Influence of different elicitors on BIA production in *Macleaya cordata*

Peng Huang¹²⁷, Liqiong Xia³⁷, Li Zhou¹⁷, Wei Liu¹⁴, Peng Wang¹, Zhixing Qing⁵⁶ & Jianguo Zeng¹⁶

Sanguinarine (SAN) and chelerythrine (CHE) have been widely used as substitutes for antibiotics for decades. For a long time, SAN and CHE have been extracted from mainly *Macleaya cordata*, a plant species that is a traditional herb in China and belongs to the Papaveraceae family. However, with the sharp increase in demand for SAN and CHE, it is necessary to develop a new method to enhance the supply of raw materials. Here, we used methyl jasmonate (MJ), salicylic acid (SA) and wounding alone and in combination to stimulate aseptic seedlings of *M. cordata* at 0 h, 24 h, 72 h and 120 h and then compared the differences in metabolic profiles and gene expression. Ultimately, we found that the effect of using MJ alone was the best treatment, with the contents of SAN and CHE increasing by 10- and 14-fold, respectively. However, the increased SAN and CHE contents in response to combined wounding and MJ were less than those for induced by the treatment with MJ alone. Additionally, after MJ treatment, SAN and CHE biosynthetic pathway genes, such as those encoding the protopine 6-hydroxylase and dihydrobenzophenanthridine oxidase enzymes, were highly expressed, which is consistent with the accumulation of SAN and CHE. At the same time, we have also studied the changes in the content of synthetic intermediates of SAN and CHE after elicitor induction. This study is the first systematic research report about using elicitors to increase the SAN and CHE in *Macleaya cordata*.

The benzophenanthridine alkaloids (BIAs) are a large and diverse alkaloid group, and these compounds, such as sanguinarine (SAN), chelerythrine (CHE), protopine (PRO), and allocryptopine (ALL), exhibit a wide range of biological activities. SAN has a wide spectrum of biological activities, including strong antitumour, antimicrobial and anti-inflammatory activities. In addition, SAN and CHE are as natural growth promoters that can be used as alternatives to antibiotic growth promoters in the livestock industry. In addition, SAN has real potential as an effective antischistosomal drug. Both PRO and ALL were demonstrated to have anti-bacterial, anti-viral, anti-fungal and anti-parasitic effects. PRO has potential uses as a neuroprotective agent in stroke and as an antidepressant for mood disorders. Currently, SAN and CHE are extracted from mainly *Macleaya cordata*, a plant species that is a traditional herb in China and belongs to the Papaveraceae family. In 2006, with the ban of using low-dose antibiotics as growth promoters added in animal feed in the European Union, natural growth promoters (NGPs), such as phytogenics, are extensively exploited as alternatives to antibiotics in livestock production. Currently, the annual requirement for this plant is increasing daily due to its commercial value. Unfortunately, this plant has generally been collected from the wild for SAN commercial production. Therefore, the massive collection of wild resources of *M. cordata* caused a decline in its population and we need to establish a new stable supply method and develop a viable alternative to SAN production.

Plant tissue culture has become a promising alternative strategy for the sustainable and industrial-scale production of secondary metabolites. There are multiple advantages of medicinal plant tissue culture. (i) It is not

¹Hunan Key Laboratory of Traditional Chinese Veterinary Medicine, Hunan Agricultural University, Changsha 410128, Hunan, China. ²Animal Nutritional Genome and Germplasm Innovation Research Center, College of Animal Science and Technology, Hunan Agricultural University, Changsha 410125, Hunan, China. ³Clinical Pharmacy, Yueyang Hospital of TCM, Yueyang 414000, Hunan, China. ⁴College of Veterinary Medicine, Hunan Agricultural University, Changsha 410128, Hunan, China. ⁵College of Food Science and Technology, Hunan Agricultural University, Changsha, China. ⁶National and Local Union Engineering Research Center of Veterinary Herbal Medicine Resource and Initiative, Hunan Agricultural University, Changsha 410128, Hunan, China. ⁷These authors contributed equally: Peng Huang, Liqiong Xia, and Li Zhou. ⁸email: qingzhixing@hunau.edu.cn; zengjianguo@hunau.edu.cn
affected by environmental or geographic conditions. (ii) It can strictly control production and quality and (iii) shorten the growth cycle compared to that of the intact plant. (iv) It avoids taking land resources. In fact, some plant secondary metabolites have been produced using this method, such as shikonin14,15, ginseng saponins16 and paclitaxel17–19, over the past decades. Based on this strategy, some elicitors have been widely used to enhance secondary metabolite production in many plant species. For example, methyl jasmonate (MJ) treatments were found to enhance the production of camptothecin in Ophiopogon mungos20 and the content of ola A, withanolide A, withanone, and withaferin A in Withania somnifera.21 In addition, salicylic acid (SA) can increase the accumulation of secondary metabolites in Salvia miltiorrhiza cells22 and Daucus carota.23 Moreover, wounding responses have always occurred. For example, wind, hail, sand and cuts can increase the secondary metabolite production of plants.24,25 In fact, some researchers have to enhance SAN in Argemone Mexicana by MJ, Fusarium oxysporum homogenates.26 Additionally, the sequential application of MJ, SA and YE also can increase the SAN content over 9 times in A. Mexicana.27 Although the continuous treatment of MJ, SA and YE also can increase SAN 5.5 times in A. Mexicana28. However, another research found that the effect of MJ treatment was better.29 In addition, manganese chloride is also used to try to increase BIA in E. californica.30 However, there still is no report available regarding the elicitor or mechanical damage effect on BIA production in the tissue culture of M. cordata.

