Computationally Efficient Robust Model Predictive Control for Uncertain System Using Causal State-Feedback Parameterization

Anastasis Georgiou, Member, IEEE, Furqan Tahir, Imad M. Jaimoukha, and Simos A. Evangelou, Senior Member, IEEE

Abstract—This article investigates the problem of robust model predictive control (RMPC) of linear-time-invariant discrete-time systems subject to structured uncertainty and bounded disturbances. Typically, the constrained RMPC problem with state-feedback parameterizations is nonlinear (and nonconvex) with a prohibitively high computational burden for online implementation. To remedy this, a novel approach is proposed to linearize the state-feedback RMPC problem, with minimal conservatism, through the use of semidefinite relaxation techniques. The proposed algorithm computes the state-feedback gain and perturbation online by solving a linear matrix inequality optimization that, in comparison to other schemes in the literature, is shown to have a substantially reduced computational burden without adversely affecting the tracking performance of the controller. Additionally, an offline strategy that provides initial feasibility on the RMPC problem is presented. The effectiveness of the proposed scheme is demonstrated through numerical examples from the literature.

Index Terms—Elimination lemma, linear matrix inequalities, robust model predictive control (RMPC), semidefinite relaxation, state-feedback control, uncertain systems.

I. INTRODUCTION

Model predictive control (MPC) is a class of receding horizon algorithms in which the current control action is computed by solving online, at each sampling instant, a constrained optimization problem [1], [2], [3]. MPC is widely used in industry [4] due to its ability to handle multivariable processes and to explicitly consider physical constraints.

Several MPC schemes have been proposed for deterministic systems [5], [6]. However, uncertainty, in the form of disturbances, state estimation error, plant-model mismatch, and robust constraint satisfaction and stability remain active areas of research [7], [8], [9], [10], [11], [12].

The family of MPC algorithms, which explicitly take account of uncertainties/disturbances whilst guaranteeing constraint satisfaction and performance is referred to as robust MPC (RMPC). An obvious approach to extend MPC for uncertain systems is to solve an open-loop optimal control problem. Whilst computationally attractive, this may lead to infeasibility and suboptimality [5]. A more effective method is to consider a state-feedback control law, as shown in [10], where state-feedback parameterization have been used in RMPC for system subject to additive disturbances. By considering future inputs as linear/nonlinear functions of current and future predicted states, feedback RMPC schemes mitigate the effect of uncertainties whilst potentially avoiding the infeasibility issues. The three main types of RMPC schemes include min–max, tube, and linear matrix inequality (LMI)-based MPC schemes. The min–max MPC method computes the optimal control sequence that satisfies the constraints and steers the system to a robust positively invariant set whilst guaranteeing worst-case uncertainty [7], [8]. The second approach, which has received significant attention, is tube-MPC (TMPC) [3], [9], [13], [14]. Instead of considering worst-case uncertainty, these methods first predict a nominal system trajectory and then guarantee that all possible closed-loop state trajectories lie inside a “tube” around the nominal trajectory, where the tube is computed offline using the uncertainty bounds.

The third approach uses semidefinite programming to compute, online, an optimal control sequence by solving an LMI optimization problem [15], [16], [17], [18]. The advantages of the LMI-based method are the explicit incorporation of uncertainty and the polynomial time required for its solution, which, though still high compared with min–max and TMPC methods, allows online implementation [19] for certain problems. Further details around the implementation issues and tradeoffs were reviewed and quantified in [20].

In the work described earlier, the focus was on systems involving only disturbances or scalar uncertainties. A generalization to systems with structured uncertainties and disturbances was proposed in TMPC format in [21], [22], and [23] and in ongoing research on system level synthesis [24], [25]. An LMI-based RMPC approach was proposed in [26] and used in an industrial directional drilling application in [27]. In this scheme, the state-feedback gain and control perturbation are computed online whilst avoiding the nonconvexity issues. Although this approach shows the significant performance improvement, it introduces a large online computational burden, which makes it unsuitable for fast dynamical systems. To solve this problem, an extension to [26] is proposed here that has a substantially reduced online computational burden without sacrificing performance.

The contributions of this work are summarized as follows. First, a new LMI-based RMPC scheme is proposed in Section II for systems subject to structured uncertainty and disturbances. The feedback gain and control perturbation are considered as decision variables whilst nonlinearities are circumvented using a novel linearization procedure (see Section III). This substantially reduces the online computations, while it improves performance due to its less restrictive nature (see Remark 2) without reducing the feasibility region. Second, to reduce the online computation time further, an extension is proposed in Section IV, which derives a single LMI sufficient condition for all the constraints. Lastly, this improves the scalability of the algorithm. Section V proposes...
an offline initialization strategy to guarantee initial feasibility for the control problem.

The rest of this article is organized as follows. In Section II, the uncertain system is described and the RMPC problem is formulated, while nonlinearities and computational intractability are highlighted. In Section III, an LMI solution based on the proposed linearization procedure is provided, with the disturbance recast as uncertainty. A computationally efficient approach for handling constraints by solving a single LMI is presented in Section IV. Section V presents a feasibility analysis and an offline policy to guarantee initial feasibility. Simulation results for case studies taken from the literature are presented in VI, where the effectiveness of the proposed controller in terms of tracking performance, robustness, and computational burden is highlighted and compared with current RMPC methods. Finally, a summary is given in Section VII, along with potential future research directions. The \( \mathbb{R} \) denotes the set of real numbers, \( \mathbb{R}^n \) denotes the space of \( n \times n \)-dimensional real (column) vectors, \( \mathbb{R}^{n \times m} \) denotes the space of \( n \times m \) real matrices, and \( \mathbb{D}^n \) denotes the space of diagonal matrices in \( \mathbb{R}^{n \times n} \). For \( A \in \mathbb{R}^{n \times m} \), \( A^T \) denotes the transpose of \( A \). For \( A \in \mathbb{R}^{n \times n} \), \( \mathcal{H}(A) := A + A^T \). For \( A = A^T \) we write \( A \succeq 0 \) (\( A \preceq 0 \)) if \( A \) is positive (negative) semidefinite and \( A \succ 0 \) (\( A \prec 0 \)) if \( A \) is positive (negative) definite. For \( x, y \in \mathbb{R}^n \), the inequality \( x < y \) (similarly: \( x \leq y \) and \( x \geq y \)) is interpreted element-wise. \( I_q \) denotes the \( q \times q \) identity matrix with the subscript omitted when it can be inferred from the context. For matrices \( A_1, \ldots, A_m \), \( \text{diag}(A_1, \ldots, A_m) \) denotes a block diagonal matrix whose \( i \)-th diagonal block is \( A_i \). The symbol \( \epsilon_i \) denotes the \( i \)-th column of the identity matrix of appropriate dimension. If \( \mathcal{U} \subseteq \mathbb{R}^{p \times q} \) is a subspace, then \( \mathcal{U} = \{ U \in \mathbb{U} : U U^T \preceq I \} \) denotes the unit ball of \( \mathcal{U} \). The Schur complement argument refers to the result that if \( C > 0 \) then \( \begin{bmatrix} A & B \\ B^T & C \end{bmatrix} \succeq 0 \) if and only if \( \begin{bmatrix} A & B \\ B^T & C \end{bmatrix} \succeq 0 \), where \( \ast \) denotes a term inferred from symmetry. To deal with uncertainty, we use the following lemma based on [28] and the use of a Schur complement argument.

