**Abstract**

Integrins - β are highly conserved pleiotropic cytokine. In this study, we cloned the full-length cDNA sequence of yellow catfish *Pelteobagrus fulvidraco* integrin - β1 and integrin - β3 gene. The Integrin - β1 cDNA is 2816 bp in length and encodes a protein of 461 amino acids. Integrin - β3 cDNA is 1713 bp in length and encodes 479 amino acids. Integrins - β were classified strictly with the same type of proteins by phylogenetic analysis. *Stegastes partitus* integrins - β was classified on the same phylogenetic branch compared with other fish. Tissue transcription profile analysis indicated that, in the healthy *P. fulvidraco*, integrins - β mRNA was predominantly expressed in the liver and brain, follow by gill and spleen. The *P. fulvidraco* integrins - β shares high homology with the Cypriniformes *Danio rerio* (83% -93%). Expression of the two Integrins - β transcripts showed significant expression changes in 4 h after infection with *Flavobacterium columnare*, which has modulation of expression continuing up to 3 d following pathogen exposure. Both of the integrin - β genes were significantly up-regulated at 24 h in spleen and liver after infection tissue. Integrin - β3 showed the most sensitive to *F. columnare*, suppressing expression - 6.34 - fold at 24h. This informations elucidates the functions of individual integrins - β genes in regards to pathogen recognition, binding, and their larger immune context.

**Keywords:** Integrins β; *Pelteobagrus fulvidraco*; Gene clone

**Introduction**

Integrins are mediating cell - cell, cell - matrix, cytoplasmic extracellular matrix interactions and bidirectional signal transduction between the cytosol, which contain type α and β subunits bidirectional signal non - covalent binding of formed between the transduced cell surface heterodimer [1]. Integrins contain 24 different α and β heterodimers receptors [2]. The expression profile of integrins on cancer cells and the composition and organization of extracellular matrix (ECM) of the tumor stroma are major factors in therapy resistance, metastasis and cancer development [3]. Collagen is the most abundant ECM protein in vertebrate organisms, forming the framework of connective tissues and soft interstitial matrices (such as the bone marrow), and is also a critical matrix of the tumor microenvironment [4].

Integrins - β1, associate with 12 different a subunits, is the largest sub - family of integrins [2]. Integrin - β1, as a major collagen receptor, is widely expressed and known to promote cell migration and control tissue homeostasis. Integrin - β1 can either inhibit or promote the cancer cells dissemination process and cancer metastasis regulator [5]. Integrin - β3 plays an important role in a number of physiological and pathological processes such as angiogenesis, tumor invasion and metastasis, and its expression is correlated with disease progression in various tumor types [6,7].

For aquatic animals, the study on integrins - β is few, for wexple, integrin - β subunits (β - integrin) in shrimps involved in WSSV infection [8]. In order to adapt the continuous improvement of people’s living standard, the scale of aquaculture presents the increasing trend which lead to the farmed animal disease outbreaks [9]. Yellow catfish *Pelteobagrus fulvidraco*, an omnivorous freshwater fish, is considered as a good candidate for freshwater aquaculture in China for its tasty meat and high market value [10]. Yellow catfish *P. fulvidraco* integrins - β genes and the distribution of mRNA expression have not been reported.

In the study, we obtained the full-length cDNA sequence of integrinβ from Yellow catfish, and further make the necessary sequence analysis, tissue expression analyzed the putative proteins encoded by the gene using bioinformatic approaches. The results of our study provided the basic information to identify the function of integrins - β and to study the molecular mechanism of Yellow catfish *P. Fulvidraco*.

**Materials and Methods**

**RNA isolation**

The *P. fulvidraco* were obtained from the Chinese Academy of Fishery Sciences Pelteobagrus sp. Breeding Engineering Center. All yellow catfish were 1 year old, 31.6±2.8 g weight, 14.5±3.4 cm length. Total RNA of the yellow catfish was extracted with Trizol reagent (Invitrogen, China) following the manufacturer’s instructions. The total RNA concentration was determined by measuring the absorbance at OD260. RNA integrity was checked by electrophoresis. The total RNA was reverse-transcribed into cDNA using the aM-MLV RTase cDNA Synthesis Kit (TaKaRa, Japan). For cloning and expression analysis, various tissue samples, including the gill, blood, muscle, gonad, liver, brain, spleen, kidney, heart, intestine from male and Female, were immediately collected and frozen in liquid nitrogen until RNA isolation.

