaic) causes of polyposis/colorectal cancer. Identification of the same mutation in multiple samples of the same patient will be considered to be indicative of mosaicism. Whenever possible,
DNA isolated from leucocytes, buccal mucosa and urine will then be analyzed to see whether the variant can be identified in these tissues as well. Eligible patients will need to provide written consent before they are included.

Results
The main outcome will be prevalence of mosaic mutations in the above mentioned patient groups. Furthermore, mutation patterns and clinical phenotype will be recorded to study the mechanisms behind mosaicism and provide data to adapt surveillance guidelines.

Conclusion
A new study is starting this year at the LUMC in Leiden with the aim of further clarifying the prevalence, phenotype and clinical consequences of APC mosaicism. We invite attendees of the EHTG who have several cases that meet the selection criteria to contact us to discuss participation. We require tissue from multiple tumors from well described cases and can accommodate the NGS gene panel.

Division of Evolution and Genomic Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, UK; Prevention Breast Cancer Unit and Nightingale Breast Screening Centre, Manchester University NHS Foundation Trust (South), Manchester, UK; Division of Informatics, Imaging and Data Sciences, School of Health Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, UK; Manchester Academic Health Science Centre, University of Manchester, Manchester, UK; Centre for Cancer Prevention, Wolfson Institute of Preventive Medicine, Charterhouse Square, Barts and The London, Queen Mary University of London, London, UK; The Christie NHS Foundation Trust, Manchester, UK; Manchester Centre for Genomic Medicine, Manchester University NHS Foundation Trust (Central), Manchester, UK; Manchester Breast Centre, Manchester Cancer Research Centre, University of Manchester, Manchester, UK
Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N4

Correspondence: D. G. Evans
Aim
To better stratify breast cancer risks to enable more targeted early detection/prevention strategies particularly to balance the risks/benefits of population.

Method
Data from 9,362 women unaffected by breast cancer at study entry who provided a DNA sample for polygenic-risk-score (PRS) were analysed from the 57,902 women in the PROCAS study. The PRS score was analysed along with mammographic density (density residual-DR) and standard risk factors to assess future risk of breast cancer pathological type and hormonal receptor status.

Results
For the 195 prospective breast cancers a predictor based on Tyrer-Cuzick/DR/PRS was informative for subsequent cancer overall and more so for stage 2+ cancers and calibrated (0.99) for predicting cancers across all risk groups. Although DR was most predictive for HER2+ and stage 2+ cancers it did not discriminate as well between poor prognosis cancers and extremely good prognosis cancers as Tyrer-Cuzick or the PRS, with the PRS providing the highest OR for post-prevalent stage 2+ cancers (OR=1.79 (95%CI:1.30-2.46).

Conclusion
A combined approach using Tyrer-Cuzick, mammographic density and a PRS provides accurate risk stratification not only overall but also for worse prognosis cancers. This provides support for reducing screening intervals in the high and increasing them in the low risk groups.

N5
Exogenous and endogenous associated factors to early onset colorectal cancer

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N5

Correspondence: R. Zuppardo
Aim
Early onset colorectal cancers (eoCRC < 50 years), is projected to increase by as much as 90% and 140%, respectively by 2030, and germline mutations appear to account for only about 20%. We investigate the role of exogenous and endogenous risk factors as associated factors in eoCRCs.

Method
Clinical, anamnestic and pathological data were retrieved on eoCRC patients from 08/2017 to 04/2018, and compared with a group of late onset CRC (loCRC) of the same period.

Results
We enrolled 33 eoCRCs and 48 loCRCs, mean age 40.7 +/- 7.3 and 66.1 +/- 9.8, respectively (p<0.001), prevalence of females (54.5% in eoCRCs and 52.1% in loCRCs). Diagnostic delay was higher in eoCRC group: 42.4% of eoCRCs diagnosed in the 6th months from symptoms onset versus 100% of loCRC patients (p<0.001). Lynch syndrome was more frequent in eoCRC (12%) than loCRC group (0%) p=0.02. A statistically significant difference was found in alcohol habit, 66.7% of no-drinker in eoCRCs and 41.7% of loCRCs (p=0.04), and a trend through significance for no-smokers in eoCRCs.

Conclusion
CRC should be considered earlier for differential diagnosis in young patients. We confirmed alcohol as cofactor in development of eoCRC and we underlined that familiar history should be collected to identify mutations carriers.

N7
Cancer risks by age and gender and survival after cancer in path_MSH6 carriers: a Prospective Lynch Syndrome Database (PLSD) report

Correspondence: J. Sampson
Aim
To determine cancer risks by age and gender and cancer survival in carriers of path_MSH6 variants.

Method
An independent cohort of class 4 or 5 path_MSH6 carriers was used to validate findings reported previously by PLSD. Data for individuals in the previous and validation cohorts who carried class 4 or 5 variants listed in the InSiGHT variant database were then combined and
analysed by age and gender, deriving more precise risk and survival estimates to inform management.

Results
The validation cohort (N=425) provided 2,367 prospective observation years and confirmed previously reported cumulative risks for any cancer: 14% vs 18% at fifty years and 48% vs 53% at 70 years. The combined series of 841 carriers of 4/5 path_MSH6 variants provided 5,205 prospective observation years. Cumulative risks at 75 years in males/females were: any cancer 42%/60%; colorectum 18%/20%; endometrium NA/41%; ovary NA/11%; stomach, duodenum, bileduct, pancreas 8%/4%; ureter, kidney 2%/6%; bladder 8%/1%; prostate 9%/NA; breast NA/14%; brain 2%/1%. Ten-year crude survival following cancer was: colon 100%; rectum 86% and endometrium 90%. See www.PLSD.eu to calculate risks for individual patients by age and gender.

Conclusion
MSH6-associated Lynch syndrome has distinct characteristics with a high risk of endometrial cancer compared to other organs.

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N09

Correspondence: M. Jenkins

Aim
The International Mismatch Repair Consortium (IMRC) was established to determine cancer risks by geographic region.

Method
Pedigree data for 6,436 Lynch syndrome families from 22 countries were submitted by researchers/clinicians throughout the world to the analysis team at the University of Melbourne. We estimated the cumulative risks (penetrance) by geographic region. We used a modified segregation analysis and adjusted for any ascertainment of families.

Results
Preliminary analysis suggest that for MLH1 mutations, the risk of colorectal cancer to age 70 is highest for carriers in Australia (68% males, 55% females) and North America (61% males, 48% females) and lowest for carriers in South America (12% males, 10% females) and East Asia (20% males, 14% females). For MSH2, the patterns were similar, except for South America which had a high estimated average risk (82% males, 75% females).

Conclusion
Collection of MMR family data from many international sites has progressed well despite the challenges faces by sites to establish databases for epidemiological research with varying resources. Preliminary results suggest that cancer risks for people with Lynch syndrome differ by geographic region which is consistent with environmental modifiers for the disease and might justify region specific screening guidelines.

Aim
NF1 predisposes to breast cancer (BC), but no genotype-phenotype correlations have been described.

Method
Constitutional NF1 mutations in 78 NF1 patients with BC (NF1-BC) were compared to the NF1 LOVD (N=3432).

Results
There are no gross relationships with mutation position. No correlations have been described.

Conclusion
This demonstrates that certain heritable mutation types, and indeed certain specific mutations in NF1 confer different risks of BC. The observation that NF1 amplification does not always occur with, and can occur independently of ERBB2 amplification, supports the concept that BC risk in NF1 may be due to gain of function mutations. A prospective NF1-BC study needs to be established. Regardless of NF1 mutation status NF1-BC patients warrant testing of other BC-predisposing genes.
A dominantly inherited 5’UTR variant causing methylation associated silencing of BRCA1 as a novel cause of breast and ovarian cancer

Correspondence: D. G. Evans

Pathogenic variants in BRCA1/BRCA2 are identified in ~20% of families with multiple individuals with early-onset breast/ovarian cancer. Extensive searches for additional highly penetrant genes/alternative mutational mechanisms altering BRCA1/2 have not explained the missing heritability. For the first time, we report a dominantly inherited 5’UTR variant associated with epigenetic silencing of BRCA1 due to promoter hypermethylation in two families with breast/ovarian cancer.

Method

BRCA1 promoter methylation of ten CpG dinucleotides in breast/ovarian cancer families without germline BRCA1/2 pathogenic variants was assessed by pyrosequencing and clonal bisulfite sequencing. BRCA1 RNA/DNA sequencing from lymphocytes was undertaken to establish allelic expression and germline variants.

Results

BRCA1 promoter hypermethylation was identified in 2/49 families with multiple women affected with grade-3 breast/high-grade-serous ovarian cancer. Soma-wide BRCA1 promoter hypermethylation was confirmed in blood/buccal mucosa/hair follicles. Methylation levels were ~50%, consistent with complete silencing of one allele. RNA sequencing revealed allelic BRCA1 expression loss in both families segregating with a novel heterozygous variant c.-107A>T in 5’UTR.

Conclusion

Our results indicate a novel mechanism for familial breast/ovarian cancer, caused by an in cis 5’UTR variant associated with epigenetic silencing of BRCA1 promoter. We propose methylation analyses are undertaken to establish the frequency of this mechanism in families affected by early onset breast/ovarian cancer without a BRCA1/2 pathogenic variant.

Correspondence: M. Dominguez-Valentin

Aim

To study the potential contribution of genes other than BRCA1/2, PTEN, TP53 and MMR to the biological and clinical characteristics of early-onset and familial cancers in Norwegian families.

Method

The Hereditary Cancer Biobank from the Norwegian Radium Hospital was used to identify early-onset families and individuals with a high risk of developing breast, gynecological and colorectal cancers. Forty-four cancer susceptibility genes were selected and analyzed by our in-house designed TruSeq amplicon-based assay for targeted sequencing. Protein- and RNA splicing-dedicated in silico analyses were performed for all variants of unknown significance (VUS). Variants predicted as the more likely to affect splicing were experimentally analyzed by a minigene assay (PMID: 29458332, 29371908, 28608266).

Results

We analyzed 176 early onset and familial cases who harbored 5% (8/175) class 5 variants in the genes ATM (3), CHEK2 (2), MSH6, MUTYH and MAP3K1. Out of the 18 VUS tested in the minigene splicing assay, ATM c.3806A>G, NOTCH3 c.14090C>T and MSH2 c.815C>T showed a significant effect on RNA splicing.

Conclusion

Our study provides new information on genetic loci that may affect the risk of developing cancer in these patients and their families, demonstrating that genes presently not routinely tested in molecular diagnostic settings may be important for capturing cancer predisposition in these families.