**Lemma 1:** Let \( H_{11} = H_{11}^T \), \( H_{12}, H_{21} \), and \( H_{22} \) be real matrices. Let \( \tilde{\Delta} \) be a linear subspace and define the linear subspace

\[
\tilde{\Psi} = \{(S, R, G) : S, R > 0, S \Delta = \Delta R, \mathcal{H}(\Delta G) = 0 \forall \Delta \in \tilde{\Delta} \}.
\]

Then, \( \text{det}(I - H_{22} \Delta) \neq 0 \) and \( H_{11} + \mathcal{H}(H_{12} \Delta(I - H_{22} \Delta)^{-1}) H_{21} \succ 0 \) for every \( \Delta \in \tilde{\Psi} \) if there exists \( (S, R, G) \in \tilde{\Psi} \) such that:

\[
\begin{bmatrix}
H_{11} & H_{12} G^T \\
R & \mathcal{H}(H_{22} G^T) & H_{22} S
\end{bmatrix} \succ 0. \tag{2}
\]

We refer to the S-procedure. This is used to derive sufficient LMI conditions for the sign definiteness of a quadratic function on a set described by quadratic inequality constraints [29].

**II. PROBLEM STATEMENT**

In this section, the system description including control dynamics, constraints, and cost signal are first provided. Then, the RMPC control problem is presented through recasting disturbance as uncertainty as shown in [26]. Lastly, the difficulties to solve this optimization problem are highlighted.

**A. System Description**

The following linear discrete-time system, subject to bounded disturbances and norm-bounded structured uncertainty, is considered (see, e.g., [15]):

\[
\begin{bmatrix}
q_k \\
f_k \\
z_k
\end{bmatrix} = \begin{bmatrix}
A & B_u & B_p \\
C_q & D_{qu} & 0 \\
C_f & D_{fu} & 0
\end{bmatrix} \begin{bmatrix}
x_k \\
u_k
\end{bmatrix} + \begin{bmatrix}
0 \\
0 \\
0
\end{bmatrix}, p_k = \Delta q_k,
\]

\[
\begin{bmatrix}
q_N \\
f_N \\
z_N
\end{bmatrix} = \begin{bmatrix}
\hat{C}_q & 0 \\
\hat{C}_f & \hat{D}_{fp} \\
\hat{C}_z & \hat{D}_{zp}
\end{bmatrix} \begin{bmatrix}
x_N \\
p_N
\end{bmatrix}, p_N = \Delta_N q_N.
\]  

(3)

where \( x_k \in \mathbb{R}^n \), \( u_k \in \mathbb{R}^{n_u} \), \( w_k \in \mathbb{R}^{n_w} \), \( f_k \in \mathbb{R}^{n_f} \), \( z_k \in \mathbb{R}^{n_z} \), \( p_k \in \mathbb{R}^{n_p} \), and \( q_k \in \mathbb{R}^{n_q} \) are the state, input, disturbance, constraint, cost, and input and output uncertainty vectors, respectively, with \( k \in \mathbb{N} := \{0, 1, \ldots, N - 1\} \), where \( N \) is the horizon length. It is assumed that the state \( x_k \) is measurable. Note that the description includes terminal cost and state constraints to ensure closed-loop stability [1]. The symbols in capital letters denote coefficient matrices with the dimensions indicated for ease of reference. Furthermore, \( \Delta_k \in \mathcal{B} \Delta \) where \( \Delta \subseteq \mathbb{R}^{n \times n} \) is a subspace that captures the uncertainty structure. Note that we allow uncertainty in all the data including the constraints and the cost signal. Finally, the disturbance \( w_k \) is assumed to belong to the set \( \mathcal{W} \) \( \subseteq \mathbb{R}^{n_w} : -d_k \leq w_k \leq d_k \), where \( d_k > 0 \) is given.

**B. Algebraic Formulation**

To simplify the presentation, we reparameterize the disturbance as uncertainty by redefining \( \mathcal{W}_k := \{ \Delta_k \hat{d}_k : \Delta_k \in \mathcal{B} \Delta \} \), where \( \Delta := \Delta \mathcal{W} \) \( \in \mathbb{D}^n \) and

\[
\begin{bmatrix}
B_u \\
B_p
\end{bmatrix}, C_q := \begin{bmatrix}
C_q \\
0
\end{bmatrix}, D_{qu} := \begin{bmatrix}
D_{qu} \\
0
\end{bmatrix},
\]

\[
\hat{d}_k := \begin{bmatrix} 0 \\ \hat{d}_k \end{bmatrix}, p_k := \begin{bmatrix} p_k \\ w_k \end{bmatrix}
\]

