(Dated: September 15, 2022)

Very recently, the CMS Collaboration reported the evidence of a four-$c\bar{c}$ fully charm tetraquark from $pp$ collision, by which the $X(6900)$ structure announced by the LHCb Collaboration was confirmed, but also more enhancement structures were discovered. Facing such a novel phenomenon, in this work we indicate that these new features reflected from the CMS measurement provide a good implication for a dynamical mechanism which reproduces the novel peaking phenomenon in the reported $J/\psi$-pair mass spectrum well. This mechanism is due to special reactions, where different charmonium pairs directly produced by $pp$ collision may transit into the final state of $J/\psi J/\psi$. The present work provides a special viewpoint to decode these observed fully charm structures in the $J/\psi$-pair invariant mass spectrum.

I. INTRODUCTION

The discovery of a series of new hadron states has stimulated theorists’ extensive interest in the study of exotic hadron configuration with more constituent quarks and gluons since 2003. With continuous efforts from experimentalists and theorists, more and more manifestly exotic structures have been identified, which include hidden-charm pentaquark $P_c(4312)\,^+,\,\,P_c(4440)\,^+,\,\,P_c(4457)\,^+$\textsuperscript{1}, a series of charmoniumlike $XYZ$ states as hidden-charm tetraquark candidates\textsuperscript{2,5}, doubly charmed tetraquark $T_{cc}^+$\textsuperscript{6}, and so on (see review articles\textsuperscript{[45–50]}, the gluonic tetracharm hybrid\textsuperscript{51}, a Higgs-like boson\textsuperscript{52}, etc. Additionally, the production property and decay behavior of fully charm tetraquark states were also discussed by several research groups\textsuperscript{[53–59]}. We should pay more experimental and theoretical efforts to clarify the nature of peaking phenomenon in the di-$J/\psi$ mass distribution.

Very recently, the CMS Collaboration released their measurements on the $J/\psi$-pair mass spectrum by using 135 fb\textsuperscript{−1} proton-proton data at center of mass energies of 13 TeV\textsuperscript{60}, which not only confirmed the existence of the $X(6900)$ reported by LHCb with significance 9.4\textsigma, but also found signals of some new peaking structures. By using a relativistic S-wave Breit-Wigner function, the resonance parameters of two new structures, the $X(6600)$ and $X(7300)$, were obtained\textsuperscript{60}:

\begin{align*}
m_{X(6600)} &= 6552 \pm 10 \pm 12 \text{ MeV}, \\
\Gamma_{X(6600)} &= 124 \pm 19 \pm 34 \text{ MeV}, \\
m_{X(7300)} &= 7287 \pm 19 \pm 5 \text{ MeV}, \\
\Gamma_{X(7300)} &= 95 \pm 46 \pm 20 \text{ MeV}.
\end{align*}

Undoubtedly, the new CMS measurement can provide more refined hints to decode the novel peaking phenomena appearing in the double $J/\psi$ mass spectrum.

Inspired by the new experimental results from CMS, in this work, we further apply a dynamical mechanism to understand these observed fully charm enhancement structures. Here, the adopted dynamical mechanism is based on a special reaction that different charmonium pairs from direct hadroproduction may transit into final states of di-$J/\psi$\textsuperscript{45}. This dynamical mechanism has succeed in explaining the $X(6900)$ as a threshold cusp structure resulting from the intermediate $\chi_{c0}\chi_{c1}$ scattering\textsuperscript{45}. As suggested in Ref.\textsuperscript{61}, we first extend this dynamical mechanism by considering higher-order multiloop contributions. By applying the extended dynamical
model to fit the line shape of the di-$J/\psi$ mass distribution measured by both CMS and LHCb, we demonstrate that in addition to the intermediate $J/\psi\psi(3686)$ and $\chi_{c0}\chi_{c1}$ scattering which are enough to explain the LHCb data, the contributions of the remaining two allowed characteristic intermediate channels $\chi_{c1}\eta_c$ and $\chi_{c2}\chi_{c2}$ in the measured energy region can be explicitly revealed by the features appearing in the CMS measurement, which can correspond to the newly observed fully charm enhancement structure around 6.6 and 7.3 GeV, respectively. Thus, this is direct evidence to support this dynamical production mechanism based on a double charmonia scattering. Furthermore, we discuss the origins of these di-$J/\psi$ peaking structures in the dynamical mechanism under two fitting schemes. The present study is helpful to improve the understanding of the peaking phenomena in the di-$J/\psi$ invariant mass spectrum.