Identification and characterization of an alu element insertion in BRCA2 in a Spanish family associated to prostate cancer

V. Barca-Tierno1, M. Morín1, L. Santos1, C. García-Hoz2, L. Fuente-García1, P. Marcos-Cava1, M. Salazar3, C. Guillén-Ponce1, M. A. Moreno-Pelayo1

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N14

Correspondence: V. Barca-Tierno
Aim
Pathogenic Alu element insertions are rarely reported because this type of insertions are undetectable with the classical screening methods. The aim of this work has been the identification and characterization of an Alu element insertion in a Spanish family with a history of breast/ovarian cancer.

Method
Molecular analysis was carried out using the BRCA MASTRDx (Multiplicom) and Massively Parallel Sequencing (Illumina). The Alu insertion was identified and characterized by fragments analysis, genotyping, PCR amplification and Sanger sequencing (ABI3130).

Results
We have identified and characterized a heterozygous pathogenic variant c.5007_5008ins174 located at the exon 11 of the BRCA2 gene in a patient with prostate cancer. The variant identified is a pathogenic Alu element insertion (AluYb18BRCA2) of about 174 bp long.

Conclusion
NGS has been incorporated into clinical genetic testing for hereditary cancer risk. NGS-based techniques and the standard bioinformatic pipelines, however, are unable to detect and precisely characterize ALU element insertions. In this work, we report, by using classical screening methods and bioinformatic programs, BLAST and RepeatMasked, the identification of the AluYb18BRCA2 insertion in BRCA2 coding region. This insertion could generate a frameshift resulting in the abrogation of BRCA2 protein function that has been associated with oxidative stress involved in carcinogenesis.

Correspondence: M. Terradas

Aim
The genetic defect responsible for colorectal polyposis remains unknown in much of the cases with adenomatous polyposis. Recently, MCM9 (recessive), FOCAD (recessive or dominant) and POLQ (dominant) have been identified as putatively new polyposis genes. Here we aim at providing a more definitive answer about the contribution of germline mutations in these genes to adenomatous polyposis.

Method
A total of 182 unrelated polyposis patients were screened for MCM9, FOCAD and POLQ mutations using PCR amplification in pooled DNAs combined with targeted parallel sequencing. Variants detected in the pooled samples were validated by genotyping and/or Sanger sequencing.

Results
While no homozygotes or compound heterozygotes where identified in MCM9 and FOCAD, a predicted deleterious missense variant (c.911A>G; p.N304S) was identified in heterozygosis in MCM9 in an individual with adenomatous polyposis, and 4 were identified in the FOCAD gene: c.401C>T (p.P134L), c.1393G>A (p.G465R), c.2861C>T (p.P954L) and c.3041A>G (p.Y1014C). A stop-gain variant (c.7537C>T; p.Q2513*) located in the DNA-polymerase domain and a predicted deleterious missense variant (c.4684G>T; p.D1562Y), were identified in POLQ.

Conclusion
Additional studies are currently being performed in order to elucidate the association of the identified variants with the predisposition to polyposis in the carrier families.

N19
Colorectal cancer risk is not increased in NTHL1 heterozygous mutation carriers

Correspondence: A. Ragunathan

Aim
Biallelic loss-of-function germline mutations in the base excision repair gene NTHL1 result in an increased risk of colorectal polyps and different cancer types, resulting in the inclusion of this gene on many multi-gene cancer predisposition panels. However, the impact of heterozygous germline NTHL1 mutations on colorectal cancer (CRC) risk is unclear.

Method
1953 CRC-affected individuals and 1207 controls from the Colon Cancer Family Registry Cohort were screened for coding single nucleotide and short indels variants in NTHL1 using a targeted multiplex PCR-based sequencing approach (Hi-PLEX). Variants were filtered on sequencing depth and allele proportions. Variants were predicted to be pathogenic if they were novel or rare (gnomAD < 0.05%), protein truncating variants or missense variants predicted to be deleterious (based on CADD>20 or REVEL>0.5).

Results
We detected 22 (1.13%) predicted pathogenic variants in cases and 17 (1.41%) in controls (OR=0.79, 95% CI=0.42-1.48, p=0.51), all carriers were heterozygotes. The loss-of-function variants identified were not different in frequency between CRC cases (n=5, 0.26%) and controls (n=5, 0.41%; OR=0.62, 95%CI=0.18-2.14, p=0.52), and of similar frequency to rare NTHL1 loss-of-function variants observed in gnomAD (0.199%).

Conclusion
The effect of heterozygous NTHL1 predicted pathogenic variants on CRC risk, if any, is not likely to be more than 1.5 fold.

N22
Family case of rare MSH6 variant identified as secondary finding - shall we screen for Lynch?
Tomas Szemere1, 2, 3
1Genoton Ltd., Bratislava, Slovak Republic; 2Comenius University School Park, Bratislava, Slovak Republic; 3Faculty of Natural Sciences, Bratislava, Slovak Republic

Correspondence: Tomas Szemere

Aim
In Slovakia, the incidence of colorectal cancer is one of the highest worldwide and could be a result of higher incidence of cancer predisposing syndromes, such as Lynch syndrome. Novel large gene panel, exome or whole genome tests become less costly and widely available which allow detection of cancer predisposing genetic variants. In addition, novel non-invasive methods for tumor screening (liquid biopsy) become available as well.

Method
A clinical exome test was carried out in 20yo male. Identification of variants relevant for secondary findings was carried out too. Identified variants were verified by Sanger sequencing. A family follow-up included clinical exome test as well as Sanger confirming tests. Written informed consent to publish was obtained from the patients involved in this study.
Results
We identified a rare potentially pathogenic variant in MSH6 gene in 20yo male as secondary finding. In addition a rare BRCA2 variant was also detected and confirmed. Despite family cancer history did not meet used criteria it was tested for these variants. A suspected case of metastatic breast cancer in the family was confirmed in 65yo female bearing the in 12/2017 and a suspected case of CRC was identified in 67yo male bearing the MSH6 variant. All family members adhered to required medical procedures after genetic testing.

Conclusion
Genomic tests and their wider availability with novel liquid biopsy methods offer novel cancer screening algorithm options. A case of family with two detected variants in both BRCA2 and MSH6 a secondary finding shows possible benefits but social aspects have to be considered for wider implementation.

Systematic linkage of all diagnostic hereditary cancer genotypes to the National Cancer Registry
F. McDonald, B. Shand, N. Briquet, S. Vernon, J. Rashbass, J. Burn
Public Health England, UK; Health Data Insight CIc, Cambridge, UK; Northern Genetics Service, Newcastle, UK
Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N24

Correspondence: F. McDonald

Aim
To create a national service collecting pseudonymised germline cancer-predisposing genotypes, and link these to the National Cancer Registration and Analysis Service for individuals with a prior or subsequent cancer diagnosis.

Method
NHS molecular genetics laboratories submit patient-level genotype data through a secure online portal. Unique patient demographics are pseudonymised using a one-way hash function that generates an irreversible pseudID; additional identifiers are secondarily encrypted. The same hash function applied to cancer registration records, where patient identity is already known, enables linkage of the genotype data; decryption of additional identifiers is then possible. We can thus obtain accurate variant counts nationally, and identify those who develop cancer, without compromising patient privacy.

Results
Pilot work has focused upon BRCA1 and BRCA2 genes; we are now commencing collection of colorectal cancer predisposition gene data. To date, ten laboratories have submitted BRCA1/2 data, covering a time period from 2001 onwards, and including ~1300 different gene variants. Initial linkage to cancer registry records showed a 68% match rate.

Conclusion
This robust, secure system collects depersonalised but linkable genotypes on all individuals tested. Record-level linkage to the rich phenotype, treatment and outcome data in the national cancer registry provides allelic frequency and associated phenotype data, and facilitates variant interpretation.

Life-long immune surveillance and immunoediting – evidence From Lynch syndrome cancers
M. Kloor1, M. Ozcan1, J. Janikovits2, F. Echterdiek3, A. Ahadova4, J. Krysykalla1, A. Bennet1, M. von Knebel Doeberitz1* 1Department of Applied Tumor Biology, University Hospital Heidelberg; 2German Cancer Center Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N30

Correspondence: M. Kloor
Aim
Lynch syndrome-associated cancers accumulate a high load of immunogenic frameshift peptide neoantigens as a consequence of DNA mismatch repair (MMR) deficiency. MMR-deficient cells can therefore be recognized by the immune system. We aimed to comprehensively characterize the immune phenotype of MSI cancers, accounting for somatic mutations inducing immune evasion and for immune cell infiltration.

Method
We combined the analysis of our own cohort of MSI cancers with mutation data of MSI cancers of the TCGA/DFCI cancer collections. Immune cell infiltration was quantified by immunohistochemistry, using antibodies specific for T cell subtypes, including CD3, FOXP3, and PD-1.

Results
72% of MMR-deficient colorectal cancers of the DFCI database harbored alterations affecting genes involved in HLA class I-mediated antigen presentation. The most common alterations were truncating mutations affecting the Beta2-microglobulin (B2M) gene. B2M mutations were related to a higher density of activated T cells infiltrating the tumor, and to a lower frequency of regulatory T cells in the tumor environment.

Conclusion
The extraordinarily high prevalence of immune evasion phenomena in MSI cancer most likely reflects life-long immune surveillance and suggests that most MSI pre-cancers are eliminated by the immune system if they fail to evade the immune attack.

N32
A novel mainstreaming model for Lynch syndrome genetic testing in colorectal cancer patients
D. Georgiou1, B. Desouza2, A. F. Brady1, N. Ellery1, C. Berlin1, A. Latchford3, S. Clark4, H. J. Thomas5* 1North West Thames Regional Genetics Service; 2South East Thames Regional Genetics Service; 3Polyposis Registry, St Marks Hospital; 4Family Cancer Clinic, St Marks Hospital Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N32

Correspondence: D. Georgiou
Aim
New NICE guidance (2017) recommends universal tumour screening for Lynch syndrome (LS) in all patients with newly diagnosed colorectal cancer (CRC). Identifying CRCs with deficient DNA mismatch repair (dMMR) will guide further diagnostic testing for LS. Establishing a diagnosis of LS signifies that most patients with suspected LS should have access to appropriate diagnostic testing performed within a suitable time frame. Based on the anticipated rapid increase in clinical need, we have developed and implemented a novel mainstreaming model for LS genetic testing.

Method
Reflex IHC testing is undertaken in all newly diagnosed CRC cases; abnormal results are reviewed at the colorectal MDM, and eligible patients offered germline testing at their routine cancer appointments by appropriately trained cancer clinicians (i.e. oncologists and surgeons). Genetic results are fed back to patients by the cancer team, and all patients with a pathogenic variant or a variant of unknown significance are referred to clinical genetics for further management.