\( q_k := C_q x_k + D_{qu} u_k + \hat{d}_k \) and \( n_u := n_q + n_w, n_q := n_q + n_w \). The vector \( \hat{d}_k \) is assumed to be given and defines the reference trajectory. The constraint and terminal constraint signals are defined by \( \hat{f}_k \) and \( \hat{z}_k \), respectively, and are assumed to be known. They are chosen to satisfy polytopic constraints on the input and state signals, and terminal state signals, respectively. The only assumption that is imposed here is that the terminal constraints defined by \( \hat{z}_k \) are within a polytopic control invariant set [30], which can be used to derive condition for recursive feasibility on the control scheme, see Remark 5. By defining the stacked vectors

\[
\begin{bmatrix}
\begin{bmatrix} u_0 \\ \vdots \\ u_{N-1} \end{bmatrix} \in \mathbb{R}^{N_n}, \begin{bmatrix} x_0 \\ \vdots \\ x_N \end{bmatrix} \in \mathbb{R}^n, \begin{bmatrix} \zeta_0 \\ \vdots \\ \zeta_N \end{bmatrix} \in \mathbb{R}^{N_c}
\end{bmatrix}
\]

where \( \zeta \) stands for \( f, \hat{f}, p, q, z, \bar{d} \) and \( N_n = N_n, N_u = N_n u, \) and \( N_c = (N + 1)t n_c, \) we get

\[
\begin{bmatrix}
\begin{bmatrix} A & B_u & B_p \\ C_q & D_{qu} & 0 \\ C_f & D_{fu} & 0
\end{bmatrix} & \begin{bmatrix} x_0 \\ u \end{bmatrix}, p = \Delta \hat{q}
\end{bmatrix}
\]  

(4)
with $\Delta \in \mathcal{D} \subset \mathbb{R}^{N_p \times N_q}$ where

$$\mathcal{D} = \{\text{diag}(\Delta_0, \Delta^0, \ldots, \Delta_{N-1}, \Delta^0_{N-1}, \Delta_N) : \Delta_k \in \mathbb{D}, \Delta^0_k \in \mathbb{D}^*\}$$

and where the stacked matrices in (4) (shown in bold) have the indicated dimensions and are readily obtained from iterating the dynamics in (3) and the redefinitions in this section. The input signal $u_i$ is considered as a causal state feedback that depends only on states $x_0, \ldots, x_i$ (see, e.g., [31]). Thus

$$u = K_0 x_0 + K x + v$$

(5)

where $v \in \mathbb{R}^{N_u}$ is the (stacked) control perturbation vector and $K_0, K$ are the current and predicted future state feedback gains. Causality is preserved by restricting $[K_0 \bar{K}] \in \mathcal{K} \subset \mathbb{R}^{N_u \times N_u}$, where $\mathcal{K}$ is the set of $N_u \times N_u$ lower block triangular matrices with $n_u \times n$ blocks, $K_0, K$, and $v$ are considered as decision variables. Note that, while $K_0$ is redundant for a given $x_0$ as it can be absorbed in $v$, we keep it for when we tackle the case of variable $x_0$ in Section V. Substituting the expression of $x$ in (4) into (5) gives

$$u = K_0 x_0 + K B_p p + \hat{v}$$

(6)

where $[K_0 \bar{K}] = (I - K B_p)^{-1} [K_0 + K A K] v$. Note that $(I - K B_p)$ is invertible due to the lower-triangular structure and that $u$ is affine in $K_0, \bar{K}$, and $\hat{v}$, which have the same form as $K_0, K$, and $v$. A standard feedback reparameterization gives

$$[K_0 \bar{K}] v = (I + K B_p)^{-1} [K_0 - K A K] \hat{v}$$

(7)

and so $[K_0 \bar{K}] \hat{v}$ will be used as the decision variables instead. Using (6) to eliminate $u$ from (4) and rearranging $x_0$ gives

$$\begin{bmatrix} q \\ z - \hat{z} \end{bmatrix} = \begin{bmatrix} \frac{D_k^{\bar{K}} D^{\bar{K}^0} - D_k^{K} D^{K^0}}{D_k^{K} D^{K^0} - D_k^{\bar{K}}} \\ \frac{D_k^{\bar{K}} D^{K} - D_k^{K} D^{\bar{K}^0}}{D_k^{K} D^{K^0} - D_k^{\bar{K}}} \end{bmatrix} \begin{bmatrix} p \\ 1 \end{bmatrix}$$

$$+ \begin{bmatrix} D_{kq} + D_{kq} K B_p D_{kqu} v + (C_q + D_{kq} K_0) x_0 + \hat{d} \\ D_{fp} + D_{fp} K B_p D_{fpq} u v + (C_f + D_{fp} K_0) x_0 - \hat{d} \end{bmatrix}$$

$$+ \begin{bmatrix} D_{kq} + D_{kq} K B_p D_{kq} u \hat{v} + (C_q + D_{kq} K_0) x_0 - \hat{d} \\ D_{fp} + D_{fp} K B_p D_{fp} \hat{v} + (C_f + D_{fp} K_0) x_0 - \hat{d} \end{bmatrix}$$

where $\mathcal{W}$ is defined to be the set of all feasible control variables $(\bar{K}_0, \bar{K}, \hat{v})$ such that all the problem constraints are satisfied $\mathcal{W} = \{(\bar{K}_0, \bar{K}, \hat{v}) \in \mathcal{K} \times \mathbb{R}^{N_u} : \mathcal{F}(\bar{K}_0, K, \hat{v}, \Delta) \leq \bar{f} \forall \Delta \in \mathcal{D}\}$.

$K_0, K$, and $v$ can be computed online and applied in the usual receding horizon MPC manner, where the first input of the control sequence $u$ is applied to the plant, the time window is shifted by 1, the current state is read and the process is repeated. Since the optimization in (10) is nonconvex, a semidefinite relaxation is used by introducing an upper bound $\gamma^2$ on the cost function. Using Lemma 1 and a Schur complement argument, the next result derives nonlinear conditions for solving (10).

