Abstract:

In recent years, the green synthesis of gold (GNPs) and silver (SNPs) nanoparticles has gained great interest among chemists and researchers. The present study reports an eco-friendly, cost-effective, rapid and easy method for the synthesis of gold and silver nanoparticles using the seed extract of \textit{Embelia ribes} (SEEr) as capping and reducing agent. The synthesized GNPs and SNPs were characterized using the following techniques: UV-Vis spectroscopy, DLS, HR-TEM, FT-IR and XRD. The free radical scavenging potential of GNPs and SNPs was measured by DPPH assay and Phosphomolybdenum assay. Further, the antimicrobial activity against two microorganisms were tested using disc diffusion method and cytotoxicity of GNPs and SNPs was determined against MCF-7 cell lines at different concentrations by MTT assay. Both the GNPs and SNPs prepared from \textit{Embelia ribes} comparatively showed promising results thereby proving their clinical importance.

Keywords: Green synthesis, Gold nanoparticles, Silver nanoparticles, Seed extract, Embelia ribes

**Experimental**

**Materials**

All chemicals used in this experiment were of high level purity and obtained from Sigma chemicals (Bangalore, India). Silver nitrate salts, Chlorauric acid salts, MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide) invitrogen, USA. Acridine orange were obtained from Sigma, USA. All other fine chemicals were obtained from Sigma–Aldrich, St. Louis.

*Synthesis of silver and gold nanoparticles from plant extract*

The seeds of *Embelia ribes* (family: Myrsinaceae) plants were harvested from Vellore district of Tamil Nadu. The seed extract was first prepared by mixing 1.25 gm of dried powder with 50 mL of deionized water suspended in 250 mL conical flask and kept for boiling at 60°C for 1 hour. A constant volume of 1 mL of the prepared seed extract was taken in ten different boiling tubes, followed which 1x10^{-3} M AgNO₃ and 1x10^{-4} M HAuCl₄ was added in 0.1 to 1 mL range in two different sets respectively and the final volume of the reaction was made up to 5 mL with deionized water. The stability of gold and silver nanoparticles were checked by varying the pH ranging from 7 to 13 (data not shown). The optimum synthetic conditions were determined based on their characterization.

*Characterization studies of synthesized gold and silver nanoparticles using seed extract.*

The absorbance of SEEr-GNPs and -SNPs were characterized using UV-Visible spectrophotometer UV-1601 (Shimadzu Corporation, Japan). The nanoparticle solution in the reaction tube showing distinct characteristic peak was considered as optimum concentration, respectively. The hydrodynamic size of SEEr-GNPs and -SNPs was analyzed using particle size analyzer (Malvern NanoZS). Fourier transform infra-red spectroscopy analysis was carried out to identify the functional moiety responsible for the reduction of gold and silver ions to form nanoparticles. The FT-IR range was set between 500 – 4000 cm⁻¹. The X-ray diffraction was used to investigate the crystal structure of seed extract based synthesized gold nanoparticles. The
sample was ground and pressed in the sample holder to get a smooth plane surface and the diffraction pattern was observed over 2θ range of 30°-120°. High resolution Transmission Electron Microscopy (HR-TEM) analysis was obtained with TEM-D950 TECHNAI G2-S-TWIN (FEI Company). The sample was added to the carbon-coated copper grid and dried at room temperature.

**Antioxidant activity**

**DPPH (2, 2-diphenyl-1-picrylhydrazyl) assay**

The free radical scavenging activity of the extract, SEEr-GNPs and SEEr-SNPs was determined using DPPH assay (Wang et al. 2008). The dilution series of the test solutions (10-100 µg/mL) were incubated with freshly prepared DPPH solution in methanol (0.004% w/v). The reaction mixture was mixed vigorously and allowed to stand for 30 mins at room temperature. The change in the absorbance was measured photometrically at 517 nm using a Lambda 25 UV-Vis (Perkin Elmer, USA) spectrophotometer. The decrease in the absorbance denotes higher DPPH free radical scavenging activity. The procedure was repeated thrice to get triplicate values. Ascorbic acid dissolved in distilled water was used as reference standard. 95% of methanol was used as blank reagent. The ability of the sample to scavenge DPPH radical was calculated using the following formula. 

\[
\frac{(Ac - At)}{Ac} \times 100
\]

where Ac represents the absorbance of the control and At represents the absorbance of the test samples.

**Phosphomolybdenum assay**

The antioxidant activity of samples was evaluated by the green phosphomolybdenum complex formation according to the method of Prieto et al (1999). An aliquot of 100µL of sample solution was combined with 1 mL of reagent solution (0.6M sulphuric acid, 28mM sodium phosphate and 4mM ammonium molybdate) in a 4 mL vial. The vials were capped and incubated in a water bath at 95°C for 90 min. After the samples had cooled to room temperature, the absorbance of the mixture was measured at 695 nm against a blank. The results reported are mean values expressed as %PRP (Phosphomolybdenum Reducing Potential). Percent inhibition was
calculated by the following formula, \( \text{PRP} \) (\%) = \((1-\text{At}/\text{Ac})\times100\), where \( \text{At} \) refers to the absorbance of the test sample, \( \text{Ac} \) refers to the absorbance of the control.

**MTT Assay**

Cell viability was measured with the conventional MTT reduction assay. Briefly, MCF-7 cells were seeded at a density of \(5\times10^3\) cells/well in 96-well plates for 24 h in 200 µL of RPMI with 10% FBS. Then culture supernatant was removed and various concentrations (0.11–100µg/mL) of test sample (SEEr-GNPs and -SNPs) was added and incubated for 48 h. After treatment cells were incubated with MTT (10µL, 5mg/mL) at 37 °C for 4 h and then with DMSO at room temperature for 1 h. The plates were read at 595nm on a scanning multi-well spectrophotometer. Data represented the mean values for six independent experiments (Evelyn et al. 2012).

\[
\text{Cell viability (\%) = Mean OD/Control OD x 100}
\]

**Antibacterial Activity**

The antibacterial activity of SEEr-GNPs and -SNPs were determined using two bacterial cultures viz. Escherichia coli and Staphylococcus aureus by well diffusion method. The different concentrations of the test sample used were (250µg/mL, 500 µg/mL, 750 µg/mL and 1000 µg/mL) added in the wells made on the nutrient agar plate. The antibiotic Tetracycline was used as standard. The plates were incubated at 37°C for 24-48hrs. After incubation, the zone of inhibition was measured to determine the extent of antibacterial activity.

**Statistical analysis**

The data was expressed in percent inhibition with respect to control. All the tests were performed in triplicates and data expressed are as mean ±SD.