Results
We present the pathway as adopted at St Marks Hospital and the outcomes from the first year post implementation.

Conclusion
This pathway was effective at our hospital.

N33
Validation and updating of Path_MLH1 in cases with class 4 and 5 genetic variants: a Prospective Lynch Syndrome Database (PLSD) Report

Correspondence: T. Seppälä
Aim
Determine average risks for and survival after cancer in path_MLH1 carriers.

Method
Previously reported results were validated in an independent series of path_MLH1 carriers followed-up by colonoscopy. Combined results merging former and present series included only carriers with pathogenic class 4 or 5 variants listed in the InSiGHT database.

Results
The validation series including 10,037 observation years confirmed previously published cumulative risk for any cancer: at fifty years, 37% in the validation series compared to 40% in the previous series, and at 75 years, 78% compared to 76%. The combined series of path_MLH1 variant carriers included 24,297 observation years. Cumulative risk for cancer in specific organs or group of organs at 75 years were (males/females): Any cancer 70%/80%; colon_rectum 56%/47%; endometrium -/73%; ovaries -/11%; stomach_duodenum_bileduct_pancreas 21%/11%; ureter_kidney 4%/3%; urinary bladder 64%/ 4.9%; prostate 12%/1%; breast -/2%; brain 0.7%/1.6%. Ten-year crude survival after cancer in different organs were: colon 86%; endometrium 90%; ovaries 82%; ureter_kidney 61%; urinary bladder 54%; prostate 90%; breast 80%; brain 0%.

Conclusion
PLSD reports average risks for and survival after cancer in path_MLH1 carriers of variants classified as clinically actionable in the InSiGHT database. See www.PLSD.eu for risk determination in any single patient by age and gender.

An assessment of endometrial cancer risk markers in Lynch syndrome patients
A. Alonso1, R. Guarch1, S. Moreno1, E. Recari1, M. Miranda1, I. Chirivella2, E. Lstra2, L. Robles3 1Complejo Hospitalario Navarra, Spain; 2Hospital Clínico Universitario de Valencia, Spain; 3Hospital Universitario de Burgos, Spain; 4Universitario 12 Octubre Madrid, Spain Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N34

Correspondence: A. Alonso
Aim
Assessment of a set of markers to anticipate endometrial cancer occurrence in healthy female Lynch syndrome (LS) carriers.

Method
Materials: 242 biopsy specimens obtained during the prospective annual follow-up of 79 Lynch syndrome (LS) carriers from 4 different Spanish Centers.
Investigated markers were (High Microsatellite Instability MSI-H: abnormal mismatch repair proteins (MMR-ICHC) or PTEN (PTEN-ICHC) immunohistochemistry; LINE sequences (LINE-CIN) or MMR genes CpG islands abnormal methylation (MMR-MMR), and somatic mutations in a custom panel of 27 genes related to type 1 endometrial carcinogenesis (Panel-27).

Results
Simultaneous presence of abnormal MMR and PTEN-ICHC anticipated the occurrence of the precursor lesion “focal hyperplasia” in a median time of 19.63 months (CI95=17.55-21.71) with a Hazard Ratio HR= 3.97 (CI95=1.32-11.9) vs the no markers group. Panel-27 somatic mutations rate was also higher (75x10-6 mutations per Mb vs. 12x10-6 mutation per Mb, p<0.00) in these samples.

Conclusion
These findings provide a basis for recommending to introduce the investigation of these markers in biopsy specimens from LS patients, as a supportive tool for selecting the most appropriate management option in these patients (prophylactic hysterectomy vs surveillance)

N36
Back to back comparison of colonoscopy with virtual chromoendoscopy using third generation narrow band imaging system to chromoendoscopy with indigo carmine in Lynch syndrome patients

E. Samaha1, C. Colas3, M. Dhooge3, J. C. Saurin4, T. Lecomte5, E. Coron6, G. Rahimi6, G. Perrodi7, C. Savale7, S. Chaussade7, J. Bellanger7, N. Bench8, J. P. Barbiez5, M. Le Rhun9, H. Pereira10, G. Chatellier10, C. Cellier10, E. European Georges Pompidou Hospital; 2Saint Antoine Hospital; 3Cochin Hospital; 4Edouard Heriot Hospital; 5CHU Tours; 6CHU Nantes

Correspondence: E. Samaha

Aim
Colonoscopic screening with indigo carmine chromoendoscopy (ICC) in Lynch Syndrome (LS) patients improves adenoma detection rate and is widely used nowadays. Nevertheless, it is a time- and-money-consuming technique which requires a dedicated training. Narrow band imaging (NBI) is a well-known virtual chromoendoscopy technique that highlights superficial mucosal vessels and improves contrast for adenomas. We conducted a prospective multicenter study in a back-to-back fashion to compare 3rd generation NBI to ICC for detecting colonic adenomas in LS patients.

Method
One hundred and thirty eight patients underwent a double colonoscopy, first with NBI, followed by ICC, in a back-to-back fashion. All polyps detected in either pass were removed for histopathological analysis. The primary outcome measure was the number of patients with at least one adenoma after NBI compared with the number of patients with at least one adenoma after NBI and ICC. Proportions were compared with the paired exact test (McNemar’s test). Continuum variables were compared with the Wilcoxon signed-rank test.

Results
All of the 138 patients were proven MMR mutation carriers (MLH1 = 33%, MSH2 = 47%, MSH6 = 15%, PMS2 = 4%, EPcam = 1%). Mean age (standard deviation [SD]) was 40.5 (14.7) years, 64 (46.4%) were male. The median time for an NBI procedure was 8 minutes (interquartile range [IQR] 6–11) compared to 13 minutes (IQR 8–17) for ICC. At least one adenoma was detected during the initial NBI pass in 28 (20.3%) of 138 patients. ICC detected additional adenomas in 25 (18.1%) of 138 patients. Forty-two patients (30.4%) had at least one adenoma detected after both NBI and ICC; this represents an increase of 50.0% of the adenoma detection rate (ADR) (p=0.0001). The total number of adenomas increased from 39 after NBI pass to 75 after ICC pass with a mean number of adenomas detected per patient of 0.3 (0.7) after NBI pass vs 0.5 (1.1) after both NBI and ICC passes (p<0.0001). The ADR for flat adenomas was 10.9% after NBI vs 23.2% after ICC (p=0.0001). The ADR increased for right sided adenomas (10.9% after NBI vs 16.7% after ICC, p<0.0001). Detection of both sessile adenomas (11.6% NBI vs 13.8% ICC, p=0.25) and adenomas > 5mm (6.5% NBI vs 8.0% ICC, p=0.50) did not differ significantly between the 2 techniques. After adding white light detected adenomas, the total ADR of the study was 33.3%.

Conclusion
Colonoscopy with indigo carmine chromoendoscopy detects significantly more adenomas than 3rd generation NBI in LS patients, whereas sessile and > 5mm adenomas are equally detected. Although less time consuming, NBI colonoscopy cannot be recommended to replace indigo carmine chromoendoscopy in LS patients.

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N37

Correspondence: M. Domínguez-Valentin

Aim
Determine average risks for cancer in path_PMS2 carriers.

Method
Prospectively observed cancers in carriers of PMS2 variants classified as pathogenic (class 4/5) in the InSiGHT database.

Results
407 carriers were prospectively observed for 2239 years and they underwent regular surveillance and if needed polypectomies. Cumulative incidences for cancer at 50/75 years of age were: Any cancer 8% (95% CI 0%-19%); colorectal 0% (95% CI 0%-9%); endometrial 0% (95% CI 0%-21%); ovarian 0% (95% CI 0%-9%); and urinary tract 0% (95% CI 0%-9%) cancer.

Conclusion
Neither colorectal, endometrial, ovarian nor urinary tract cancer was observed before 50 years of age. The point estimates for colorectal and endometrial cancers at age 75 were, however, higher than expected despite undergoing regular surveillance. The patients examined were mostly selected from cancer kindreds, and the late onset cancers might not necessarily have been caused by the path_PMS2 variants. Clinical guidelines for monoplethic path_PMS2 carriers should be revised.

Yield of Lynch syndrome surveillance for individual MMR genes

A. Goverde1, A. Wagner1, E. Viskii1, M. J. Bruno2, R. M. W. Hofstra1, M. C. W. Spaander2

1Department of Clinical Genetics. Erasmus MC, University Medical Center, Rotterdam, The Netherlands; 2Department of Gastroenterology and Hepatology, Erasmus MC, University Medical Center, Rotterdam, The Netherlands

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N38

Correspondence: A. Wagner

Aim

To assess the yield of Lynch syndrome (LS) surveillance for MLH1, MSH2, MSH6 and PMS2 mutation carriers.

Method

Data on colonoscopy surveillance was collected for all LS mutation carriers in our center. We compared the development of adenomas and CRC between the different gene mutation carrier groups.

Results

Colonoscopy data was available for 264/314 (84%) patients; 55 MLH1, 44 MSH2, 143 MSH6 and 22 PMS2 mutation carriers. Median age was 44 years (IQR 35-56 years) and median follow-up time 6 years (IQR 2-10 years). At first colonoscopy CRC was found in eight patients and during 916 follow-up colonoscopies in nine patients. No CRC was found in MSH6 or PMS2 mutation carriers. There were no significant differences in the number of colonoscopies with adenomas or advanced adenomas between the different gene mutation carrier groups. In MSH6 mutation carriers advanced neoplasia (advanced adenoma or colorectal carcinoma) was found after a longer follow-up time than in the other mutation carrier groups.

Conclusion

Since no CRC was found during follow-up in MSH6 mutation carriers and advanced neoplasia was found in shorter follow-up time in MLH1 and MSH2 mutation carriers, the colonoscopy interval in MSH6 mutation carriers might be less stringent than for MLH1 and MSH2 mutation carriers.

The Prospective Lynch Syndrome Database (PLSD)

P. Møller

PI to the PLSD

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N39

Aim

Compile existing prospective data on carriers of pathogenic MMR variants.

Method

Inclusion: 1) Demonstrated monoallelic germline carriers of pathogenic variant of either of the genes MLH1, MSH2, MSH6 or PMS2 listed in the InSiGHT database. 2) Determined to be at risk for Lynch Syndrome for any reason. 3) Inclusion point: First planned and carried out prospective colonoscopy. 4) One or more follow-up years. Patient information: Age, gender, pathogenic variant, reporting centre, age and ICD9 diagnoses of all cancers (before, at or after inclusion), organs removed when. Events scored: All prospectively diagnosed cancers after inclusion by ICD9 code and age at diagnosis. Age at death. Information not yet analysed: polyps removed, stage at colorectal cancer and time since last colonoscopy. For detailed protocol see https://ehtg.org/

Results

Incidence of cancer by age, genetic variant and gender. Survival after cancer. Results of intervention (international guidelines).