This paper is organized as follows. After the Introduction, in Sec. II we present the theoretical framework of the extended dynamical mechanism of producing the fully charm enhancement structures in the di-$J/\psi$ mass spectrum. In Sec. III we discuss the improved understanding for the peaking phenomena in the double $J/\psi$ mass spectrum based on the CMS measurement. Finally, this paper ends with the discussion and conclusion in Sec. IV.

II. THE EXTENDED DYNAMICAL MECHANISM

The hadroproduction of double charmonium in a high-energy proton-proton collider is usually achieved by the $gg \rightarrow (c\bar{c})(c\bar{c}) + X$ process in single parton scattering (SPS) [62, 63] and the $gggg \rightarrow (gg \rightarrow c\bar{c}) (gg \rightarrow c\bar{c}) + X$ in double parton scattering (DPS) [70, 72]. This production mechanism usually plays a main role for producing the continuum distribution in the invariant mass spectrum of double charmonium, whereas the observed novel enhancement phenomenon in the di-$J/\psi$ mass spectrum by recent LHCb and CMS measurement tells us that a new origin of double $J/\psi$ hadroproduction should exist, which has stimulated some theoretical discussions on a dynamical production mechanism of the $J/\psi$ pair [45, 50, 74].

This new dynamical mechanism is based on a special reaction, where various combinations of double charmonia that are directly produced via both the SPS and DPS processes are transferred into final states of $J/\psi, J/\psi$. The combination selection of an intermediate charmonium pair depends on the quantum number conservation of the reaction system. This dynamical mechanism was proposed in our previous work for the first time and has been found to produce the X(6900) structure well [45]. In this work, we further extend this reaction picture to the multiloop case, where the higher-order coupling contribution of an intermediate double charmonia scattering to the same intermediate double charmonia will be taken into account. These contributions have been demonstrated to provide more abundant dynamical information for the intermediate scattering process [61]. The corresponding schematic diagrams are presented in Fig. 1 where the interaction between an intermediate charmonium pair and a transferred double charmonia is absorbed into a vertex. Here, it is worth mentioning that we have to ignore the coupled channel effects in the subsequent analysis because of the absence of relevant experimental data.

Concrete theoretical calculations on the direct production of double charmonium in high-energy proton-proton collisions by the SPS and DPS mechanisms are quite challenging [62, 77, 79]. Fortunately, here we focus only on the line shape of their contribution in the di-$J/\psi$ invariant mass spectrum. So the $S$-wave direct production amplitude of a double charmonium $H_{i\bar{i}}H_{\bar{j}j}$ marked in Fig. 1 can be parametrized as [15]

$$A_{\text{direct}}^{ij} = \left[ (g_{\text{direct}}^{ij})^2 \epsilon_{\text{com}ij} \right]^{1/2} \frac{1}{8\pi} \sqrt{\lambda} \left( m_i^2, m_j^2, m_{ij}^2 \right)$$

where $m_{ij}$ is the invariant mass of double charmonia $H_{i\bar{i}}H_{\bar{j}j}$. The Källen function is defined to be $\lambda(x, y, z) = x^2 + y^2 + z^2 - 2xy - 2x y - 2yz$. For the one-loop process with an $S$-wave interaction between intermediate charmonium pairs shown in Fig. 1 the scattering amplitude of producing a $J/\psi J/\psi$ becomes the one proportional to the scalar two-point loop integral, whose analytical form within a nonrelativistic form can be given by, in the rest frame of di-$J/\psi$,

$$L_{ij}(m_{J/\psi J/\psi}) = \int \frac{d^4q}{(2\pi)^4} \frac{i2\sqrt{2}e^{-\frac{1}{4}q^2 / \alpha^2}}{i(2\pi)^4} \left[ -\frac{2(2\mu\alpha)}{(2\mu\alpha)^{3/2}} \mathrm{erfi} \left( \sqrt{\frac{4\mu\alpha}{m_{J/\psi J/\psi}}} \right) - i \right] \right\},$$

where $\mu = (m_im_j)/(m_i + m_j)$, $m_0 = m_{J/\psi J/\psi} - m_i - m_j$, and $m_i (m_j)$ is the hadron mass of an intermediate charmonium $H_{i\bar{i}}^1 (H_{\bar{j}j}^1)$. Here, an exponential form factor $e^{-\frac{1}{4}q^2 / \alpha^2}$ with a cutoff parameter $\alpha$ is introduced to avoid the ultraviolet divergence of scalar two-point loop integral. In our previous work [45], the intermediate