In 2017, the whole genome of M. cordata was sequenced, which is the first species in Papaveraceae to have a completed genome-wide sequence. Research on elicitors of M. cordata will further promote the study of the regulation of SAN synthesis. Currently, the protocol of regeneration and transformation in M. cordata has been established, and the SAN biosynthetic pathway and genes in M. cordata have been validated. The aim of this study was to evaluate the effects of MJ, SA and wounding on BIA metabolism in plant tissue culture seedlings to enhance SAN production in M. cordata. Moreover, multiple processing at different times was evaluated. Additionally, the effect of different elicitors was evaluated on the basis of the metabolic profile and gene expression in the SAN and CHE biosynthesis pathway.

Materials and methods

Plant materials and treatments. Sixty-day-old lines of M. cordata were maintained in hormone-free solid medium. All the cultures were under a 16/8 h (light/dark) cycle (4500 to 9000 lx) until used for transformation, and these tissues were used for all experiments. MJ (≥ 98%) and SA (≥ 99%) were purchased from Sigma (USA). They were filter sterilized using 0.22 μM membrane filters (Millipore, USA) and diluted in DMSO in triplicate each time. For wounding treatment, 60-day-old M. cordata Sigma (USA). They were filter sterilized using 0.22 μM membrane filters (Millipore, USA) and diluted in DMSO in triplicate each time. Samples were collected stored at −70 °C for future experiments. All the samples were collected at 0 h, 24 h, 72 h and 120 h to test the optimum incubation time required for the treatment to evoke the maximum response. Samples were collected in triplicate each time.

Metabolite extraction from M. cordata and LC/triple-quadrupole (QQQ) MS analysis. The methods of alkaloid extraction and metabolic analysis were performed using previously described methods.
The production of protopine and sanguinarine need to be catalysed by the enzymes encoded by the P6H and DBOX genes; therefore, the effect of the induction mode on the content can be further analysed by detecting the expression levels of these two genes. By analysing the mRNA expression levels of the P6H and DBOX genes (Fig. 3), which catalyse production of protopine and sanguinarine, the effect of the elicitor can be further analysed. We found that the P6H gene expression was the highest in the SA group at 24 h, which then decreased with time. In contrast to that in the SA group, the expression level of the DBOX gene was highest in the SA + wounding group at 72 h. Interestingly, the expression pattern of the DBOX gene was the opposite of that of P6H. All the treatments increased the expression of the DBOX gene, which increased with time, except for that in the SA + wounding group at 120 h. The highest expression was induced by MJ treatment in all methods, followed by that induced by SA treatment.

Table 1. Nucleotide sequences of primers.

| Primer Name | Oligonucleotide Sequences (5′–3′) |
|-------------|----------------------------------|
| McP6H-QP-F  | CATCAAGGACGTCCAGCCCT             |
| McP6H-QP-R  | CTCCTCACCCGACACAACT              |
| McDBOX-QP-F | ACTGTTGCCACGGTCGATAG             |
| McDBOX-QP-R | TGGAGGAGCTGTCAACAGCC             |
| 18S-QP-F    | CTTCCGGATCGGAGTAATGA             |
| 18S-QP-R    | GCGGAGTCCTAGAAGCAACA             |

Statistical analysis. All the experiments were performed in triplicates. Data were recorded at four different time points (0 h, 24 h, 72 h and 120 h). We used a one-way ANOVA with GraphPad Prism software (Version 8.4.0), followed by the Tukey’s honestly significant difference (HSD) post hoc test for mean comparison.