Conclusion

The results migrate knowledge on Lynch syndrome from expert opinions based mainly on retrospective studies to assumption-free empirical observations in carriers subjected to follow-up according to accepted clinical guidelines. The interactive website www.PLSDE.eu returning risk for any single case when indicating age, gender and gene is referred to for clinical use by InSiGHT and others.

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N41

Correspondence: R. A. Zupparo
Aim
Screening for small-bowel cancer (SBC) is not yet included in surveillance guidelines for LS. In 2016 Mallorca group advised may be appropriate in MSH2 and MLH1 mutation carriers, after 40 years. Aim of the study was to determine SBC incidence in asymptomatic LS patients by means of video capsule endoscopy (VCE).

Method
Two prospective VCE databases were retrospectively reviewed to identify consecutive asymptomatic LS patients, compared with a group of patients who underwent VCE for obscure gastrointestinal bleeding (OBS).

Results
25 LS patients and 280 OBS patients were enrolled by two Italian centers. In 91.5%, caecal visualization was achieved. SBC was detected in two LS patients and three OBS patients (p=0.06). The two groups have a significant statistically different mean age (SD): 41.3 y±14.0 y in LS group and 62.9 y±17.2 y in OBS group. Besides SBC, LS patients and OBS patients have statistically significant difference in incidence of vascular lesion, angiectasia and minute polyps.

Conclusion
The prevalence of SBC in asymptomatic patients with LS was 8% vs. 1.1%. Although the incidence of SMC did not reach statistical significance, a trend through statistically significant difference was observed and this suggests further multicentric studies are needed.

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N43

Correspondence: N. Taylor

Aim
Evidence indicates that hospitals face infrastructural, psychosocial and environmental barriers to detecting Lynch Syndrome (LS) patients. In Australia, less than half of all high-risk colorectal cancer (CRC) patients are being referred for LS genetic testing. This study aims to compare the effectiveness and cost-effectiveness of two implementation approaches for increasing the proportion of CRC patients with risk-appropriate completion of the LS testing and referral pathway.

Method
This randomised controlled trial will test the Theoretical Domains Framework Implementation approach against a non-theory-based implementation approach in eight large Australian hospitals. Site based healthcare professionals will be trained to lead the following process: 1) Baseline audits, 2) Form Implementation Teams, 3) Identify practice change behaviours, 4) Identify/confirm barriers to change, 5) Generate intervention strategies, 6) Support intervention implementation, 7) Evaluate practice/culture change. Theoretical and non-theoretical components are distinguished in 4-5.

Results
Progress to date of baseline data analysis will be presented. Plans for the analysis of health and economic outcomes of each implementation approach to be estimated using “POLICY1-Lynch” will be provided.

Conclusion
This will be a world first study to compare theory-based and non-theory based approaches to evidence translation in healthcare, and to incorporate these findings into existing microsimulation models to accurately assess implementation cost-effectiveness.
Aim
The use of pan-chromoendoscopy (CE) for surveillance in Lynch syndrome is currently recommended despite low evidence. We aimed to demonstrate that high-definition white-light endoscopy (WLE) is not inferior to CE for detection of adenomas.

Method
Patients with confirmed germline mismatch repair mutation were prospectively randomized 1:1 to WLE or CE performed by endoscopists devoted to high-risk conditions of colorectal cancer. The main outcome was the adenoma detection rate.

Results
256 patients (60% women; age 47±14y) were included in 14 centers. The detection rate of lesions in WLE versus CE group were: adenomas 28.1% versus 34.4% respectively (p=0.281), total polyps 50.0% versus 57.7% (p=0.004), proximal serrated lesions (SL) 10.2% versus 11.7% (p=0.689), sessile SL 5.5% versus 3.9% (p=0.554) and advanced adenomas 7.8% (4.3%-13.7%) versus 3.9% (1.6%-3.9%) (p=0.183) respectively. The mean (standard deviation) of lesions per patient for WLE versus CE were: adenomas 1.04 (1.37) versus 0.86 (1.04) (p=0.670), proximal SL 0.25 (0.56) versus 0.25 (0.61) (p=0.426), sessile SL 0.10 (0.31) versus 0.11 (0.67) (p=0.660), left-sided SL 0.21 (0.55) versus 0.53 (1.04) (p=0.002) respectively. The withdrawal time (minutes) for WLE and CE were 13.5 (5.63) versus 18.37 (7.57) (p<0.001) respectively.

Conclusion
In a scenario with expert endoscopists, WLE is an optimal and efficient endoscopic technique for surveillance of Lynch syndrome patients.

Correspondence: M. Marabelli

Aim
To validate the performance of IHC testing ofMismatch Repair (MMR) proteins in patients with LS spectrum cancers.

Method
We analyzed MicroSatellite Instability (MSI) on 461 cancers (378 colorectal, 64 gynecological, 19 other sites). IHC analysis of MMR proteins in patients with LS spectrum cancers.

Results
Eight patients had double somatic hits in their tumors. Two patients had a germline de novo mosaic variant of MSH2 with low variant allele frequency (9% and less than 2%). Those variants were missed by NGS analysis in lymphocytes DNA. Their identification in tumors allowed a targeted NGS reanalysis. In both cases, these variants were found to be heterozygous in one of the offspring.

Conclusion
These mosaic cases confirm that identification of the mechanism that causes tumors in LLS is crucial for genetic counselling and guiding screening of patients and their relatives.

Correspondence: C. Colas

Aim
Lynch-like syndrome (LLS) patients have tumors with Microsatellite Instability but no germline variant in Mismatch Repair genes (MMR) or somatic methylation of the MLH1 promoter. Double somatic hits are the usual explanation for these cases. Our purpose was to find other explanations, such as mosaicism, that could explain LLS and have an impact on genetic counselling.

Method
We analysed the MMR genes in frozen tumor tissue samples by NGS for 28 LLS patients. When a tumoral variant was found, we performed a targeted re-examination of the germline NGS results with lower detection rates and targeted Sanger analysis in normal adjacent tissue DNA and lymphocytes DNA from offspring when available.

Results
Eight patients had double somatic hits in their tumors. Two patients had a germline de novo mosaic variant of MSH2 with low variant allele frequency (9% and less than 2%). Those variants were missed by NGS analysis in lymphocytes DNA. Their identification in tumors allowed a targeted NGS reanalysis. In both cases, those variants were found to be heterozygous in one of the offspring.

Conclusion
These mosaic cases confirm that identification of the mechanism that causes tumors in LLS is crucial for genetic counselling and guiding screening of patients and their relatives.
Results
Four FSP neoantigens derived from common cMS mutations in the genes Nacad, Max, Xirp1, and Senp6 elicited strong antigen-specific cellular and humoral immune responses. Based on the cMS mutation data, a vaccine with these four FSP neoantigens is predicted to cover about 75% of cancers in Lynch mice.

Conclusion
We have identified four immunogenic FSP neoantigens derived from commonly mutated cMS in murine Lynch syndrome colorectal cancers. This allows evaluating the concept of cancer-preventive neoantigen vaccines in mouse models of Lynch syndrome, including longitudinal monitoring of immune responses and combination with different adjuvants and chemoprevention approaches.

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N50

Correspondence: A. Ahadova

Aim
For distinguishing Lynch syndrome patients from sporadic microsatellite unstable (MSI) patients, BRAF V600E testing has become one of the most important tools. In order to analyze the discriminatory power of BRAF mutations in different age groups, we looked at the age distribution of BRAF mutations in MSI colorectal cancers.

Method
Age at diagnosis and BRAF mutation status were retrieved for unselected series of MSI colorectal cancers (n=151) from publicly available databases (DFCI) and the DACHS cohort.

Results
The prevalence of BRAF V600E mutations in MSI cancers strongly increased with age at diagnosis, with 87% of BRAF mutations occurring after the age of 65. There was no patient with a BRAF mutation under the age of 50, and the youngest patient with a BRAF mutation was 52 year old.

Conclusion
Our data demonstrate that BRAF mutation testing to exclude Lynch syndrome has very limited value in patients younger than 50, as the likelihood of detecting BRAF mutation in a patient under 50 is close to 0%. Reports of BRAF mutations in 1-2% of cancers from proven Lynch syndrome mutation carriers call into question the role of BRAF mutations as a bona-fide exclusion marker for Lynch syndrome.

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N52

Correspondence: A. Ahadova

Aim
The onset of mismatch repair (MMR) deficiency in Lynch syndrome-associated tumors has been discussed to be a late event of pathogenesis. Since the time point of MMR deficiency onset and its consequences have a direct impact on the selection of suitable therapeutic and preventive measures, we aimed to reconstruct the sequence of mutational events in Lynch syndrome cancers.

Method
MMR protein expression and mutational signatures were analyzed to address the time point of MMR deficiency in Lynch syndrome adenomas and carcinomas from public databases and our own cohort.

Results
Using qMSI for 40 target genes in MSI colorectal cancers (n=139) we demonstrate that most indels in MSI cancer are single-nucleotide deletions (77%) followed by two-nucleotide deletions and single-nucleotide insertions (21%). Neoantigen-inducing mutations were surprisingly similar across different MSI cancers.

Conclusion
The qMSI algorithm is a powerful tool to identify driver genes and mutational neoantigens in MSI cancer. The identification of shared, recurrent neoantigen-inducing mutations indicates that a vaccine for tumor prevention in Lynch syndrome is highly promising.

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):NS3
Correspondence: M. Suerink

Aim
Diagnosing Lynch Syndrome caused by a MSH6 mutation can be challenging due to the relatively frequent occurrence of discordant immunohistochemistry staining (i.e. MSH6 positive staining) and microsatellite stable phenotype. The aim of this study is to describe to what extent discordant phenotypes occur in colorectal and endometrial carcinomas (CRC/EC) in MSH6 families.

Method
Data were collected from 192 MSH6 families with a confirmed segregating pathogenic germline variant ascertained from Dutch family cancer clinics.

Results
The data consists of 9719 family members and 838 proven mutation carriers. MSH6-mutation carriers with CRC or EC (n=306) were included in the study, accounting for 219 CRCs and 122 ECs. Of the 219 CRCs, 15 were excluded in the study, fulfilling the Bethesda criteria. The IMRC has the potential to increase our understanding of the geographic distribution of Lynch syndrome.