Theorem 1: Let all the variables be defined as above. Then, $\mathcal{F}(\bar{K}_0, K, \hat{v}, \Delta) \leq \gamma^2$ and $\mathcal{F}(\bar{K}_0, K, \hat{v}, \Delta) \leq \bar{f}$ for all $\Delta \in \mathcal{D}$ if there exists a solution to the nonlinear matrix inequalities

$$T_1 + \mathcal{F}(T_2 K B_p T_3) > 0$$

(11)

$$T_1^2 + \mathcal{F}(T_2 K B_p T_3^2) > 0, \quad i = 1, \ldots, N_f$$

(12)

where

$$T_1 = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad T_2 = \begin{bmatrix} 0 \\ \gamma^2 \end{bmatrix}, \quad T_3 = \begin{bmatrix} 0 \\ -\Delta \end{bmatrix},$$

$$\begin{bmatrix} N_q \\ 0 \end{bmatrix} G^T_q \begin{bmatrix} S_1 \\ 0 \end{bmatrix} \leq \begin{bmatrix} N_q \\ 0 \end{bmatrix} G^{\bar{K}}_q \begin{bmatrix} S_1 \\ 0 \end{bmatrix} \leq \begin{bmatrix} N_q \\ 0 \end{bmatrix} G^T_q \begin{bmatrix} S_1 \\ 0 \end{bmatrix}$$

where $([K_0, K], \hat{v}) \in \mathcal{K} \times \mathbb{R}^{N_u}$ and $(S, R, G), (S_i, R_i, G_i) \in \mathcal{W}, i \in N_f := \{1, \ldots, N_f\}$ are slack variables with $\hat{W}$ defined in (1). In the sequel, we will occasionally write $T_i (\gamma^2, \bar{K}, \hat{v}, S, R, G)$, etc., to emphasize dependence on the variables. It follows that the relaxed RMPC problem can be summarized as

$$\min \{\gamma^2 : ([K_0, \bar{K}], \hat{v}) \in \mathcal{K} \times \mathbb{R}^{N_u}, (11), (12)\}$$

satisfies

$$\begin{bmatrix} S_i \\ R_i, G_i \end{bmatrix} \in \mathcal{W}, i \in N_f.$$

(13)

Definitions (8) and (9) verify that (13) is nonlinear due to terms of the form $K B_p \hat{W}$; where $\hat{W}$ stands for $S_i, R_i, G_i$ and $\hat{W}$; Note that (13) is linear for fixed $K$ and RMPC schemes with fixed $K$ have been proposed [32]. However, this introduces conservatism depending on the choice of $K$. A linearization scheme is proposed in [26], which uses an $S$-procedure to separate $\hat{K}$. However, this scheme has a high computational burden. Furthermore, some of the introduced linearization variables are restricted to a specific form. To overcome these two limitations, a new linearization procedure for (13) is proposed, which substantially reduces the computational complexity at the expense of only minor conservatism in the formulation.

III. LINEARIZATION SCHEME FOR THE RELAXED RMPC PROBLEM

The LMI-based methods reduce conservatism by explicitly incorporating uncertainty within the online optimization. However, they suffer from a heavy computational cost, which makes them impractical for systems with a high number of states or fast dynamics. In this section, a novel linearization procedure is proposed to overcome the nonconvexity for
the RMPC problem in (13), while conservativeness and computation burden are kept at low levels. We will use the following form of the Elimination Lemma.

**Lemma 2 (Elimination Lemma):** Let \( Q = Q^T \in \mathbb{R}^{n \times n}, B \in \mathbb{R}^{n \times m}, \) and \( C \in \mathbb{R}^{n \times p} \) be given matrices and let \( B^+ \) and \( C^+ \) denote orthogonal complements of \( B \) and \( C \), respectively. Then, the following two statements are equivalent: (i) \((B^+)^T Q (B^+) \succ 0 \) and \((C^+)^T Q (C^+) \succ 0 \); (ii) \( \exists Z \in \mathbb{R}^{n \times n}: \quad Q + \mathcal{H}(CZB^T) \succ 0 \).

The proof and some applications of the Elimination Lemma can be found in [33] and [34]. We use the Elimination Lemma to derive LMI sufficient conditions for the nonlinear matrix inequality conditions of Theorem 1.

**Theorem 2:** Let all variables be as defined Section II. Then, \( \mathcal{P}(K_0, K, \delta, \Delta) \leq \gamma^2 \) and \( \mathcal{F}(K_0, K, \delta, \Delta) \leq \mu \) for all \( \Delta \in \Delta \) if there exist solutions \( ([K_0^T, K]^T) \in K \times \mathbb{R}^{N_u}, \quad X \in \mathbb{R}^{n \times n}, \quad \) with lower block-diagonal with \( n \times n \) blocks, \((S, R, G), (S_i, R_i, G_i) \in \Psi, \quad \forall i \in \mathcal{M}\) to the following LMI:

\[
\begin{bmatrix}
T_1 + \mathcal{H}(T_2 K_0^+) & * \\
(B_p T_3 - \hat{K} T_2^T) & -X Y^T + X T^T
\end{bmatrix} \succ 0 \quad \text{(14)}
\]

\[
\begin{bmatrix}
T_1 + \mathcal{H}(T_2 K_0^+) & * \\
(B_p T_3 - \hat{K} T_2^T) & -X Y^T + X T^T
\end{bmatrix} \succ 0 \quad \text{(15)}
\]

for some \( Y^* \in \mathbb{R}^{n \times n}, \Delta \) and \( \mathcal{F}(K_0, K, \delta, \Delta) \leq \mu \) for all \( \Delta \in \Delta \) if there exist solutions \( ([K_0^T, K]^T) \in K \times \mathbb{R}^{N_u}, \quad X \in \mathbb{R}^{n \times n}, \quad \) with lower block-diagonal with \( n \times n \) blocks, \((S, R, G), (S_i, R_i, G_i) \in \Psi, \quad \forall i \in \mathcal{M}\) to the following LMI:

\[
\begin{bmatrix}
T_1 + \mathcal{H}(T_2 K_0^+) & * \\
(B_p T_3 - \hat{K} T_2^T) & -X Y^T + X T^T
\end{bmatrix} \succ 0 \quad \text{(16)}
\]

and let \( Y^* = \mathcal{P}(B_p T_3(S_i^*, G_i)) + (T_2 K_0^+)^T \) and \( Y_i^* = \mathcal{P}(B_p T_3(S_i^*, G_i)) + (T_2 K_0^+)^T \). Then, (14) and (15) are feasible.