![FIG. 1. The schematic diagrams for the dynamical production mechanism of a double $J/\psi$, where $H_{i\bar{i}}$ stands for allowed intermediate charmonium states. Here, the gray rectangle represents the direct production of a double charmonium in hadron colliders.](image-url)
charmion pairs $H_{c}^{+}H_{c}^{-} = J/\psi J/\psi$, $\eta_c \chi_{cJ}$, $J/\psi \eta_c$, and $\chi_{cJ} \chi_{cJ}$ with $J = 0, 1, 2$ were considered, which are the charmion combination composed of radially ground states and completely cover the concerned energy region from $6.194$ to $7.300$ GeV. Here, important evidence supporting these combinations is that the direct hadroproduction rates of these radially ground charmions have been proved to be comparable with that of $J/\psi$ by both experiments [80–84] and theoretical estimations from nonrelativistic QCD [82–86]. Of course, if one further extends the selection criterion to radically exciting charmion states, there should be two more channels $J/\psi \psi(3686)$ and $J/\psi \psi(3770)$ in the same energy region, whose possible contributions will be also investigated in this work. It is worth noticing that we include the width effects of intermediate charmion states by replacing $m_i$ in Eq. (2) with $(m_i - i \Gamma_i) / 2$.

When considering all combinations of a charmion pair, one can find that there exist 13 intermediate channels in the di-$J/\psi$ energy region from $6.194$ to $7.300$ GeV. Obviously, it is impossible to include so many dynamical reactions in a practical theoretical analysis. Fortunately, we found that their threshold positions are mainly concentrated in five local energy regions, which provides us convenience to deal with this problem. Considering the fact that the contributions of intermediate channels in the same local energy region may overlap and then behave like one peak structure, we can choose a representative channel to absorb the contributions from other nearby scattering channels. Thus, all possible dynamical scattering channels for double $J/\psi$ hadroproduction in the energy range below $7.3$ GeV include $J/\psi J/\psi$, $\eta_c \chi_{c1}$, $J/\psi \psi(3686)$, $\chi_{c0} \chi_{c1}$, and $\chi_{c2} \chi_{c2}$.

The two-loop and three-loop production amplitudes in Fig. 1 are proportional to $C_{ij} L_{ij}(m_{J/\psi J/\psi})^2$ and $-C_{ij} L_{ij}(m_{J/\psi J/\psi})^3$, respectively, and higher-order loop contributions can be written accordingly, where $C_{ij}$ represents the coupling strength of intermediate charmion pairs scattering to the same double charmonia. If we sum all loop diagram contributions, the line shapes of the invariant mass distribution of di-$J/\psi$ caused by the extended dynamical mechanism are given by

\[ A^{2}_{ij}(m_{J/\psi J/\psi}) = \frac{g^{2}_{ij} L_{ij}(m_{J/\psi J/\psi})^2}{(1+C_{ij} L_{ij}(m_{J/\psi J/\psi})^2)^2} \frac{e^{-i\phi_{mn}} m_{J/\psi J/\psi}}{m_{J/\psi J/\psi}} \tag{3} \]

and

\[ A^{3}_{ij}(m_{J/\psi J/\psi}) = \frac{g^{2}_{ij} L_{ij}(m_{J/\psi J/\psi})^2}{(1+C_{ij} L_{ij}(m_{J/\psi J/\psi})^2)^3} \frac{e^{-i\phi_{mn}} m_{J/\psi J/\psi}}{m_{J/\psi J/\psi}} \tag{4} \]