Integrins - β3 cloning

Total RNA was extracted from the P. Fulvidraco tissues including the gill, blood, muscle, gonad, liver, brain, spleen, kidney, heart and intestine using a number for R8047A RT Reagent Kit (TaKaRa, Japan) according to the manufacturer's instructions. The cDNA was used as the template to amplify the gill, blood, muscle, gonad, liver, brain, spleen, kidney, heart and intestine was stored at -20°C. According to Ictalurus Punetansus in Genbank madtoms integrins β (serial number FD303964 and FD290690), we designed the PCR primers β 1 - F1, β 1 - R1, β 2 - F1 and β 2 - R1 for integrins cloning. (Table 1). After the sequence by Heilongjiang River Fisheries Research Institute of products research, development of genomics and molecular breeding research for yellow catfish are found in 99% of similarity in the method of the transcriptome gene sequence and gene sequence designed primers. For integrins cloning, PCR primers β 1 - F1, β 1 - R1, β 2 - F1 and β 2 - R1 were designed (Table 1).

The PCR conditions were as follows: 94°C for 4 min, followed by 35 cycles of amplification (94°C for 1 min, 56°C for 1 min, and 72°C for 1 min 30 s), and 72°C for 10 min. The 25 μL reaction volume contained 50 ng genomic DNA using an Agarose Gel DNA Purification Kit ver. 1.0 (TaKaRa, Japan). In the first challenge, the P. fulvidraco, with an average body weight of 28.6 g and average body length of 11.92 cm, kept at 26°C in a flow - through system utilizing heated. Sterile water were used for the challenge. The fish were divided into two groups: (1) F. columnare challenge group (immersed with the dose of 3 ml of 100 CFU ml−1 of F. columnare, Japan); (2) control group (without bacteria). To inoculate the fish in the challenge, a single colony of F. columnare was isolated and cultured in BHI broth at 28°C overnight. The bacterial culture was diluted with PBS (pH 7.4), then 1×10⁶ CFU of bacteria in 200 μl PBS were injected intraperitoneally into the channel P. fulvidraco. The spleen and gill tissues from 60 fish (three pools of 15 fish each) at 4h,
24h, 48h and 3d after *F. Columnare* treatment were isolated for RNA extraction, respectively. Corresponding, uninfected control samples were taken at each time interval.

**Statistical analysis**

All data obtained from the qRT-PCR were calculated to the value of $2^{-\Delta\Delta CT}$ and differences were evaluated statistically using a t-test in SPSS 20.0 software (IBM, Chicago, USA). The relative expression levels of each gene in different tissues were calculated to the $2^{-\Delta\Delta CT}$ of the mean and the standard error (SE) from the three replications. Statistical significance was set with a P value less than 0.01.

**Results**

**Phylogenetic analysis of gene integrins - β**

A phylogenetic tree was constructed based on the amino acid sequences of selected integrins - β using the neighbour-joining (NJ) method (Figures 1 and 2). This phylogenetic tree was analyzed by
Figure 2: Phylogenetic tree of integrin-β amino acid sequences in P. fulvidraco from different species by maximum likelihood (NJ) analyses. The numbers on the branches are bootstrap values for NJ.

MEGA4 using the Neighbor - Joining method with 1000 bootstrap replicates and the evolutionary distances were calculated using the Poisson correction method. The homology similarity of integrins - β (integrins - β1 and integrins - β3) were 83% ~ 87% compared with Cypriniformes Danio rerio (Figure 1). The figure shows the homology similarity of integrins - β was 58% compared with integrins - β3. The homology similarity of integrins - β1 was 90% compared with Ictalurus Punetatus. The homology similarity of integrins - β1 was 79% compared with Esox lucius. The homology similarity of integrins - β3 was 81% compared with Larimichthys crocea. The homology similarity of integrins - β3 was 82% compared with Poecilia formosa.

