5-Hydroxytryptophan (5-HTP) plays an important role in the regulation of emotion, behavior, sleep, pain, body temperature, and other physiological functions. It is used in the treatment of depression, insomnia, migraine, and other diseases. Due to a lack of effective biosynthesis methods, 5-HTP is mainly obtained by natural extraction, which has been unable to meet the needs of the market. Through the directed evolution of enzymes and the introduction of substrate supply pathways, 5-HTP biosynthesis and yield increase have been realized. This review provides examples that illustrate the production mode of 5-HTP and the latest progress in microbial synthesis.

Keywords: 5-hydroxytryptophan, tryptophan hydroxylase, L-trp, biosynthesis, tetrahydrobiopterin

INTRODUCTION

5-Hydroxytryptophan (5-HTP) is a natural amino acid (AA) that does not participate in protein synthesis. It is derived from tryptophan (trp), and the hydrogen atoms at the 5'-position on the benzene ring of trp are replaced by hydroxyl groups. 5-HTP appears as a fine white powder that is insoluble in water, but is soluble in alcohol. In mammals, 5-HTP is the precursor of the neurotransmitter serotonin and the amine hormone melatonin. It has been successfully used in the treatment of depression, insomnia, migraines, and other diseases due to its regulatory effects on sleep, pain, appetite, and other physiological functions (Figure 1) (Birdsall, 1998). 5-HTP is widely used for psychotropic drugs and weight loss in developed countries. Health-care drugs with 5-HTP as the main ingredient are used in 20 countries. According to the 2014 Thomson Reuters market research report, the annual global sales of 5-HTP were $7.5 million, an increase of 50% over the same period the previous year, with an annual consumption of 1.6 tons.

At present, 5-HTP is mainly extracted from natural products, specifically from the seeds of the African plant *Griffonia Simplicifolia*, but this method of extraction is unable to meet the market demand due to high cost and a lack of raw materials. Chemical synthesis does not depend on natural products. However, it is not currently possible to synthesize 5-HTP economically and effectively due to the tedious steps involved and harsh conditions required. With the development of biotechnology in bioinformatics, genetics, metabolic engineering, biochemistry, protein engineering, and so on, new strategies are available for the use of microorganisms to synthesize 5-HTP. The production of 5-HTP by the microbial method has the advantages of short production cycle, continuous production and mild reaction conditions. Among the organisms used for this method, *Escherichia coli* is a model strain of prokaryotes with clear genetic information and well-established fermentation conditions, making it particularly well-suited for use as a host cell for the study of 5-HTP biosynthesis.

Frontiers in Bioengineering and Biotechnology | www.frontiersin.org 1  February 2021 | Volume 9 | Article 624503
Chronic headaches are caused by high-purity 5-HTP. In addition, 5-HTP can increase the content of 5-hydroxyindoleacetic acid (a serotonin-decomposition product) in the cerebrospinal fluid of the central nervous system (Sano, 1972). In addition, the content of 5-hydroxyindoleacetic acid (a serotonin-decomposition product) in the cerebrospinal fluid of the patients significantly increased after 5-HTP intake, indicating that 5-HTP was successfully converted to serotonin after entering the central nervous system (Takahashi et al., 1975).

Dieting leads to a sharp decrease in serotonin levels in the serum and brain, and a decrease in serotonin leads to gluttonous gluttony. 5-HTP can prevent dieting induced decrease in serotonin in patients with obesity, thus reducing appetite and assisting with weight loss (Ceci et al., 1989; Cangiano et al., 1991, 1992). In addition, 5-HTP can also improve the symptoms of fibromyalgia, including pain, morning stiffness, anxiety, and fatigue (Caruso et al., 1990; Sarzi Puttini and Caruso, 1992; Nicolodi and Sicuteri, 1996). Chronic headaches are caused by reduced serotonin levels in the body. 5-HTP has successfully been used to prevent various types of chronic headaches, including migraines, tension headaches, and adolescent headaches (Bono et al., 1982; Longo et al., 1984; Benedittis and Maseei, 1985; Titus et al., 1986; De Giorgis et al., 1987; Maissen and Ludin, 1991; Nicolodi and Sicuteri, 1996). In addition, 5-HTP can increase the rapid eye movement sleep period to improve sleep quality for the treatment of insomnia.

**PRODUCTION OF 5-HTP**

The anabolic-metabolic engineering design for 5-HTP has gained considerable attention and has been widely studied because of its important physiological functions and huge market demand. At present, the main methods for producing 5-HTP are natural product extraction, chemical synthesis, and microbial fermentation. Among these methods, natural product extraction remains the primary method for the commercial production of 5-HTP. While microbial synthesis and catalysis provide a fast and environmentally friendly alternative to produce natural compounds of medical value.