for two types of system parity $P = +$ and $P = -$, respectively, in which $p_{J/\psi}$ is the momentum of a final state $J/\psi$, and the factor $e^{i\phi_{mn}} m_{J/\psi J/\psi} = e^{i\phi_{mn}} m_{ij}$ is introduced to describe the energy dependence of the direct hadroproduction amplitude of intermediate charmonium pairs $H_{c}^{+}H_{c}^{-}$, as shown in Eq. (1). Here, it is worth noting that the coupling constant $g_{ij}$ involves two contributions, the production ratio and the transition from $H_{c}^{+}H_{c}^{-}$ to the di-$J/\psi$ channel. The $c_{0} = -1.5$ and $c_{0} = -1.0$ are extracted by fitting the LHCb data [13, 45]. Here, the involved intermediate channels $H_{c}^{+}H_{c}^{-}$ are related to the parity-even and parity-odd, respectively, and the parity-odd amplitude corresponds to the hadroproduction of a $P$-wave double $J/\psi$.

The line shape for the total invariant mass spectrum of producing a double charmonium $J/\psi J/\psi$ in high-energy proton-proton colliders can be written as

\[ A^{2} = |A^{2}_{J/\psi J/\psi}(m_{J/\psi J/\psi}) + \sum_{mn} e^{i\phi_{mn}} A_{mn}(m_{J/\psi J/\psi})|^2 \]

\[ + |A^{2}_{direct}(m_{J/\psi J/\psi}) + \sum_{mn} e^{i\phi_{mn}} A'_{mn}(m_{J/\psi J/\psi})|^2, \tag{5} \]

where $\phi_{mn}$ is the phase between direct contribution and the corresponding rescattering dynamical process, and a background term $A^{2}_{direct} = \frac{(g^{2}_{J/\psi J/\psi} m_{J/\psi J/\psi})}{8 \pi^2 m_{J/\psi J/\psi}}$ describes the direct production of double $J/\psi$ with $P = 1$. Generally, the coupled channel effect in $T$ matrix may bring some imaginary part term for amplitude, which can be partially absorbed in phase angle factor $e^{i\phi_{mn}}$. 

![FIG. 2. The comparison between the fitting results to the LHCb and new CMS data based on an extended dynamical mechanism, where two parity-even intermediate rescattering channels $J/\psi \psi(3686)$ and $\chi_{c0} \chi_{c1}$ are included.](image-url)
In addition, there may exist an inherent phase difference between the production vertex of different intermediate charmonium pairs. Here, it is worth mentioning that the \( J/\psi J/\psi \) spectrum production in high-energy \( pp \) collision is from a complex inclusive reaction \( pp \to J/\psi J/\psi X \), where the unitary may be violated. Here, we choose only the phase angle \( \phi^{mn} = 0 \) and \( \pi \) for the consideration of reducing the fitting parameters, which can relate to the constructive and destructive situation, respectively.

In the extended dynamical mechanism, there exists an integral singularity at the threshold of \( (m_i + m_j) \) appearing at the on-shell of two intermediate charmonia because of a square root branch point \( \sqrt{m_{J/\psi J/\psi} - m_i - m_j} \) from the scattering amplitude. From Eqs. (3) and (4), it can be seen that the extended dynamical amplitude returns to the single loop situation when \( C_{ij} L_{ij} < 1 \) as shown in Ref. [45], in which this integral singularity of amplitude will cause a nonresonant cusp line shape on the distribution of the \( m_{J/\psi J/\psi} \) and its peak position is almost exactly at the threshold of inducing the on-shell intermediate charmonium pairs. Interestingly, if the coupling constant \( C_{ij} \) is strong enough, the threshold cusp may transform into a pole structure, whose configuration should be quite novel and is totally different from the compact type of \( c\bar{c}c\bar{c} \).

III. WHAT CAN WE LEARN FROM THE DI-\( J/\psi \) SPECTRUM REPORTED BY CMS?

With the above preparations, we can study the di-\( J/\psi \) mass spectrum based on the extended dynamical model. In our previous research work, we have indicated that an underlying broad enhancement near threshold and the reported \( X(6900) \) structure in LHCb data can be reproduced well by the parity-odd channel \( \chi_{c1} \eta_c \) and parity-even channel \( \chi_{c0} \chi_{c1} \), respectively [15]. However, the authors in Ref. [46] found that the broad enhancement near threshold can also be explained by the destructive contribution from the parity-even channel \( J/\psi \psi(3686) \), whose threshold just exactly locates at an obvious dip position between two peaking structures. This fact means that the LHCb data cannot distinguish these two channel contributions. Fortunately, the new CMS measurement can reveal more critical information to clarify this problem, where more details on the line shape of novel fully charm enhancement structures were presented compared with previous LHCb data.