Conclusion
MSH6 germline or tumor DNA analysis - preferably as part of a larger MMR testing as is currently standard in most western countries. In most cases the diagnosis of LS can be excluded by somatic sequencing through the demonstration of double somatic mismatch repair (MMR) mutations.

Correspondence: J. Reece

Aim
The IMRC contains data from 4624 Lynch families from 22 countries. We examined the geographical distribution of MMR mutations.

Method
Pedigree data includes: country, MMR mutation and cancer history. Frequency of each variant was calculated by geographical region.

Results
Of the 1578 unique MMR variants (MLH1=568, MSH2=582, MSH6=293, PMS2=135), the two most commonly reported variants were: Gene: Variant (number of families with variant):
MLH1: North America: c.350C>T (26), c.1852_1854del (22); Europe: c.1489dup (48), c.676C>T (28); South America: c.350C>T (6), c.1276C>T (6); Asia: c.381_453del (11), c.1852_1854del (4); Australasia: c.1852_1854del (12), c.350C>T (10)
MSH2: North America: c.942+3A>T (88), c.2176_2186del (76); Europe: c.942+3A>T (130), c.1165C>T (25), c.1786_1788del (25); South America: c.942+3A>T (2), c.1077_1176+1del (2); Asia: c.1457_1460del (19), c.942+3A>T (5); Australasia: c.942+3A>T (16), c.2502_2508del (8)
MSH6: North America: c.3261dup (18), c.2731C>T (12); Europe: c.3261dup (29), c.2731C>T (16), c.3261dup (2) ; South America: c.1519dup (2) ; Asia: c.3261dup (2); Australasia: c.3261dup (7), c.1571dup (5)
PM2: North America: c.137G>T (28), c.736_741delins (19); Europe: c.736_741delins (14), c.1882C>T (6)
South America: c.2186_2187del (2), c.2192_2196del (2); Asia: c.1572del (2), c.861_864del (2)
Australasia: c.736_741delins (11), c.989_996_1144+706del (4)

Conclusion
Some variants are frequently identified across geographical regions but heterogeneous distribution was found for other common variants. The IMRC has the potential to increase our understanding of the geographic distribution of Lynch syndrome.

Guy’s Regional Genetics Service
Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N56
Correspondence: B. Desouza

Aim
UK guidelines recommend that all newly diagnosed colorectal cancers (CRCs) be screened for mismatch repair deficiency (MMR-D) that may be indicative of Lynch syndrome (LS). Current diagnostic approaches, will fail to detect MLH1 promoter hypermethylation or a germline mutation in approximately 60% of suspected LS cases. For Amsterdam families, however, performing sequential testing would be more cost-effective than concurrent testing (£67 vs. £1256 per proband).

Method
We have used our clinical data from over 1100 families to model costs for different diagnostic strategies for LS that integrate germline and somatic testing. Outcomes were correlated to family history category of either revised Bethesda guidelines or modified Amsterdam criteria.

Results
Modelling shows that for Bethesda families, performing concurrent germline and somatic testing would be more cost-effective than sequential germline and somatic testing (£523 vs. £940 per proband). For Amsterdam families, however, performing sequential testing would be more cost-effective than concurrent testing (£67 vs. £1256 per proband).

Conclusion
LS diagnostic strategies for CRC cases could be accelerated and simplified by concurrent germline and somatic testing. Moreover, our data suggests that this approach is more cost-effective than sequential testing in Bethesda families.
The cost of identifying Lynch syndrome carriers in Australia

M. Dillon1, 2, M. A. Jenkins2, D. D. Buchanan2, D. A. Ouakrim2, L. Flander2
1Aalto University, Finland; 2The University of Melbourne, Australia

Correspondence: M. Dillon

Aim
We estimated the cost of different screening strategies to identify Lynch syndrome (LS) mutation carriers in Australia.

Method
We used a microsimulation to model costs of DNA mismatch repair gene mutation testing for five target population subgroups: i) incident colorectal cancers (CRCs) diagnosed under age 50; ii) under age 70; iii) at any age; iv) unaffected people aged 20-50 years; and v) unaffected people aged 20-80 years. For the incident CRC subgroups, three strategies were considered: multi-gene panel testing; immunohistochemistry (IHC) followed by a multi-gene panel test; and IHC followed by MLH1 methylation testing and a multi-gene panel test. For the strategies targeting the general population (no CRC), only multi-gene panel testing was considered.

Results
IHC followed by panel testing yielded the lowest cost per mutation carrier identified at AUS$2,292, AUS$6,331, and AUS$11,182 for the approaches targeting incident CRCs under age 50, 70, and any age respectively. For the general population approaches, testing unaffected people aged 20-50 years was the cheapest option (AUS$112,282 per carrier identified). Testing incident CRCs under age 50 identified the highest number of carriers (11,774 per 100,000 probands).

Conclusion
Testing incident CRC cases under age 50 years appears as the most effective and cheapest strategy to identify LS mutation carriers.

Lynch syndrome registries in Latin America

Correspondence: M. Domínguez-Valentín

Aim
Despite significant advances in cancer genetics research in Latin America, the access to routine medical care for hereditary cancer patients is still limited.

Method
International survey including selection criteria, clinical and genetic information was sent out to the 26 recently described LS programs from 10/33 countries of Latin America (Vaccaro et al. submitted).

Results
Amsterdam or Bethesda guidelines were mostly used to select patients for a tumor screening test and/or genetic MMR sequencing in 15/26 LS programs from public (n=7) or private (n=8) hospitals located in large urban areas from Argentina, Brazil, Chile, Colombia, Mexico, Peru and Uruguay. 717 LS carriers have been identified with a mean age of 42.5 years (range 32-50.9) and a mean of 3.7 follow-up years (range 1-9.6).

Conclusion
Several research projects and publications have been implemented, generating knowledge of MMR variants in these populations to bring additional awareness to medical professionals and public health leaders. Participation in PLSD and international collaborations have been initiated to support the implementation of genetic testing and research in most of the countries of Latin America.

Genetic and clinical features in Russian patients with Lynch syndrome

D. Y. Pikunov, A. S. Tsukanov, S. I. Achkasov, V. P. Shubin, D. A. Semenov
State Scientific Centre of Coloproctology

Correspondence: D. Y. Pikunov

Aim
Up to 3% of all colorectal cancers are connected with Lynch syndrome (LS), which is caused by mutations in mismatch repair (MMR) genes. According to the literature the main manifestations of LS are tumors of right colon, endometrium, ovary, kidney and ureter, stomach etc. at the age of <45.

Method
Between 2012 and 2017 ninety seven patients with primary tumors at the age of <45y.o. and/or with familial history were included in the study. All the tumors were analyzed for microsatellite instability (MSI). In patients with MSI the genes of MMR were examined.

Results
LS was diagnosed in thirty three (34%) out of 97 patients. Twenty of them (60%) had MLH1-gene mutation, 11 (34%) had MSH2-gene mutation, 2 (6%) – MSH6-gene mutation. The median age of primary tumor appearance in patients with LS was 38±7y.o. The primary tumor site was colorectum in 24 (73%) patients, uterus – in 8 (24%) patients, pyometrium – in 1 (3%). Among the patients with colorectal cancer right colon lesions were registered in 5 (24%) cases and left colon lesions – in 19 (76%).

Conclusion
In contrast to European patients, Russian patients with LS have MLH1-gene mutation in 60% cases, early-age appearance of colorectal cancer and preferable left-side lesions.

**Clinical and molecular characterization of Lynch-like syndrome**

M. D. Picó, R. Jover, M. Giner-Calabuig, M. Juarez, M. Alustiza-Fernández, O. Murcia, R. Jover, X. Lloró, R. M. Nicola

**Aim**

Hereditary non-polyposis colorectal cancer defines the development of colorectal cancer within the spectrum of presentation of Lynch syndrome. A major characteristic of CRC in Lynch individuals is the failure to metastasize despite the large tumor size. Herein we present a case of metastatic CRC in a patient with a pathogenic MSH2 / MSH6 mutation.

**Method**

A 68 year old Caucasian male patient with a history of right nephrectomy 25 years after a ureteral cancer. Mismatch repair analysis confirmed MSH-H for MSH2 / MSH6. The patient now presented with a rectal cancer and to date he had not been recommended genetic testing. He underwent an anterior rectal resection with a protective loop ileostomy in December 2017 for colorectal cancer of the recto-sigmoidal junction (pT3N0pV0pL0G2R0). An abdominal wall mass was found 10 months after surgery at the former ileostomy site during follow-up, which was completely excised with negative margins. Five months later, computed tomographic scans of the abdomen suspected recurrent metastasis including a peritoneal mass. Surgical exploration was performed.

**Results**

The abdominal wall mass was completely removed with negative margins. Equally, limited peritoneectomy was performed during the second exploratory laparotomy. Histopathology confirmed the presence of metastasis from a colorectal cancer with loss of MSH2 / MSH6 6 proteins on immunohistochemistry. The patient was discussed at the interdisciplinary oncologic board after which adjuvant checkpoint inhibitor therapy was recommended. However, the insurance was not willing to pay for this treatment.

**Conclusion**

Histopathologic features including loss of MSH2 / MSH6 protein expression on immunohistochemistry in both the primary tumor as well as the metastatic lesions confirms the presence of metastatic seeding. This provides evidence for a metastasis of CRC in a patient with Lynch syndrome and disapproves the currently accepted non-metastatic theory. We conclude that, we cannot rely on the theory and are mandated to adhere to all principles of oncological surgery and also of stringent follow-up.

**Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N65**

**N64**

**Peritoneal and abdominal wall metastasis following colectomy in a patient with Lynch syndrome. Is it time to rethink the non-metastatic theory?**

P. C. Ambe, D. Goedde, G. Möslin

**Aim**

Hereditary non-polyposis colorectal cancer defines the development of colorectal cancer within the spectrum of presentation of Lynch syndrome. A major characteristic of CRC in Lynch individuals is the failure to metastasize despite the large tumor size. Herein we present a case of metastatic CRC in a patient with a pathogenic MSH2 / MSH6 mutation.

**Method**

We performed whole exome sequencing in a cohort of 27 LLS patients. We performed an analysis to identify rare likely pathogenic variants that could be predisposing to cancer. Only high-quality called variants, present with a population frequency <2.10-5 were included.

Based on the fact that the mutations in the MMR genes could be passenger mutations that drive further instability, a targeted analysis including a comprehensive list of DNA repair genes was also included.

We also performed tumor exome analysis from the matching samples to search for somatic hits.