**Proof:** We prove the first part by proving that the LMI in (14) and (15) are sufficient for the nonlinear matrix inequalities in (11) and (12), respectively. We first use the Elimination Lemma to give an equivalent form to (11). In order to separate \( K \) from \( T_3 \), the inequality in (11) can be rearranged as

\[
\begin{bmatrix}
I & T_2 K \\
B_p T_3 & 0
\end{bmatrix}
\begin{bmatrix}
T_1 & T_2^T B_p^T \\
B_p T_3 & 0
\end{bmatrix}
\begin{bmatrix}
I \\
\hat{K} T_2^T
\end{bmatrix} \succ 0.
\]

Then, applying the Elimination Lemma 2 on (17) with \( B = I \) shows that (17), hence (11) is equivalent to

\[
\begin{bmatrix}
T_1 & T_2^T B_p^T \\
B_p T_3 & 0
\end{bmatrix}
\begin{bmatrix}
T_1 & T_2^T B_p^T \\
B_p T_3 & 0
\end{bmatrix}
\begin{bmatrix}
I \\
\hat{K} T_2^T
\end{bmatrix} \succ 0.
\]

where \( Y \) and \( X \) are free slack variables. Since \( \mathcal{H}(X) \succ 0 \), \( X \) is nonsingular and we can define \( \hat{K} := K X \) as a new variable. To preserve the structure of \( \hat{K} \), which ensures causality, we restrict \( X \) to be block lower triangular (with \( n \times n \) blocks). To preserve linearity, we restrict \( Y \) to have the form \( Y = -X Y^* + Y^* \) (but not a variable). Substituting \( Y = -X Y^* \) into (18) proves that (14) is sufficient for (11) (but not necessary due to the restrictions on \( Y \) and \( X \)). A similar procedure proves that (15) are sufficient for (12). Next, we prove feasibility of (14) and (15). To show that (14) has a feasible solution, set \( (\gamma^2, K_0^*, \hat{K}, \hat{v}, R, S, G, I) = (\gamma^2, K_0^*, \hat{K}, \hat{v}, R, S, G, I) \). Then, the LHS of (14) becomes

\[
T^* := \begin{bmatrix}
T_1 + \mathcal{H}(T_2 K_0^*) & (B_p T_3 + (K^*)^T T_2^T) \\
(B_p T_3 + (K^*)^T T_2^T) & -2(K^*)^T T_2^T 2I
\end{bmatrix}
\]

where \( T^* := T_1 (\gamma^2, K_0^*, \hat{K}, \hat{v}, R, S, G, I) \) and \( T_3 := (S^*, G^*) \). Applying a Schur complement on \( T^* \) shows that \( T^* \succ 0 \) if and only if (16) is satisfied. It follows that (14) is feasible if (16) is. A similar procedure proves the feasibility of (15).

**Remark 1:** Theorem 2 provides sufficient LMI conditions for the initial nonconvex RMPC problem. Therefore, \( K_0, K, \) and \( v \) can be computed online and applied in a receding horizon manner as stated in Section II-C.

**Remark 2:** In comparison to [26], the novelty of the proposed linearization procedure is that it does not restrict the structure of the slack variables \((R, S, G)\) and \((R_i, S_i, G_i)\) beyond the requirements of \( \hat{K} \), and therefore it is less conservative.

### IV. SINGLE LMI APPROACH FOR HANDLING CONSTRAINTS SIGNAL FOR RMPC PROBLEM

Instead of solving multiple matrix inequalities for the constraints [one for each of the \( N_f \) constraints (12) or (15)], we propose a strategy to combine all within a single inequality. This results in reduced computational complexity and improved algorithm scalability. Our algorithm is based on the following result which uses an S-procedure to derive one LMI condition that is sufficient for a set of elementwise inequalities.

**Theorem 3:** Let \( f \in \mathbb{R}^{N_f} \) and let \( e \in \mathbb{R}^{N_f} \) be the vector of ones. Then, \( \hat{f} \geq 0 \) if there exist \( \mu \in \mathbb{R} \) and \( M \in \mathbb{D}^{N_f} \) such that

\[
\mathcal{L} := \begin{bmatrix}
2 \mu (f - M e - e \mu)^T & * \\
M & M^T
\end{bmatrix} \succeq 0.
\]

**Proof:** Let \( \Omega := \{ \text{diag}(\delta_1, \ldots, \delta_{N_f}) : \delta_i \in [0, 1], \sum_{i=1}^{N_f} \delta_i = 1 \} \). Then

\[
\hat{f} \geq 0 \Leftrightarrow e^T \hat{f} + \hat{f}^T \Delta \hat{f} \succeq 0 \quad \forall \Delta \in \Omega.
\]

Let \( \Delta \in \Omega \). Since \( \delta_i \in [0, 1] \) and \( \sum_{i=1}^{N_f} \delta_i = 1 \), then

\[
M \Delta := M + M^T \Delta - (M + M^T) \Delta = 0 \quad \forall M \in \mathbb{D}^{N_f}
\]

\[
\mu \Delta := e^T \Delta e \mu + \mu e^T \Delta e - 2 \mu = 0 \quad \forall \mu \in \mathbb{R}
\]

respectively. It is straightforward to verify the identity

\[
e^T \hat{f} + \hat{f}^T \Delta \hat{f} = e^T M \Delta e + e^T \Delta e + [1 e^T \Delta] \mathcal{L} \left[ \begin{array}{c}
\Delta \hat{f} \\
e^T \Delta e
\end{array} \right].
\]

The proof now follows from (20) and (21).

**Theorem 4:** Let all variables be as defined Section II. Then, \( \mathcal{P}(K_0, K, \delta, \Delta) \leq \gamma^2 \) and \( \mathcal{F}(K_0, K, \delta, \Delta) \leq \mu \) for all \( \Delta \in \Delta \) if there exist solutions \( ([K_0^T, K]^T) \in K \times \mathbb{R}^{N_u}, \quad (S, R, G), (S_i, R_i, G_i) \in \Psi, \quad \forall i \in \mathcal{M}, \) and \( M \in \mathbb{D}^{N_f} \) to (11) and

\[
\hat{T}_1 + \mathcal{H}(\hat{T}_2 K_0^*) \succeq 0
\]

(22)
where
\[
\begin{bmatrix}
\tilde{T}_1 \\
\tilde{T}_2 \\
\tilde{T}_3
\end{bmatrix} =
\begin{bmatrix}
1 & N_f & N_q & N_p \\
2(\mu - Df) & M + M^T & -Df & 0 \\
N_f & M + M^T & -Df & 0 \\
N_q & -Df & -Df & 0 \\
N_p & -Df & -Df & 0
\end{bmatrix}. 
\]