By checking the relevant experimental data of CMS, we found a new data accumulation in the vicinity of 6.6 GeV, which is not far from the threshold of the \( \chi_{c1} \eta_c \) channel. In order to demonstrate that this accumulation may be caused by the parity-odd contribution of \( \chi_{c1} \eta_c \) instead of \( J/\psi \psi(3686) \), we performed an independent fit to the CMS and LHCb data by considering two parity-even intermediate channels \( J/\psi \psi(3686) \) and \( \chi_{c0} \chi_{c1} \), whose fitting results are shown in Fig. 3. It can be seen that the line shape of the di-\( J/\psi \) invariant mass spectrum measured by LHCb can be reproduced well in the present scenario, which is consistent with the conclusion of Ref. [46]. However, it is apparent that the CMS data cannot be described well in the same scheme, especially for two energy regions with a large divergence. The first one is the energy range between 6.6 and 6.7 GeV, which just corresponds to the threshold of the rescattering channel \( \chi_{c1} \eta_c \). The second region is around 7.1 GeV. As a matter of fact, our former work has given the predictions for the existence of possible fully charm structures in this energy region although the LHCb experiment does not show any obvious hints [15] [15], where \( \chi_{c1} \chi_{c1} \), \( \chi_{c1} \chi_{c2} \) and \( \chi_{c2} \chi_{c2} \) contribute to the energy position of \( (7.03 - 7.13) \) GeV. Hence, in the following, we will explore whether the CMS data on this critical energy region of the double \( J/\psi \) mass spectrum can be reproduced by the inclusion of two new intermediate double charmonium channels \( \chi_{c1} \eta_c \) and \( \chi_{c2} \chi_{c2} \).

Based on the extended dynamical production mechanism, the complete theoretical analysis of the CMS experimental data of the invariant mass spectrum of \( J/\psi J/\psi \) is presented in Fig. 3. And the corresponding fitted parameters are summarized in Table I. One can see that the novel peaking structures shown in the CMS data can be reproduced well by the red solid line in the fit-I scheme, where the fitting \( \chi^2/d.o.f. = 0.657 \) is obtained. Specifically, the experimental data around 6.6 and 7.1 GeV can indeed be described by the contribution from the \( \chi_{c1} \eta_c \) and \( \chi_{c2} \chi_{c2} \) channel, respectively. This means that the CMS measurement provides definite evidence for confirming the contribution of parity-odd channel \( \chi_{c1} \eta_c \) in the \( J/\psi \)-pair mass spectrum for the first time. From

FIG. 3. The complete theoretical fit to the invariant mass distribution of \( J/\psi \) pair measured by the CMS Collaboration [60] within an extended dynamical mechanism. Here, two fitting schemes of fit I and fit II are presented, in which four characteristic intermediate channels \( \eta_c \chi_{c1} \), \( J/\psi \psi(3686) \), \( \chi_{c0} \chi_{c1} \) and \( \chi_{c2} \chi_{c2} \) are introduced.
Table I. The fitted parameters for reproducing the line shape of the CMS data within the fit-I and fit-II schemes.