**Results**

We identified 4 LLS patients with rare germlinal variants in the following genes: AXIN1, PIWIL3, CD109, RECOL5 and GEN1. No somatic second hit was found in any of these genes. 2/8 cases where we could evaluate somatic events had a somatic mutation in one MMR gene
and I showed LOH of the other copy. One tumor had a single mutation in a MMR gene and in one case I did not identify any somatic alterations.

**Conclusion**

Based on these results we hypothesize that there is a group of patients with predisposition to CRC due to a germinal variant in one allele that triggers genomic instability. But there is also another group of patients where it could be due to a biallelic somatic mutation in MMR genes.

**The ICCon Australian database of mismatch repair variants**

F. Macrae1, J. P. Plazzer2, B. Thompson2, A. B. Spurdle3, G. Mitchell4, P. James5

1Dept of Colorectal Medicine and Genetics, The Royal Melbourne Hospital, Australia; 2School of Population Health, University of Melbourne, Australia; 3QIMR Berghofer Medical Research Institute, Queensland, Australia; 4Chair ICCon Investigators; 5Head, Parkville Precinct Familial Cancer Clinics

**Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N66**

**Correspondence:** F. Macrae

**Aim**

To systematically collect DNA mismatch repair variants identified by clinical testing in Australian families.

**Method**

Initial attempts through the HVP sourced variants from laboratories by streamlining with Laboratory Information Management Systems. Subsequently, a grant was awarded from the New South Wales Cancer Council to build a database of pathogenic (Class 4 and 5) variants identified in the cancer genes through the familial cancer clinics (FCCs); a collaboration across the clinics (ICCon) was formed to facilitate this.

**Results**

The ICCon database holds information about MMR gene pathogenic variants in adult carriers as follows: MLH1 124 (90 unique), MSH2 121 (94), MSH6 68 (50), PM2S 36 (25); totalling 349 (259). Ten discordant interpretations between clinics and/or InSIGHT’s classifications were resolved as part of the ICCon process. Importantly, clinical and other data to assist VUSs was accessible from the FCCs.

**Conclusion**

Sourcing variants via the FCCs has proved feasible. The ICCon database has contributed to variant interpretation internationally, including InSIGHT’s Variant Interpretation Committee and, in part, the PLSD. ICCon is working to achieve governance around transforming the variant database to a national registry, to permit changes in governance around transforming the variant database to a national registry, to permit changes in management, such as when new information emerges through contemporary experience or research.

**Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N67**

**Correspondence:** A. K. Win

**Aim**

Previous estimates of colorectal cancer risk for Lynch syndrome are averages over hundreds of different mutations in these genes.

Reason for heterogeneity of cancer risk within specific variants in each gene is unknown.

**Method**

We estimated colorectal cancer risk for MSH2 c.942+3A>T variant using 234 families from the International Mismatch Repair Consortium. Age-specific cumulative risks (penetrance) and 95% confidence intervals were estimated using a modified segregation analysis with appropriate ascertainment conditioning and allowing for risk to vary between families by fitting a polygenic effect.

**Results**

The estimated average cumulative risks to age 70 years (95% confidence intervals), were 56% (38%-78%) for males carriers and 45% (28%-67%) for female carriers. However, the lifetime risks for different people were estimated to vary widely about these average risks (p=0.001). For carriers of this specific variant, 26% of males and 16% of females had colorectal cancer risk less than 20%; and 24% of males and 37% of females had risk greater than 70%.

**Conclusion**

Even for a specific variant in a DNA mismatch repair gene, there is a wide range of colorectal cancer risks. This is consistent with the existence of strong modifiers of risk, that if known, could be used to provide personalized risk of colorectal cancer for Lynch syndrome.

**Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N68**

**Correspondence:** G. M. Cavestro

**Aim**

Life-time risk of pancreatic cancer (PC) is 1.3%. Familial PC (FPC) have over 5% risk, due to family history and/or germline mutations. FPC accounts for 4-10% of all PCs, and germline mutations are detected in 5-10% of FPCs.

**Method**

Clinical and pathological data were retrieved during a single-session visit in gastroenterology and genetics from 2016 to 2017. FPC underwent either pancreatic endoscopic ultrasound (eUS) or magnetic resonance (MR) and Next Generation Sequencing analysis.

**Results**

57FPC were evaluated; 17 had a personal diagnosis of PC. 29(50,9%) had ≥2 relatives affected, of whom ≥1 was a first-degree relative (FDR); 11(37,9%) had PC. 11(19,3%) had ≥3 relatives affected (1 had PC). 6(10,5%) had Lynch Syndrome with ≥1 FDR (1 had PC), 2(3,5%) had hereditary pancreatitis and 9(15,8%) BRCA1/2 mutation with 1 FDR affected (5 had PC). 17(29,8%) were genetically confirmed: 6 LS (35,3%), 2 PRSS1 (11,8%), 6 BRCA2 (35,3%), 1 BRCA1 (5,9%), 2 PALB2 (11,8%). 8 showed a Variant of Unknown Significance (VUS). 21(36,8%) underwent eUS, revealing 8 PC, 1 intraductal mucinous neoplasia, 1 pseudopapillary lesion. 16(28,1%) underwent MR, revealing 7 CP, 1 IPMNs, and 3 cystadenoma.

**Conclusion**

A multidisciplinary approach enriches the proportion of patients with genetically confirmed FPC from 5-10% to about 30% of all FPC.
N69 Interpretation of inheritable DNA variation: room for error across genetic services?  
M. Daly1, J. P. Plazer2,3, F. Macrae2 3

Correspondence: F. Macrae  
Aim  
We aimed to evaluate the frequency of conflicts in interpretation of pathogenicity for gene variants in the mismatch repair genes MLH1, MSH2, MSH6 and PMS2 between InSiGHT’s Variant Interpretation Committee (VIC) and those provided by submissions from primary sources to ClinVar.  
Method  
Variant interpretation submissions for the four genes within ClinVar were compared and with those of the InSiGHT VIC. Factors that could account for the discordance were assessed including classification guidelines, evidence sources, research only interpretations.  
Results  
A total of 9,921 unique variant submissions were assessed. 584 interpretation conflicts were identified when compared to the VIC’s classifications. 98 of the conflicts were considered clinically significant. 5,862 variant interpretations have only one submitter. Methods of interpretation by submitters were heterogeneous and included clinical testing, research, and literature searching, accounting for much of the discordance.  
Conclusion  
Discordant interpretations between submitters represent opportunity for inconsistent counselling for families with the same variant, with potentially serious clinical consequences. Improvements in data sharing, increased support, coupled with increased awareness of the limitations of current generic methods for variant interpretation, and greater utilisation of expert panels who have access to comprehensive information and use clear gene specific criteria, are essential for optimal interpretation and safe clinical counselling.

Aim  
Presenting the story of The Danish HNPPC-register and methods used for datacollection  
Method  
The Danish HNPPC register was established in 1991 as a private research register, later developing into a national database financed within the National Public Health care System. Epidemiological, clinical, and genomic data generated all over the country on 6.297 CRC families hereof 443 Lynch families are registered. Initially paper-based reports were sent to and typed into the database. Later a model for electronic exchange of data between laboratories, departments and the register in an EC funded project to prevent cancer by optimizing screening, digitization of data transport and combining genotype-phenotype information, sufficiently usable and generic to be implemented in other countries were developed. As medical data are heterogeneous, focuses were on integration, development of classification systems and communication standards. Identified gaps and status of usability will be presented.  
Results  
Data in the HNPPC register belongs to the financing Capital Region and the multidisciplinary scientific societies providing data. To achieve commitment and ownership representatives off all parties are invited into the Scientific Board and Steering Comity of the register, where rules for ownership and data delivery are decided.  
Conclusion  
The Danish HNPPC-register is national and comprehensive, and researchers can request data via the Scientific Board.

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N75

Correspondence: L. Moreno

Aim
Assess the psychological impact of genetic testing, evaluate changes in social life and behaviour, and estimate if personality influences the use of medical resources.

Method
Ten adults undergoing predictive genetic testing for cancer predisposition syndromes were included between January and March 2017. Demographic information, personality traits, psychological distress, behaviour in some daily activities and medical resources use were collected before testing and two months after results disclosure.

Results
High pre- and post-test psychological distress was associated to low education levels, having psychopathological history, pursuing testing for offspring, and being recruited at IEO (p<0.05). It was also associated with high negative affect, detachment, psychoticism and novelty seeking, and low reward dependence, self-directiveness, cooperativeness, and persistence (p<0.05). High post-test distress was also associated with having pre-test psychological distress (p<0.05). It would be important to know our counselees’ personality because it gives us the opportunity to know who to offer more support and how to personalize genetic counselling.

Conclusion
Our results suggest that there are some personality traits which can influence psychological distress in individuals undergoing predictive genetic testing. Further studies need to be performed in order to extrapolate these results to this particular population.

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N77

Correspondence: E. Ryan

Aim
Microsatellite instability (MSI) is reflective of a deficient mismatch repair system (dMMR) and occurs in 15% of all colorectal carcinomas (CRC). This most frequently occurs due to sporadic or constitutional mutations in mismatch repair genes. Mismatch repair (MMR) status is often identified by immunohistochemistry (IHC) for mismatch repair proteins (MMRPs) on CRC resection specimens. IHC testing performed on endoscopic biopsy material may be as reliable as that performed on resected specimens. We aimed to evaluate the reliability of MMR IHC staining on preoperative CRC endoscopic biopsies.

Method
A retrospective search of our institution’s histopathology database was performed. Patients with CRC who had MMR IHC performed on both their preoperative endoscopic biopsy and surgical resection from 2010 - 2016 were included. Concordance of MMR staining between these specimens was assessed.

Results
53 patients had MMR IHC performed on both their preoperative endoscopic biopsy and resection specimens; 10 patients (18.87%) demonstrated loss of 1 or more MMRPs on their endoscopic tumour biopsy. The remainder (81.13%) demonstrated preservation of staining for all MMRPs. There was 100% agreement in MMR IHC status between specimens in all cases (κ = 1.000, p < 0.000), with a sensitivity of 100% (95% confidence interval [CI]: 69.15-100) and specificity 100% (95% CI: 91.78-100) for detection of dMMR.

Conclusion
Endoscopic biopsies may provide a suitable source of tissue for MMR IHC analysis. This could allow a number of advantages to both clinicians and patients in the management of CRC.

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N79

Correspondence: P. Janega

Aim
The immune system plays crucial role in the development of the neoplastic diseases. Colorectal carcinoma is one of the most frequent oncological diseases with high mortality rate also in Slovak republic. Its development is the result of environmental, genetic and epigenetic changes accumulation leading to neoplastic transformation. Tumor-specific mutations manifest by neoantigens activating the immune system. The aim of the work was to evaluate the antitumor immune microenvironment in association of tumor grading.