Proof: We only need to prove that (22) is sufficient for \( \hat{f} := \hat{f} - f \geq 0 \) for all \( \Delta \in \mathbb{R}^2 \), where \( \hat{f} \) is defined in (9). Using Theorem 3 and rearranging (19) verifies that a sufficient condition for the constraints is
\[
H_{11} + \mathcal{H}(H_{12}^1 \Delta (I - H_{22}^1 \Delta)^{-1} H_{22}^1) > 0 \quad \forall \Delta \in \mathbb{R}^2 
\]  
where we have used a strict inequality to avoid issues related to ill-conditioning near optimality and where
\[
H_{11}, H_{12}, H_{22}, H_{21} :=
\begin{bmatrix}
2\mu \left( \hat{f} - Df_{K_0} - M - \mu e \right) & \cdots & 0 \\
\cdots & \cdots & \cdots \\
0 & \cdots & 2\mu \left( \hat{f} - Df_{K_0} - M - \mu e \right)
\end{bmatrix}
\begin{bmatrix}
M & -Df & 0 \\
-Df & -Df & 0 \\
0 & -Df & -Df
\end{bmatrix}
\begin{bmatrix}
K_0 \\
K_0 \\
K_0
\end{bmatrix}. 
\]

Using Lemma 1 on (23) and the definition of (8) yields the matrix inequality (22) as a sufficient condition.

Using the linearization procedure in Section III, we next derive sufficient LMI conditions for the problem stated in (13).

Theorem 5: Let all variables be defined as Theorem 4. Then, \( \mathcal{H}(K_0, \hat{K}, \hat{L}, \hat{D}) \leq \gamma_2 \) and \( \mathcal{H}(K_0, \hat{K}, \hat{L}, \hat{D}) \leq \gamma_1 \) for all \( \Delta \in \mathbb{R}^2 \) if there exist \( (\hat{K}_0, \hat{K}), \hat{L} \in \mathbb{R}^{N_x, (S, R, G)} \), \( \hat{D} \in \mathbb{R}^{N_x, N_y} \), \( \mu \in \mathbb{R}, M \in \mathbb{R}^{N_x, N_x} \), and \( X \in \mathbb{R}^{N_x \times N_x} \), with \( X \) lower block-triangular with \( n \times n \) blocks, to (14) and the following LMI:
\[
\begin{bmatrix}
\hat{T}_1 + \mathcal{H}(\hat{T}_2 \hat{Y}) \\
B_p \hat{T}_2 - \hat{K}_p \hat{Y} - X \hat{Y}^* \\
S & \hat{S}
\end{bmatrix} > 0 
\]

for any \( \hat{Y}^* \in \mathbb{R}^{N_x \times (N_x + 1 + N_y + N_p)} \), \( \hat{Y}^* \in \mathbb{R}^{N_x \times (1 + N_f + N_y + N_p)} \), and where \( \hat{K} := \hat{K} \in \mathbb{R}^{N_x} \). Furthermore, that (11) and (22) have feasible solutions for \( (\gamma_2, \gamma_1, \hat{K}, \hat{L}, \hat{R}, s, g, \hat{R}, \hat{S}, \hat{G}) = (\gamma_2^*, \gamma_0^*, \hat{K}, \hat{L}, \hat{R}, s, g, \hat{R}, \hat{S}, \hat{G}) \) so that (16) and
\[
\tilde{T}_1 = (\hat{K}_0, \hat{K}, \hat{L}, \hat{R}, \hat{S}, \hat{G}) + \mathcal{H}(\tilde{T}_2 \tilde{K}) > 0 
\]

are satisfied and let \( \hat{Y}^* = B_p \hat{T}_3 \tilde{S}^* + (T_2 \hat{K}^*)^T \) and \( \hat{Y}^* = B_p \hat{T}_3 \tilde{S}^* + (\hat{T}_2 \hat{K}^*)^T \). Then, (14) and (24) are feasible.

Proof: The result can be proved by applying the Elimination Lemma 2 on (22) in a similar procedure to that used in the proof of Theorem 2 and is omitted.

Remark 3: Note that (19) gives only sufficient conditions for \( \hat{f} \geq 0 \) and can be conservative. To reduce the conservativeness, we can add redundant constraints, e.g., \( \sum_{i=1}^{N_y} \tilde{g}_i = 1 \). However, this is not pursued here. Our numerical experimentation, including the examples below, indicates that the single LMI sufficient condition provided by Theorem 5 performs as well as the multiple LMI conditions provided by Theorem 2.

V. FEASIBILITY ANALYSIS

A major problem in MPC is to ensure that the constraints are feasible. Infeasibility may arise if the constraints are too tight or it may be due to the approximations used to obtain a practical solution. In the context of this work, to guarantee feasibility, Theorems 2 and 5 require initial feasible solutions to (11), and (12) (to compute \( Y^* \) and \( Y^* \)) or (11) and (22) (to compute \( Y^* \) and \( Y^* \)). On the other hand, (11) and (12) are nonlinear and difficult to solve and these computations need to be carried out online. In this section, we develop algorithms that address these issues that involve extensive computations, which, however, are convex and can be carried out offline. We will concentrate on Theorem 5 since the procedure for Theorem 2 is similar.

Our approach is to find solutions to (11) and (22) offline that are feasible for every \( x_0 \) in a constrained set. Note that both (11) and (22) can be written as \( M(x_0) := M_1 + \mathcal{H}(M_2 x_0 M_3) > 0 \) in which \( M_1 \) is constant and \( M_1 \) and \( M_2 \) are independent of \( x_0 \), see (8). The next result uses an S-procedure to derive sufficient conditions for \( M(x_0) > 0 \) for all \( x_0 \) in a polytopic set and forms the basis for our Algorithm 1.

Theorem 6: Let \( M_1 = M_1^T \in \mathbb{R}^{m \times m}, M_2 \in \mathbb{R}^{m \times n}, M_3 \in \mathbb{R}^{1 \times m}, C_0 \in \mathbb{R}^{n \times n}, g_0 \leq g_0 \in \mathbb{R}^n \) be given. Then, \( M_1 + \mathcal{H}(M_2 x_0 M_3) > 0 \) for all \( x_0 \in \mathcal{X}_0 := \{ x_0 \in \mathbb{R}^n : g_0 \leq g_0 \leq g_0 \} \) if there exists \( 0 \leq D_0 \in D^0 \) such that
\[
L := \begin{bmatrix}
M_1 + \frac{1}{2} \mathcal{H}(M_2^T (g_0^T D_0 g_0) M_3^T) & \ast \\
\ast & \ast
\end{bmatrix} \succ 0
\]

Proof: A manipulation verifies the following identity:
\[
M_1 + \mathcal{H}(M_2 x_0 M_3) = M_0 + \left[ I_m \right]_m M_0^T \left[ x_0 M_3 \right]_m \]
where \( M_0 := M_1^T (g_0^T D_0 g_0) M_3 \) and \( g_0 \) is the result from the constraints on \( x_0 \) and the structure and sign-definiteness of \( D_0 \) (which ensure that \( M_0 > 0 \) for all \( x_0 \in \mathcal{X}_0 \)) and since \( L > 0 \) (which ensures that the second term on the RHS of the identity is positive definite for all \( x_0 \in \mathbb{R}^n \)).