| Parameters                  | Fit I               | Fit II              |
|-----------------------------|---------------------|---------------------|
| \( g_{\text{direct}}/g_{\text{direct}} \) | 0.0575 ± 0.0009    | 0.0699 ± 0.0010     |
| \( g_{n/\chi_{11}}/g_{\text{direct}} \) | 125 ± 26           | 28 ± 2.7            |
| \( g_{J/\psi(3866)}/g_{\text{direct}} \) | −26.1 ± 4.7        | −16.4 ± 1.7         |
| \( g_{n/\alpha_{\chi_{11}}}/g_{\text{direct}} \) | 32.9 ± 5.8         | 16.2 ± 1.4          |
| \( g_{s/\alpha_{2\chi_{2}}}/g_{\text{direct}} \) | −15.3 ± 6.1        | −12.3 ± 1.4         |
| \( C_{J/\psi(3866)} \) | −144 ± 14          | −82.3 ± 1.8         |
| \( C_{n/\chi_{11}} \) | 342 ± 107          | −21.3 ± 18.7        |
| \( C_{J/\psi(3866)} \) | −20 ± 40           | −32.0 ± 5.5         |
| \( C_{\chi_{0}/\chi_{11}} \) | 380 ± 54           | 20.0 ± 50.6         |
| \( C_{\chi_{0}/\chi_{2}} \) | 145 ± 175          | −41.4 ± 13.3        |
| \( \alpha \) (GeV) | 0.871 ± 0.046      | 1.813 ± 0.030       |

\( \chi^2/\text{d.o.f.} \) are 0.657 and 0.699, respectively. Their individual line shape on the invariant mass spectrum of double \( J/\psi \) can be found in Fig. 3(b), in which there is an obvious line shape difference between cusp and resonance solution. Although the resonance solution is from the best \( \chi^2 \) fitting for the experimental data, we must point out that it is difficult to understand such strong coupling constant \( C \) for a double charmonium scattering to charmonium pairs, where the long-distance interaction from the direct exchange of light medium mesons should be relatively suppressed due to the absence of light quark freedom in the fully heavy reaction system. Here, some interesting unknown non-perturbative dynamics should play important role, which may be reliably revealed by lattice QCD in the future.

Beforehand, we further perform an analysis of the fit-II scheme to CMS’s experimental data by assuming that the scattering channel \( J/\psi(3866) \) produces a threshold cusp structure and three resonance poles from the rescattering channels \( \chi_{11}\chi_{11}, \chi_{0}\chi_{11}, \) and \( \chi_{2}\chi_{2} \) all appear in the second Riemann sheet, whose pole positions are determined to be

\[
\begin{align*}
E_{\chi_{0}/\chi_{11}} &= (6.625 - 0.107i) \text{ GeV}, \\
E_{\chi_{0}/\chi_{2}} &= (7.050 - 0.089i) \text{ GeV}, \\
E_{\chi_{2}/\chi_{2}} &= (7.170 - 0.108i) \text{ GeV},
\end{align*}
\]

where superscript I and II represent the fit-I and fit-II scheme, respectively. It can be seen that these virtual pole effects produce the obvious threshold cusp structures.

We also studied the scattering lengths of each intermediate charmonium channel in the two fit schemes. The interaction property of double charmonia scattering can be reflected by scattering length \( a_0 \); i.e., positive \( a_0 \) and negative \( a_0 \) correspond to attractive and repulsive interaction in the absence of a bound state pole, respectively.

In both the fit-I and fit-II scenarios. By a pole analysis, we found that there are not any pole structures in the fit-II scheme and the corresponding central values of the coupling constants \( C_{\chi_{11},\eta_c} = -21.3, C_{J/\psi(3866)} = -32.0, C_{\chi_{0}/\chi_{11}} = 20.0 \) and \( C_{\chi_{2}/\chi_{2}} = -41.4 \) with cutoff \( \alpha = 1.813 \) shown in Table I will induce a threshold cusp line shape on the double \( J/\psi \) spectrum. This finding actually means that the threshold cusp or resonance pole solution cannot be definitely distinguished from the present experimental precision, which should depend on the concrete coupling strength of double charmonia scattering.

In addition to the resonance poles, ignoring small width effect from intermediate charmonium states, we found several virtual poles below the respective threshold in the two fit schemes, which are

\[
\begin{align*}
\epsilon^{I}_{J/\psi(3866)} &= 6.191 \text{ GeV}, \\
\epsilon^{I}_{J/\psi(2S)} &= 6.718 \text{ GeV}, \\
\epsilon^{II}_{J/\psi(3866)} &= 6.188 \text{ GeV}, \\
\epsilon^{II}_{J/\psi(2S)} &= 6.687 \text{ GeV}, \\
\epsilon^{II}_{\chi_{0}/\chi_{2}} &= 6.343 \text{ GeV}, \\
\epsilon^{II}_{\chi_{2}/\chi_{2}} &= 7.045 \text{ GeV},
\end{align*}
\]

where superscript I and II represent the fit-I and fit-II scheme, respectively. It can be seen that these virtual pole effects produce the obvious threshold cusp structures.
The di-$J/\psi$ mass spectrum. We expect that this mechanism can be confirmed in future precise experimental measurements, especially at run III of the LHC.