Method
Archival surgical specimens of CRC were evaluated and graded according to the WHO criteria. Immunohistochemically detected CD4, CD8 and CD68 positive cells were evaluated morphometrically and expressed as % of the evaluated area.

Results
Neoplastic as well as the surrounding tissues were infiltrated by the three cell types in unchanged ratios, with predomination of CD68+ histiocytes. With the increasing grade there was significant decrease of CD4+ and CD68+ cells and a clear decrease of CD8+ cells at the edge of significance, of infiltration of the tumor tissue. Changes in the peritumoral tissue infiltration were not significant.

Conclusion
Our findings support the idea of tumor suppressing activity of the anti tumor immunological response and that it plays an important role in progression of the neoplasm. Supported by the APVV-14-0318 grant.

Aim
Duodenal polyposis and cancer represent significant disease manifestations in patients with FAP and MAP. This study aims to determine the extent and incidence of duodenal disease in patients with MAP to establish whether upper GI surveillance recommendations developed for patients with FAP are also appropriate for MAP.

Method
A long-term prospective collaboration has been established. Demographic and genotype information and details of endoscopic surveillance and therapy has been collected on 394 MAP patients to date.

Results
63/394 had duodenal disease at index endoscopy (16%) at a median age of 54 years (range; 33-81): this was Spigelman stage I in 37 patients (58.7%), stage II in 12 (19%), stage III in 10 (15.9%), stage IV in 1 patient and three patients had cancer (4.8%). During 1417 follow up years, five further patients progressed to stage IV disease at a median age of 63 (range; 51-67) and one patient developed cancer.

Conclusion
Perhaps MAP will appear to develop fewer duodenal polyps at a more advanced age than is reported in FAP. Nonetheless, progression to advanced disease and cancer may occur despite surveillance. We are collecting prospective data that may inform development of a more appropriate surveillance strategy for upper GI disease in MAP.

Aim
Duodenal polyposis and cancer are important yet poorly understood causes of morbidity and mortality in FAP and MAP patients. We aimed to characterise the genomic and transcriptomic signatures associated with duodenal adenomas from patients with FAP and MAP, to better understand duodenal tumorigenesis in these hereditary disorders.

Method
A series of 67 samples from patients with a genetically confirmed diagnosis of FAP or MAP were subjected to whole transcriptome sequencing, consisting of 44 duodenal adenomas (FAP n=29, MAP n=15) and 23 duodenal normal mucosa (FAP n=15, MAP n=8). Outcomes were compared to exome sequencing data from 50 duodenal adenomas (FAP n=25, MAP n=25).

Results
We found distinct gene expression profiles in FAP and MAP duodenal adenomas which were absent from the respective normal mucosa. MAP adenomas harboured aberrations in RAS signalling and immune system stimulation, whilst evidence for dysregulation of prostanoid synthesis and NOTCH signalling were found in FAP adenomas. Whole exome analysis revealed that MAP duodenal adenomas carried more somatic mutations than FAP (p=0.0226). Recurrently mutated genes...
in duodenal adenomas included known drivers (APC, KRAS) and additional potential duodenal-specific tumour initiators.

**Conclusion**
The identification of commonly deregulated pathways contributes to our understanding of duodenal tumorigenesis in the context of FAP and MAP.

Survival recommendations for first-degree relatives of patients with unexplained multiple colorectal adenomas: a nationwide survey of UK regional genetic services

B. Desouza, A. Elinel, N. Jakharia-Shah, G. Norbury, A. Kulikarni, D. Ruddy, V. Tripathi, A. Shaw, L. Izatt
Guy’s Regional Genetics Service
Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N83

**Correspondence:** B. Desouza

**Background**
Patients with multiple colorectal adenomas (MCRA; 10-100 adenomas cumulatively) without a known genetic cause are increasingly being diagnosed in the UK. Germline monoallelic APC or biallelic MUTYH mutations are not identified in the majority of patients. Possible explanations include: APC mosaicism, cryptic mutations, mutations in other polyposis genes, and polygenic inheritance. Some guidelines have recommended regular colorectal surveillance for first-degree relatives of this patient group, but currently there is no national UK guideline.

**Method**
We conducted a national survey of UK regional genetic services to explore management practices for first-degree relatives of patients with MCRA without a known genetic cause. A web-based survey was sent by email to the cancer genetic lead clinicians at the 24 regional genetics services. The survey was primarily designed to assess survival recommendations for first-degree relatives of MRCA patients, and to determine whether recommendations varied according to the total number of adenomas and age of onset. Testing criteria and genetic investigations were also assessed for patients with MCRA.

**Results**
National survey results are presented.

**Conclusion**
The survey aims to highlight variation in the management of this patient group and their first-degree relatives in the UK.

**N84**
Mutations in MutYH gene among Russian patients with colorectal polyps

Y. A. Shelygin, V. N. Kashnikov, A. M. Kuzminov, M. K. Toboeva, D. Y. Pukunov, V. P. Shubin
State Scientific Center of Coloproctology
Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N84

**Aim**
MutYH-associated polyposis is one of the important inherited colorectal cancer syndromes. It is caused by germline mutations in the MutYH gene. Biallelic MutYH mutations are the genetic reason of an autosomal recessive mode of inheritance but we also observed risk of developing polyposis in monoallelic MutYH gene mutation carriers of some populations. The aim of this investigation was to study frequency of germline mutations in MutYH gene among Russian patients with different number of colorectal polyps

**Method**
Germline mutations in MutYH gene were detected by PCR, SSCP, Sanger sequencing and NGS among 19 patients with 100 and more colorectal polyps; 93 patients with 4-99 polyps and 150 healthy controls.

**Results**
We found 11 germline mutations (8 biallelic and 3 monoallelic) in MutYH gene among 93 patients with 4-100 polyps and 2 mutations (1 biallelic and 1 heterozygous) in 19 patients with 100 and more colorectal polyps. We don’t found heterozygous mutations among 150 healthy controls

**Conclusion**
Frequency of germline mutations in MutYH gene among Russian patients with 4-99 and more than 100 colorectal polyps was 11.8% and 10.5% respectively.

**N87**
SELINA – clinical trial on lowering the risk of malignancies by optimizing selenium levels in females from families with hereditary breast cancer

J. Lubinski
Department of Genetics and Pathology, Pomeranian Medical University in Szczecin and Read-Gen Nut SA Poland
Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N87

**Aim**
Blood selenium (Se) levels associated with significantly lower risk of cancers has been identified in Polish females from families with hereditary breast cancers (HBC). For BRCA1 mutation carriers: 70-89 μg/l at age <50 yrs (OR~12) and 95-120 μg/l at age ≥50 yrs (OR~4); for females without detected BRCA1 mutation: 98-108 μg/l (OR~5).

The main goal of SELINA is validation of hypothesis that optimization of Se level can decrease the risk of malignancies.

**Method**
7000 females (including 1200 BRCA1 carriers) from families with HBC and deficiency or excess of Se are qualified to one of the arms: "placebo", observational, supplement (Sodium Selenite) or diet modification. Blood Se level will be measured and optimized during 5 yrs.

**Results**
Recruitment will be closed in 2018.

**Conclusion**
SELINA is the first trial aimed to decrease the risk of cancers by active control of blood selenium levels. Interested scientists are welcome for collaboration.

**N88**
The national Lynch Syndrome Registry of Finland (LSRFi)

T. Seppälä, K. Pylvänäinen, J. P. Mecklin
Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N88

The nationwide Lynch Syndrome Registry of Finland (LSRFi) was founded in 1982 to organize endoscopic surveillance for high-risk families with colorectal cancer (CRC). To date, there are 298 families with confirmed pathogenic variants of mismatch repair (MMR) genes. Currently, LSRFi organizes genetic counselling and predictive testing in research setting and co-ordinates endoscopic surveillance that takes place mostly in centralized public hospitals. Colonoscopy surveillance is offered from 25 years onwards, with 3-year interval for those with no prior cancer. LSRFi has access to national healthcare registries, such as registry for causes of death, parish registries and Finnish cancer registry.

About 3,000 individuals have undergone genetic testing, so far. In May 2018, there were total of 1,416 path_MMR carriers; 1,044 path_MLH1, 53 years for path_MSH2, 60 years for path_MSH6 and 48 years for path_PMS2. In 2015, about two thirds of eligible children (age >18 years) of verified path_MMR carriers had undergone predictive testing. Adherence to offered surveillance is high, well over 90%. CRC incidence, stage and survival do not differ from other countries compared to independent prospective datasets in Europe.

**Acknowledgements**
On behalf of the Lynch Syndrome Registry of Finland (LSRFi)

Argentinean Lynch syndrome registry: experience from Rosario
E. Spirandelli 1, A. Navés 1, S. Chialina 1, F. Spirandelli 1
1Servicio de Coloproctología y Asesoría Genética, Hospital Español Rosario, Rosario, Argentina; 2Instituto de Histopatología, Rosario, Argentina; 3Laboratorio Stem Rosario, Rosario, Argentina
Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N90

**Aim**
There is still no national hereditary or familial cancer registers in Argentina. With the mission of improving detection, prevention and management of high risk cancer population in Rosario, with a population of 1.198,528 inhabitants, the Asociación Civil de Estudio, Tratamiento, Investigación de Enfermedades Hereditarias de Rosario (ACETHIER) was established as a genetic reference center in 2005.

**Method**
Hospital Español is used to identify suspected Lynch syndrome (LS) families. The Amsterdam criteria (AMS) or Bethesda guidelines were mostly used to select cases for screening by immunohistochemistry (IHC) and/or microsatellite instability (MSI) analysis. Genetic testing was generally based on Sanger sequencing of MLH1, MSH2, MSH6, PMS2 and/or EPCAM. By the advent of next generation sequencing (NGS), we are recently using 17-multiplex gene panels including: APC, BMPR1A, CDH1, CHEK2, MLH1, MSH2, MSH6, PMS2, MUTYH, POLE, PTEN, SMAD4, STK11, PTEN, EPCAM and GBM1 (Ambry Genetics, USA). Patients are informed about their inclusion into the registry, which generally contained data on family history, clinical information, age at onset and results of DNA testing or tumour screening in the diagnosis of LS. Written informed consent was obtained from all patients during genetic counselling sessions.