Algorithm 6 gives an LMI procedure for solving (11) and (22) for all \( x_0 \in \mathcal{X}_0 \) when \( K \) is given and for solving (14) and (24) for all \( x_0 \in \mathcal{X}_0 \) when an initial feasible solution for (11) and (22) is given. Algorithm 1 outlines the suggested offline policy for computing initial feasible solutions for Theorem 5.

Remark 4: If \( \beta = 1 \) at the end of Step 2, we have feasible solutions to (11) and (22) for all \( x_0 \in \mathcal{X}_0 \) and we can use Theorem 5 online. If fewer online computations are needed, Theorem 4 can be used online with \( \hat{K} = \hat{K}^* \) and \( \hat{K}_0 \) can be used to minimize \( \gamma_1 \). If \( \beta > 1 \) at the end of Step 2, then, with minor modifications to Algorithm 1, Theorem 5 can still be used, although without a guaranteed feasible solution, but possibly a good initial solution if \( \beta \sim 1 \) since the conditions are not necessary. Alternatively, we may subdivide \( \mathcal{X}_0 \) into subsets, find a feasible solution for each and use a look-up table to choose the initial solution given \( x_0 \) in the online implementation. A systematic procedure for subdividing \( \mathcal{X}_0 \) is under investigation, however, see Example 1 for more details.

Remark 5: Although this work concentrates on solving effectively the RMPC control problem at the first iteration, some comments regarding recursive feasibility are given here. By selecting the terminal costs and constraints to lay inside a robust control invariant set, using a dual-mode controller similarly to [26], recursive feasibility and stability of the overall control scheme can be achieved. An alternative approach for recursive feasibility of the robust optimal control problem can be potentially proven by an adaptive horizon method similar to the work in [25]. However, further investigation into recursive feasibility and stability have been left for future work.
VI. NUMERICAL EXAMPLES AND SIMULATIONS

The effectiveness of our algorithms is illustrated by two examples. We use the CVX package [35] in MATLAB R2019b on a computer with 2.40 GHz Intel Xeon(R) CPU and 64.0 GB memory.

A. Example 1

The system is a variation on that proposed in [17], [18], and [26]. It is a second-order unstable process subject to uncertainty and bounded disturbances. The dynamics have the form of (3) with

\[
A = C_q = \begin{bmatrix} 1 & 0.8 \\ 0.5 & 1 \end{bmatrix}, \quad B_u = D_{qu} = \begin{bmatrix} 1 \\ 1 \end{bmatrix},
\]

\[
B_w = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix}, \quad B_p = 0.1I_2, \quad C_q = 0.
\]

The time-invariant uncertainty has the form \( \Delta := \{ \delta I_2 : \delta \in \mathbb{R} \} \) and the disturbances set is \( \mathcal{W} := \{ w \in \mathbb{R}^{n_w} : -1 \leq w \leq 1 \} \). The constraints are \(-\bar{u} \leq u_k \leq \bar{u}, k = 0, \ldots, N-1 \) and \(-\bar{x} \leq x_k \leq \bar{x} = [7.7^T, k = 0, \ldots, N, \text{respectively,} \) and the initial state is set at the state constraints boundary \( x_0 = \bar{x} \). The control objective is to regulate the unstable system subject to uncertainties and disturbances into the origin whilst satisfying the input and state constraints. The states and inputs are equally weighted in the cost function. Two RMPC algorithms are used. The first, CE-RMPC \#1 (\( \hat{K}_0, \hat{K}, \hat{\upsilon} \)), is described by Theorem 5, where the initial feasible solutions \( (Y^*, \tilde{Y}^*) \) are computed offline by Algorithm 1. The second algorithm, CE-RMPC \#2 (\( \hat{K}_0, \hat{\upsilon} \)), is described by Theorem 4, where \( \hat{K} = \hat{K}^* \) (computed offline by Algorithm 1).

For this example, \( \beta \) is greater than 1 if we take \( X_0 \) to be the entire constrained state-space \( (X_0 := \{ x_0 : -\bar{x} \leq x_0 \leq \bar{x} \} \)). Thus, \( X_0 \) is divided into 25 smaller sets \( X_{i,j}^* \), with \( \beta = 1 \) for each of these sets, and a look-up table has been used to store \( (Y^*, \tilde{Y}^*) \) for each subset. The subsets used are

\[
X_{i,j}^* = \{ x_{i,j} = \begin{bmatrix} x_{i,j,1} \\ x_{i,j,2} \end{bmatrix} : -\bar{x} \leq x_{i,j,1} \leq \bar{x}, -\bar{x} \leq x_{i,j,2} \leq \bar{x} \}, \quad i, j = 1, \ldots, 5
\]

where for \( k = 1, 2 \)

\[
[\bar{x}_{i,j,1}^k, \bar{x}_{i,j,1}^k] = [7.75, 1], \quad [\bar{x}_{i,j,2}^k, \bar{x}_{i,j,2}^k] = [7.4, 7.75], \quad [\bar{x}_{i,j,3}^k, \bar{x}_{i,j,3}^k] = [7.4, 7.4]
\]

\[
[\bar{x}_{i,j,4}^k, \bar{x}_{i,j,4}^k] = [-7.75, 1], \quad [\bar{x}_{i,j,5}^k, \bar{x}_{i,j,5}^k] = [-7.4, 7.4]
\]