Tissue expression of integrins - β genes

Quantitative real - time PCR was performed to determine the tissue distribution of integrins - β gene expression in both male and female P. fulvidraco. P. fulvidraco integrins - β (integrin - β1 and integrin - β3) were mainly expressed in gut, blood, gonads, brain, liver, kidney, spleen, gills, muscle and heart. Integrin - β genes expression levels in male gonads and gut were higher than those in female. Integrin - β genes expression levels in female liver were higher than those in males P. fulvidraco. Integrin - β1 and integrin - β3 gene expression level in male and females brain and kidney were highest (Figure 3).

Expression of integrin - β after infection of F. Columnare

The transcript expression levels of the two integrins - β genes after bacterial infection with F. columnare in liver and gill tissues (Figure 4) was also examined using qRT - PCR. All integrin - β genes were significantly up - regulated at 24 h after columnaris infection in spleen tissue. Integrin - β1 showed the most sensitive response to infection, suppressing expression - 6.34 - fold at 24h (Figure 4). In gill, Integrin - β1 and Integrin - β3 were significantly up - regulated at 24 h after infection.

Discussion

In this study, we firstly get the CDNA of P. fulvidraco integrins - β gene. Through sequence analysis, it can be seen that yellow catfish P. fulvidraco integrin - β gene encodes a protein with high homology to other integrins - β fishes. This implied that the integrins - β genes were highly conserved in some fishes and the yellow catfish integrins - β gene might have similar functions as the integrins - β genes of other fishes. It can be also found that the yellow catfish integrins - β protein does not show complete identity to other fishes.

Integrin - β inhibitors can inhibit the occurrence of bone tumor by inhibiting the expression of osteoclast activity and tumor derived factors [12]. In colorectal cancer, integrin - β1 mediated ERK activation has been shown to regulate lineage commitment in multipotent human colorectal cancer cells [13]. Integrin - β1 can also inhibit differentiation and promote a stem cell - like phenotype in human colorectal carcinoma cells, which was associated with formation and expression of stem cell markers Bmi1 and CD133 [14]. P. fulvidraco integrins - β and ERK contact with colorectal cancer cells of innate immune strategies system has certain help by an as yet undisclosed mechanism(s). Currently in human clinical trials, there are alpha2 and beta3 integrin inhibitors for the treatment of a variety of cancer [15]. Yellow catfish P. fulvidraco integrins - β3 thus blocking cell sensing this influence bone metastasis ability of tumor cells to transition a new therapeutic opportunity. Importantly, For future research and development, yellow catfish integrins - β inhibitors would be used to other diseases in the clinic, and may be a promising way to prevent the progression of bone tumors.
In mouse model, integrin-β1 cells constitute the basal layer and p75 neurotrophin receptor (p75NTR) cells constitute the undercoat structure. Interestingly, in human patients with chronic skin ulcers, p75NTR+ cells were significantly decreased. These results indicate that integrin-β1 cells may play an important role in wound healing process [16]. It may be a chronic skin ulcers catfish of new therapeutic targets. Integrin-β1 involved in the wound healing process: inflammation, collagen synthesis stimulating angiogenesis, fibroblast proliferation and deposition and remodeling of the extracellular matrix [17]. The subsequent yellow catfish integrin-β1 research, such as constitute the basal layer cells constitute the undercoat structure, would reduce the yellow catfish body skin breakdown and mention rapid healing capabilities. The suitable explanation for this under current conditions is that at the same time those biological activities related to the mRNA expression of yellow catfish integrins-β gene were presented diversely in different tissues. To further understand the function of this novel gene, more research based on these primary results is needed.

Integrins-β Genes have a putative role domain and a conserved. However, in kidney and gill, the increase in expression of integrins-β was following F. columnare stimulation, implying a tissue-specific modulation of expression. It should be noted that the two regulatory regions of the integrins-β exhibited different to previously identified integrin-β1 and integrin-β2 sequences.

In summary, based on the sequence from cDNA of the integrins-β belong to integrin family in P. fulvidraco, we analyzed the sequence, detected tissue transcription profile analysis, and predicted and analyzed the putative protein using bioinformatics tools. These results of our study will pave the way to further elucidate the functions of individual integrins-β genes in regards to pathogen recognition, binding, and their larger immune context.