**Results**
From our registry, 61 suspected families fulfilled AMS criteria or Bethesda guidelines. Seventeen families (28%) had MMR deficiency and underwent genetic MMR testing. Pathology MLH1 variants were identified in 3 (21%) families, path MLH2/EPCAM variants in 11 (72%) families and path PM2 variants in 1 family (7%). LS carriers have been identified with a mean age of 37.5 years (range 18-57) and a mean of 13 follow-up years.

**Conclusion**
The path MSH2 variants are the most frequently identified in our registry and we provides support to set or improve LS genetic testing in South America. In addition, despite the small number of our registry, we described patients with a young age of onset and/or a positive family history of LS-associated cancers without an identified pathogen variant, and may suggest the involvement of pathogenic variants in as yet undiscovered genes.

**Acknowledgements**
We would like to thanks Merv Dominguez-Valentin (Oslo University Hospital, Oslo, Norway), for her unconditional support and her effort, to be able to join all the research groups in Hereditary Colorectal Cancer from South America. She can lead this great Group, and we know that we will continue to grow.

**N91**

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N91

**Aim**
Registries in South America were initiated in the early 90’s with the help of Henry T. Lynch. The Programa de Cancer Hereditario (ProCanHe), is a multidisciplinary program established in 1996 at the Hospital Italiano, Argentina. The aim of the study is to update our 21-year experience to determine the applicability of genetic tests highlighting the most informative molecular findings in relation to Lynch syndrome mostly.

**Materials and methods**
Families undergoing genetic testing after genetic counselling between 1996-2018 were included. Data were obtained from a prospective IRB approved database. Clinical-epidemiological and molecular variables were analysed. Genetic tests were carried out after a genetic counselling session and obtaining the informed consent of the patient.

**Molecular testing**
Until 2015, the search for variants was carried out by PCR and Sanger sequencing of exons and adjacent intronic regions of MLH1 and MSH2. Then, sequencing of MLH1/MSH2/MSH6/PMS2/EPCAM genes was performed by NGS and large rearrangements were detected by MLPA. The variants were classified according to international databases. Variants with uncertain or unreported clinical significance were analysed In-silico using the PolyPhen, SIFT and/or Human Splicing finder 3.0 software.

**Results**
A total of 83 families (49 fulfilled Amsterdam Criteria [AC] and 34 Bethesda Criteria [BC]) were analysed. Pathogenic variants were found in 26 out of 83 (31.3%) families, been 23 pathogenic and 3 likely pathogenic. Splice site and large rearrangements represented 19.2% (5/26) and 11.5% (3/26) of the variants. 23% (6/26) of them were originally described in this series and 1 was a founding mutation from Piedmont, Italy. Affected genes include MSH2, MLH1, MSH6 and PMS2 (12, 11, 2 and 1 cases respectively). Mutation detection rates in AC and BT families were 48.9% (N=24) and 5.9% (N=2), p<0.01. Among AC families, those with identified mutation had a lower median age of cancer on set and higher incidence of extra-CCR cancer than those without identified mutations. Additionally, we have also studied other genes in patients with different clinical conditions included in the registry. We identified mutations in APC, MUTYH, BMPR1A, SMAD4, CDH1, BRCA1-2, CHEK2.

**Conclusion**
The multidisciplinary approach and the international collaborations allowed the correct implementation of the genetic tests. To our knowledge, this study is the first Characterization of AC families according to genetic tests in South America. This allowed the identification of AC families with different ages of onset and prevalence of extra-CCR cancers, as well as several significant variant not previously reported in international databases.

**N92**

Chilean hereditary colorectal cancer registry: experience from Clínica Las Condes
K. Alvarez, F. López-Köstner
Unidad de Coloproctología, Clínica Las Condes, Santiago, Chile
Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N92

**Aim**
Considering the lack of genetic studies in our country and the benefits resulting from being able to differentiate between carrier and non-carrier individuals, in 2003 we applied for grant funds offered by the Chilean government (FONDECYT). During 2004-2006, this support enabled us to implement the MSI and IHC analyses in tumors, as well as the detection of point mutations in APC, MLH1 and MSH2 genes. In 2009, with the aim of increasing the mutation detection rate, genetic studies were supplemented with deletion/duplication analysis by MLPA for APC, MLH1, MSH2 and EPCAM genes, and the identification of point mutations in MUTYH, MSH6, PMS2, STK11, PTEN, SMAD4 and BMPR1A genes. Today, we have broadened the genetic studies into gene panels (Invitae, USA), mainly in those patients whose tumor studies do not allow us to define a candidate gene or when the definition of the hereditary syndrome becomes quite difficult.

**Methods**
Patients are referred to the program of hereditary colorectal cancer for evaluation. Those that meet criteria are included into the registry,
which generally contained data on family history, clinical information, age at onset and results of DNA testing or tumor screening. Written informed consent was obtained from all patients during genetic counseling sessions.

Results
In our registry, we have an overall record of 221 suspected families (with 533 registered individuals), 107 are Lynch syndrome suspected families, 98 familial adenomatous polyposis, 11 Peutz-Jeghers syndrome, 2 juvenile polyposis, 1 Cowden syndrome and 2 hyperplastic polyposis. In total, 88 families present a mutation or variant of uncertain significant in APC (41), MUTYH (3), MLH1 (21), MSH2 (7), MSH6 (1), PMS2 (3), EPCAM (2), STK11 (8), PTEN (1) and SMAD4 (1) genes. In those families with pathogenic or likely pathogenic mutations, we have studied 386 relatives, of which, 223 are carriers and 163 are no carriers. All families have received clinical recommendations based on the National Comprehensive Cancer Network (NCCN) guidelines. Interestingly, 25 mutations have not yet been described in other studies, clearly demonstrating the relevance of evaluating different racial/ethnic populations like ours, which include an admixture of Amerindian and European –mainly Spanish – populations.

Conclusion
Our work shows the success to integrate multidisciplinary professionals as coloproctologists, PhD in biological sciences (genetic counselor), nurses, medical doctors from various disciplines, and the constant support of a psycho-oncologist. We would like to highlight our last challenge, a pioneering initiative in Latin America, which consisted in the creation of a Course of genetic counseling in hereditary cancer aimed for health care professionals belonging to oncology units.

Hereditary gastrointestinal cancer mutational registry In Uruguay
P. Esperon1,2*, F. Neffa1, N. Artagavyest1, M. Sapone1, C. Vergara1, F. Carusso1, A. Della Valle1
1Grupo Colaborativo Uruguayo; 2Facultad de Química, UDELAR
Montevideo, Uruguay
Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N93

Introduction
Since 1996, the Uruguayan Collaborative Group (UCG), a nonprofit organization is devoted to the registry, diagnosis, management and investigation of hereditary cancer. UGC is integrated by a multidisciplinary team of experts and represents in the country, a reference center for genetic counselling and risk assessment.

Objective: To present an updated Uruguayan mutation catalog for gastrointestinal (GI) hereditary cancer susceptibility

Methodology
The UCG registry is integrated by 1536 non-related families. 548 families (35%) are defined as GI-high risk population following the National Comprehensive Cancer Network 2018 guidelines. These families were classified as: Amsterdam I-II, Bethesda, Li Fraumeni, Peutz Jeghers, Familial Adenomatous Polyposis, MUTYH-Associated Polyposis, or Serrated polyposis syndrome. Selected probands for genetic testing signed informed consent prior to obtain saliva or blood samples.

Several DNA-analysis techniques were used over these 22 years, from Sanger sequencing alone (until 2010), Next Generation Sequencing of a group of genes and large rearrangements detection methods, to nowadays, panels of 30 genes.

Results
At present a total of 234 (43%) GI-high risk, non-related probands were tested and 63 families were diagnosed. We found 49 different mutations, classified according to ACMG as “Pathogenic” and distributed among the following genes: MLH1 (9), MSH2(11), PMS2(3), MSH6 (3), EPCAM(1), APC (11), STK11(2), NF1(1), FAN1(1), RAD51(1), SDHBI(1), BMPRIAI(1), MUTYH biallelic (3). A family carried a mutation class 4 (likely Pathogenic) in MLH1. In nine probands with a characteristic hereditary colon cancer phenotype, only MUTYH monoallelic mutations were found. An increasing number of variant of uncertain significance were found.

Conclusion
A research period of 22 years has unveiled the mutational spectrum of GI-high risk cancer of the Uruguayan population, allowing a broader vision regarding hereditary cancer profile in an understudied population. In spite of the large gene selection, only a few were involved in cancer predisposition, Lynch Syndrome, as expected, was the most frequent diagnosis, but with a relatively low pathogenic variant presentation.

Uruguayan hereditary breast and ovarian cancer syndrome registry: BRCA and non-BRCA pathogenic variants
P. Esperon1,2*, F. Neffa1, C. Acevedo1, G. Santander1, M. Sapone1, C. Vergara1, F. Carusso1, A. Della Valle1
1Grupo Colaborativo Uruguayo; 2Facultad de Química, UDELAR

Hereditary Cancer in Clinical Practice 2019, 17(Suppl 2):N94

Introduction
Mutations in BRCA1 or BRCA2 genes are considered the most prevalent cause of hereditary breast and ovarian cancer syndrome (HBOC), although other genes also explain this kind of affection. Since 2014, the Uruguayan Collaborative Group (UCG), a nonprofit organization is devoted to the registry, diagnosis, management and research of hereditary cancer, has been recruiting high-risk family groups with HBOC.

Objective: To report about pathogenic variants in BRCA and non-BRCA genes detected in Uruguay high-risk for HBOC population.

Methodology
From the UCG registry, 592 non-related are defined as HBOC-high risk population following the National Comprehensive Cancer Network 2018 guidelines. Selected probands for genetic testing signed informed consent prior to obtain saliva or blood samples. Different approaches for searching gene mutations have been employed. At first, Next Generation Sequencing of BRCA1 and BRCA2, then large rearrangements detection methods were used, and lately multigene panels have been employed.

Results
330 (56%) HBOC-high risk, non-related probands were tested, 56 were found positives and 49 different pathogenic variants identified. BRCA1-2 accounted for 31 (66%) pathogenic mutations (14 BRCA1 and 17 BRCA2) while mutations in non-BRCA genes were: PALB2(3), ATM(1), CHEK2(3), BARD1(3), TP53(6), CHD1(1), NBN(1).

Conclusion
Even though only HBOC high risk probands were selected, a relatively high proportion of non-BRCA genes presented with pathogenic variants. Although multigene panels can give unexpected and uninformative results, when used with thoughtfulness, they can be a valuable tool capable of diagnose beyond the traditional boundaries of BRCA genes. Despite technological improvements, a high number of families with no molecular diagnosis still remains. Since the role of constitutive epimutations in cancer development can be underestimated, future approaches will include a methylation screening.