The time to compute the initial solutions \( (Y^*, \tilde{Y}^*) \) for all subsets is 94.5 s. Note that offline computation time depends on the number of subsets and terminal iteration values \( i_{max} \) and \( j_{max} \). The controller from [26] is also presented for comparison. All algorithms are simulated with prediction horizon \( N = 5 \).
by our algorithms, where it can be seen that the input reaches the constraint boundaries, in contrast with the algorithm in [26]. Therefore, our algorithms are less conservative, even for fixed $K$, due to the novel linearization procedure (see Remark 2). The most notable outcome using our algorithms is that they required significantly lower computation burden compared to the methods from the literature. In particular, as shown in Table I, using the CE_RMPC#1 ($\bar{K}_0, \bar{K}, \bar{v}$) procedure results in the average and maximum computation cost per iteration being reduced by 94% and 92%, respectively, as compared to the algorithm proposed in [26]. Implementing CE_RMPC#2 ($\bar{K}_0, \bar{v}$) results in the average and maximum computation cost per iteration being reduced by 96% and 94%, respectively, in comparison to the time required by the algorithm in [26]. The numerical values in Table I were realized using the same computer to solve the abovementioned regulation problem and repeated 10 times for each method.

**B. Example 2**

The benchmark problem of control tracking of a coupled two-mass-spring system is considered [15], [26]. Discretizing the system using Euler’s first-order approximation for the derivative with sample time 0.1 s gives a fourth-order linear discrete-time state space model $x(k + 1) = Ax(k) + Bu(k)$. Here, $A$ depends on the masses $m_1, m_2$ and the spring constant $K$. The states $x_1, x_2$ are the mass displacements whereas $x_3, x_4$ are the respective velocities. The nominal values are $m_1 = m_2 = K = 1$ in normalized units and the control force $u$ acts on $m_1$.

The objective is for the output $(x_2)$ to track a unit step while satisfying the constraints $-1 \leq u(k) \leq 1$, $-\bar{x} \leq x(k) \leq \bar{x} := [1.5 \ 1.5 \ 1.1]^T$. In this setup, the state is measurable, while $K$ is uncertain within the range $0.5 \leq K_{\text{min}} \leq K \leq K_{\text{max}} = 10$, in appropriate units. The cost function weights are $C_u = [5 \ 0 \ 0 \ 0]^T$, $D_{\text{cu}} = [0 \ 0 \ 0 \ 0]^T$ and the prediction horizon is set as $N = 6$.

The output response in Fig. 2 shows that both proposed algorithms robustly steer the system to the reference signal. Fig. 2 also shows the responses of the infinite horizon methods in [15] and [16] and the finite horizon method in [26], as well as NL-RMPC$(\bar{K}_0, \bar{K}, \bar{v})$, which is described by Theorem 2 (new linearization RMPC with multiple LMI). It can be seen that our approaches converge much faster than the two infinite horizon methods. Comparing with [26], it can be seen that even though all algorithms have excellent tracking properties, the proposed controllers have slightly faster responses due to the less restrictive nature in the formulation (see Remark 2). Fig. 2 also shows that the control input calculated by the proposed algorithms is much faster and is closer to the upper bound. Our method also gives a much smaller cost function compared with the infinite horizon methods and similar cost compared with the finite horizon method in [26].

To quantify the effect of Theorem 5 compared with Theorem 2 with respect to feasibility domain, $K_{\text{max}}$ was increased until infeasibility is observed. CE_RMPC#1 and CE_RMPC#2 can obtain a solution for values up to $K_{\text{max}} = 20.5$, while NL-RMPC for values up to $K_{\text{max}} = 21$. Therefore, we can conclude that the large computation time reduction using the suggested algorithms (CE_RMPC#1 and CE_RMPC#2) comes with only a small reduction in the feasibility domain.

Comparing the computational times in Table II, it can be seen that CE_RMPC#1 has a similar computational burden as [15], [16], and is much faster than [26] and the algorithm NL-RMPC. A significant computation time reduction can also be observed for CE_RMPC#2. Therefore our approach combines the fast online computational performance of the infinite horizon methods and the good performance of the finite horizon approaches. Note that in general, a larger prediction horizon increases the computation time, while stability is improved. Restricting the computational time to be similar to infinite horizon methods from the literature (on average 1 sec), the prediction horizon was set to $N = 6$ to allow a fair comparison with respect to performance. Horizon length $N = 7$ gives an average computational time $t = 2.1845$ s, however, the control performance was not noticeably improved.

**VII. CONCLUSION**

In this work, two algorithms are proposed to reduce the computational complexity of state-feedback RMPC for linear-time-invariant discrete-time systems, subject to structured uncertainty and bounded disturbances.

The effectiveness of the proposed techniques is demonstrated through numerical examples taken from the literature. In particular, it has been shown that the proposed RMPC scheme can successfully calculate an optimal control signal up to 96% faster than other finite horizon RMPC, while being able to steer the system quicker to a predefined reference with minimum conservativeness compared with other RMPC approaches.

Although our proposed RMPC approach is LMI-based, nevertheless, a detailed comparison with tube-based RMPC methods is currently under active research.

**TABLE I**

| Method               | Mean ± Std Deviation | Maximum time |
|----------------------|----------------------|--------------|
| Talari et al. (2013) | $2.3457 ± 2.2337$ s  | 29.5438 s    |
| CE_RMPC #1 ($\bar{K}_0, \bar{K}, \bar{v}$) | $1.4187 ± 0.4482$ s  | 2.5313 s    |
| CE_RMPC #2 ($\bar{K}_0, \bar{v}$)          | $0.9187 ± 0.2686$ s  | 1.7656 s    |

**TABLE II**

| Method                                     | Mean ± Std Deviation | Maximum time |
|--------------------------------------------|----------------------|--------------|
| Inf. horizon RMPC from [15]                | $1.0748 ± 0.3321$ s  | 2.2813 s    |
| Inf. horizon RMPC from [16]                | $1.0679 ± 0.3002$ s  | 2.5625 s    |
| RMPC from [26]                             | $3.0672 ± 0.5137$ s  | 5.3750 s    |
| CE_RMPC #1                                 | $1.0734 ± 0.2695$ s  | 2.0156 s    |
| CE_RMPC #2                                 | $0.3502 ± 0.1044$ s  | 0.7117 s    |
| NL-RMPC                                    | $2.3547 ± 0.9762$ s  | 3.7656 s    |

Fig. 2. Output and control input signals for the proposed RMPC controllers compared with algorithms from the literature for Example 2.