| TABLE II. The calculated center value of the scattering length for each intermediate channel by using parameters in the fit-I and fit-II schemes. |
| --- |
| Scattering length | Fit I (fm) | Fit II (fm) |
| $a_0(J/\psi J/\psi)$ | 2.25 | 1.64 |
| $a_0(\eta_c \chi_{c1})$ | 0.33 | 0.48 |
| $a_0(J/\psi\psi(3686))$ | 0.87 | 0.53 |
| $a_0(\chi_{c0}\chi_{c1})$ | 0.32 | 0.33 |
| $a_0(\chi_{c2}\chi_{c2})$ | 0.51 | 0.58 |

**IV. DISCUSSION AND CONCLUSION**

Very recently, the CMS Collaboration reported measurement results of the invariant mass spectrum of the $J/\psi$ pair from $pp$ collisions, where several peaking phenomena were observed $^{[60]}$. Compared with previously reported $X(6900)$ structure by LHCb $^{[13]}$, the new CMS measurement brings us more important information. In this work, we have studied these newly observed fully charm enhancement structures in an extended dynamical mechanism. Our basic idea is based on a reaction that different combinations of the intermediate double charmonia directly produced in high-energy proton-proton collisions are transferred into final states of $J/\psi J/\psi$. This reaction picture can be further extended to the contribution involving higher-order loops.

By employing the extended dynamical model to describe the line shape of the invariant mass spectrum of double $J/\psi$ newly measured by CMS, we have demonstrated that the contributions of all four characteristic intermediate channels $\eta_c\chi_{c1}$, $J/\psi\psi(3686)$, $\chi_{c0}\chi_{c1}$, and $\chi_{c2}\chi_{c2}$ are required in order to reproduce the CMS distribution. This fact means that these new features from the CMS measurement provide strong evidence to support the dynamical interpretation for the observed fully charm enhancement structures. Furthermore, we adopted two fitting schemes to explore the origin of the fully charm peaking phenomena in the dynamical mechanism, in which we concluded that the threshold cusp and resonance pole solution cannot be distinguished from the present experimental precision.

In order to better solve this problem, we suggest two accessible ways here. One can find there exist many combinations of on-shell charmonium pairs in the di-$J/\psi$ mass spectrum because of an approximate heavy quark symmetry in the charm sector, whose interference effect usually causes difficulty of identifying the origin of these novel fully charm enhancements. Thus, an available method is to measure the invariant mass spectrum of the intermediate channel itself in hadron colliders, such as $\eta_c\chi_{c1}$, $J/\psi\psi(3686)$, $J/\psi\psi(3770)$, $\chi_{c0}\chi_{c1}$, and so on, where the line shape measurement should be helpful to identify the threshold cusp or resonance solution because the contributions of some off-shell channels should be suppressed by the phase space. We noticed that the ATLAS Collaboration recently released the preliminary result of the $J/\psi\psi(3686)$ mass spectrum, which just can test our dynamical production mechanism of double charmonia. In Fig. 5 we presented the comparison between the ATLAS data and our predictions for the line shape of the invariant mass spectrum of $J/\psi\psi(3686)$ from the $J/\psi\psi(3686)$ channel in two parameter schemes.
The second approach is to quantitatively estimate the magnitude of coupling strength of double charmonia scattering by the first principle lattice QCD theory. Coincidentally, we noticed recent research work to discuss the property of a dibaryon scattering of $\Omega_{cc}^{--}\Omega_{cc}^{++}$ near unitarity region from lattice QCD [92], which is another novel fully charm system. We hope that our analysis in this work can stimulate activities from lattice group to study double charmonia scattering, which should be worth expecting in the future.

Finally, we strongly call for more theoretical and experimental studies to concentrate on this kind of novel fully heavy system, which should be a new important frontier to investigate nonperturbative behavior of strong interaction in the future.

ACKNOWLEDGEMENTS