Results

Effect of different elicitors on SAN and CHE, ALL, PRO, dihydrosanguinarine (DHSAN) and dihydrochelerythrine (DHCHE) production. In M. cordata, PRO and ALL were transformed into 6-hydroxyprotopine by P6H and into the spontaneous intramolecular rearrangement forms DHSAN and DHCHE34,35, and these molecules were finally were oxidized to SAN and CHE by DBOX36,37. The contents of SAN and CHE were significantly higher after the MJ treatment than after the other treatments (P < 0.05) at 120 h (Fig. 2E,F). Compared with those in the untreated group, the contents of SAN and CHE were increased by 10- and 14-fold, respectively (Fig. 2E,F). In addition, treatment with SA and wounding resulted in less SAN and CHE accumulation compared with that in the MJ group (Fig. 2E,F). However, combined MJ and wounding enhanced SAN and CHE, PRO, and ALL production (Fig. 2A,B,E,F). Additionally, we compared the changes in alkaloid content after treatment for 120 h. The results showed that the impact of MJ increased with time. The SAN and CHE production showed a maximum of 2.54 ± 0.42 mg/g at 120 h after initiation of MJ treatment, and the combined MJ and wounding treatment produced a maximum of 1.6 ± 0.25 mg/g at 72 h after treatment, which was lower than after the treatment with MJ alone. Finally, we found that 3 treatments (MJ, SA, and wounding) had significant effects on the PRO and ALL contents (Fig. 2). In contrast, the PRO and ALL contents continuously declined over time and were lower than those in the untreated group at 120 h. In addition, treatment with MJ significantly increased (P < 0.05) the DHCHE content at 72 h. However, the wounding treatment in combination with either of the two other treatments (MJ or SA) had greater effects than the control, MJ and SA groups on the DHSAN content (Fig. 2).

Effect of different elicitors on P6H, DBOX genes expression levels. The production of protopine and sanguinarine need to be catalysed by the enzymes encoded by the P6H and DBOX genes; therefore, the effect of the induction mode on the content can be further analysed by detecting the expression levels of these two genes. By analysing the mRNA expression levels of the P6H and DBOX genes (Fig. 3), which catalyse production of protopine and sanguinarine, the effect of the elicitor can be further analysed. We found that the P6H gene expression was the highest in the SA group at 24 h, which then decreased with time. In contrast to that in the SA group, the expression level of the P6H gene was highest in the SA + wounding group at 72 h. Interestingly, the expression pattern of the DBOX gene was the opposite of that of P6H. All the treatments increased the expression of the DBOX gene, which increased with time, except for that in the SA + wounding group at 120 h. The highest expression was induced by MJ treatment in all methods, followed by that induced by SA treatment.
Discussion

Elicitation is one of the most effective methods to enhance the accumulation of secondary metabolites in plants. Some biotic elicitors or physical stimulations are always used to improve the production of secondary metabolites in vitro. MJ and SA have been proven to be signalling molecules involved in the plant defence response and are now widely used as elicitors for secondary metabolite production in vitro. Additionally, the concentration, type and time course of elicitors have a great impact on the accumulation of secondary metabolites. In previous studies, the treatment of plant cultures with MJ has been shown to increase the accumulation of...
Figure 3. The time course analysis of gene expression in different treatment groups. (A) Protopine 6-hydroxylase (P6H). (B) Dihydrobenzophenanthridine oxidase (DBOX). Asterisks denote the significant changes (Tukey’s test, * means $P<0.05$, ** means $P<0.01$, *** means $P<0.005$, **** means $P<0.001$) compared with 0 h group.

Triterpenoid saponins, alkaloids, and ginsenoside. Similarly, many studies have found that secondary metabolite products in SA-treated plant cells are also significantly increased. In addition, studies have found that mechanical damage increases and induces the production of various secondary metabolites, including volatiles. Wounding treatment also increased the accumulation of volatiles, including monoterpenes and sesquiterpenes. In Macleaya cordata, there have been some inconsistencies regarding the content of SAN after treatment with SA and MJ. However, in California poppy, both MJ and SA significantly increased the content of SAN. 

Based on the gene expression data, elicitor has a different effect on the P6H and DBOX genes. Specifically, MJ has a greater effect on the DBOX gene than on P6H. In contrast, SA has a greater effect on the P6H gene than on DBOX. In Argemone mexicana, yeast extract increases DBOX activity, but does not increase after MeJa induction. This shows that different species are affected differently by the elicitor. Based on these results, we believe that MJ is the best elicitor for increased SAN production, with hope for its application to the production of sanguinarine during harvesting in the future.
