Combined de sizing and scouring of cotton fabric using xylanase enzyme

Abstract

The textile materials used for healthcare products should be hygiene, free from impurities and chemical content. In order to reduce the hazards caused by the chemical effluents, use of enzymes in the pretreatment of textiles is the only alternative method. In this research, the effect of mode of treatment of xylanase enzyme and its process conditions such as enzyme concentration (1.5, 2 and 2.5g/l), temperature (40, 50 and 60˚C) and time (60, 90 and 120 min) on the combined de sizing and scouring of cotton fabric were studied. The cotton fabric was assessed by measuring the weight loss and water absorbency. It was found from the results that the fabric treated with xylanase enzyme, buffer and acetic acid has shown optimum weight loss and absorbency. The fabric sample treated at 1.5g/l, 50˚C, and 90 min has shown better absorbency levels.

Keywords: xylanase, scouring, de-sizing, absorbency, weight loss

Introduction

Natural fibers consist of natural and added impurities. Cotton being called as the king of fibers has wide application in many fields. Impurities present in cotton are removed by pre-treatment process in order to make it ready for dyeing or printing. It consists of various processes from singeing to bleaching. Pollution due to disposal of chemicals is a major threat for environment in textile processing. As technology improved, development has been made in these processes which had made it more effective and eco-friendly. Among the development from usage of chemicals, enzymes are used for textile pretreatment. The usage of enzymes has proved to be more eco-friendly, water and energy saving when compared to other methods of pretreatment. Enzyme usage has also proved to increase the product quality.

Much research has been directed to replace this chemical process by a more environmental friendly enzyme-based one.2,3 Dengni reported that increase in cutinase concentration increases the water absorbency of cotton fabrics.4 Shafie stated that the cotton fabric treated with cellulase enzyme in one step bio-scouring and peracetic acid bleaching has shown excellent wettability.5 Eren reported that the advantages of one bath enzymatic de sizing and bleaching of cotton fabric is less auxiliary demand, energy and water savings and low environmental impact when compared to the conventional preparatory process.6

Xylanase is an enzyme which is also being used in the textile wet processing and have been reported mainly from bacteria,7-9 fungi,1 actinomycetes10 and yeast.11,12 Xylanase treatment could lead to hydrolysis of the tiny fibers that attached the seed-coat fragments to the fabric. This could make the residual seed-coat fragments more accessible to chemicals, thereby reducing the consumption of hydrogen peroxide in the consecutive chemical bleaching step.12 Even though, the xylanase enzymes are used in textile wet processing, no study available on combined preparatory process in textile wet processing. Hence an attempt is made in this work to investigate the effect of mode of treatment of xylanase enzyme and also the influence of processing conditions of combined de sizing and scouring on the weight loss and water absorbency of cotton fabric.

Materials and methods

Materials

Woven cotton fabric of thread density 60X60, linear density of 40X40 Ne, and 150GSM was used for the study. The commercially available xylanase (bacterial base) enzyme was used for de sizing and scouring of cotton.

Methods

The grey cotton fabric was de-sized and scoured with different modes of pretreatment (enzyme, enzyme + buffer, enzyme + wetting oil, and enzyme + wetting oil + acetic acid) to study the effect of mode of treatment on cotton fabric. The enzyme concentration of 2g/l and the liquor ratio of 1:20 were used in all the processes.

Further to study the effect of enzyme concentration, time and temperature, the cotton fabric was treated with different processing conditions which are given in Table 1. The cotton fabric was treated in agitated system with a liquor ratio of 1:20 at pH 5. In the agitation system, agitation speed was set to 50 rpm during the bio-treatment. After enzymatic treatment, the fabrics were washed twice in boiling distilled water to deactivate the enzyme and to remove the sizing chemicals.

Testing

Weight loss %

The weight of the cotton sample before and after the enzyme treatment was taken in electronic balance. The weight loss percentage of cotton fabric is determined by using the following formula.

\[ \text{Weight Loss} = \left(\frac{W_1 - W_2}{W_1}\right) \times 100 \]

Where W1 and W2 are the weights of the fabric before and after treatment

Water absorbency: The absorbency test was carried out using the AATCC Test-79. The wetting time of fabric is measured to know the performance of enzyme treatment on cotton. It was measured by simple detection of the time required to absorb one drop (10μl)
Combined de sizing and scouring of cotton fabric using xylanase enzyme

of water. Average values of five determinations were taken. Sample is placed in an embroidery hoop with all creases out of it. A burette dispenses a drop of water onto the surface of the fabric from a distance of 9.5mm below the burette. Time is recorded until the water drop absorbs completely.13-17

Table 1 The different processing conditions for combined de-sizing and scouring

| Sample no | Enzyme concentration (g/l) | Time (min) | Temperature (˚C) |
|-----------|---------------------------|------------|------------------|
| S1        | 1.5                       | 60         | 40               |
| S2        | 90                        | 50         |                  |
| S3        | 120                       | 60         |                  |
| S4        | 60                        | 40         |                  |
| S5        | 2                         | 90         | 50               |
| S6        | 60                        | 50         |                  |
| S7        | 120                       | 40         |                  |
| S8        | 2.5                       | 90         | 50               |
| S9        | 120                       | 60         |                  |

Results and discussion

Effect of mode of pre-treatment on weight loss % and absorbency of cotton fabric

Figure 1 depicts the effect of mode of pretreatment on the weight loss percentage of the cotton fabric. It is observed that enzyme + wetting oil + acetic acid treated and enzyme treated samples have shown 8% weight loss. The enzyme + wetting oil treated fabric have shown a weight loss of 7%. The minimum weight loss of 4% is observed in enzyme + buffer treated fabric sample.

Figure 2 Influence of mode of pretreatment on (b) Absorbency.

Effect on varying the enzyme concentration, time and temperature on weight loss % and absorbency

The Figure 3 illustrates the influence of varying enzyme concentration, time and temperature on weight loss percentage of cotton fabric. It is clear from the figure that weight loss value of the fabrics seemed to increase with an increase in the treatment time and temperature. Increase in reaction time and agitation also results in increase in weight loss percentage of the fabric.11 It is also observed that the weight loss percentage of cotton is higher initially in the samples treated at 2g/l enzyme concentration.

Figure 3 Influence of varying enzyme concentration, time and temperature on weight loss (%) (a) 1.5g/l (b) 2g/l (c) 3g/l.

Further it is also found that the wetting time values of fabrics obtained after 90min of treatment were significantly lower to that of fabrics obtained after 60min of treatment whereas further increasing the treatment time from 60 to 120min did not result in much lowering of the wetting time.10

Figure 4 illustrates the influence of varying enzyme concentration, time and temperature on absorbency of cotton fabric. It is noted that the sample S2 with the enzyme concentration of 1.5g/l, time 90min and temperature 50˚C has given better absorbency in 4sec. The
wetting time of enzymatic pretreated fabrics is better than chemically scoured fabrics.

**Conclusion**

The effect of xylanase enzyme on the pretreatment of cotton fabric is investigated by varying mode of application and process conditions of combined desizing and scouring. It is observed from the results that the fabric treated with xylanase enzyme, buffer and acetic acid has shown optimum weight loss and absorbency. Optimum conditions for the treatment of xylanase enzyme on the cotton fabric are found at 1.5g/l, 50˚C, and 90min in the combined desizing and scouring.