**Natural Extraction of 5-HTP**

5-HTP is widely present in the seeds of legumes, with the seeds of African plant *Griffonia Simplicifolia* having the highest content. The leaves and seeds of the Ghanaian tree have been used as medicine in Africa since ancient times to treat wounds, kidney disease, and for enemas. The paste made from its bark is also used to treat skin diseases, in which the main active ingredient is 5-HTP. Lemaire and Adosraku extracted 5-HTP using the alcohol method, and found that it constituted 20.83% of the fresh weight of the seeds (Lemaire and Adosraku, 2010). After optimization of the extraction temperature, the content of 5-HTP in the extract increased from 6.37 to 8.98% and the purity reached 92% (Addotey, 2009). Using ultrafiltration membrane separation technology, the 5-HTP transfer rate was found to be 83.5%, and purity reached 90.5% (Qin et al., 2014). In addition, high-purity 5-HTP was also obtained from flower beans by ultrasonic method (Duan et al., 2017).

However, the natural source of 5-HTP is relatively singular. There is a shortage of raw materials and costs are continually increasing with the increase of exploitation. The increasing market demand is impossible to meet through natural extraction alone. Therefore, there has recently been an increasing number of studies regarding the production of 5-HTP via chemical synthesis and biological fermentation.

**Chemical Synthesis of 5-HTP**

5-HTP is synthesized by Michael addition reaction using 5-bromoindole 3-bromo-2-hydroxyimino-propionate as the substrate. The addition reaction connects the side chain of 2-hydroxyimino-propionate to the 3-position of the indole. Subsequently, the reduction reaction, hydrolysis reaction, and resolution steps are introduced to obtain 5-HTP (Fuchun et al., 2013). In an invention patent, Raney-Ni and ZnO were added to an autoclave as catalysts. Trp, glycolic acid, and hydrochloric acid were reacted in the autoclave for 0.25–6h, then filtered and dried to obtain poly-hydroxy-trp drying substance. The dried substance was then reacted with trp, sodium hydroxide, and deionized water. The 5-HTP crystals were finally obtained after filtration, chromatography and cooling crystallization (Rihe, 2010). Wenhui and colleagues first demonstrated the methyl (ethyl) esterification of L-trp to form tryptophan methyl...
expressed human TPH in \( \text{E. coli} \). There are two subtypes of TPH \( \text{Zhang et al., 2016} \).

Kino et al., 2009 studied the active center \( \text{Ikemoto et al., 2002} \). expressed mutant PAH or TPH \( \text{Windahl et al., 2008} \).

Yamamoto et al. (2003) expressed rabbit-derived TPH in \( \text{E. coli} \).

(ethyl) ester hydrochloride. 5-HTP was obtained after desalting, acetylation, redox, deacetylation, and other reactions. After cooling and crystallization, 5-HTP crystals were obtained. The purity of the product was 99.2% and the overall yield was 45% \( \text{Wenhui et al., 2013} \).

The chemical method for the synthesis of 5-HTP is tedious, harsh, and costly. It uses a variety of organic reagents, resulting in serious environmental pollution. Therefore, this method is not suitable for the large-scale production of 5-HTP.

### Biosynthesis of 5-HTP

5-HTP production by biological methods is favored due to its advantages, such as a short production cycle, continuous production, and mild reaction conditions. In vivo, 5-HTP is obtained by L-trp hydroxylation catalyzed by trp hydroxylase (TPH) using L-trp as a substrate (Figure 2). TPH is a monoxygenase that uses trp and oxygen as substrates, and tetrahydrobiopterin (BH\(_4\)) and Fe\(^{2+}\) are required as cofactors in its catalytic process \( \text{Kappock and Caradonna, 1996; Fitzpatrick, 1999; Olsson et al., 2010; Roberts and Fitzpatrick, 2013} \).

### METABOLIC ENGINEERING STRATEGY FOR 5-HTP SYNTHESIS

In vivo, 5-HTP is produced from L-trp and the reaction is catalyzed by TPH, which uses L-trp and O\(_2\) as substrates and requires BH\(_4\) and Fe\(^{2+}\) as cofactors. The activity of TPH, the supply of L-trp, and the synthesis and regeneration of BH\(_4\) are three key factors that restrict 5-HTP synthesis.

### L-Tryptophan Hydroxylase (TPH)

TPH, phenylalanine hydroxylase (PAH), and tyrosine Hydroxylase (TH) are perin-dependent aromatic AA hydroxylases (AAAHS) \( \text{Windahl et al., 2008; Olsson et al., 2010} \). Moreover, these three hydroxylases have substrate interconnectedness, and each hydroxylase can catalyze the hydroxylation of these three aromatic AAs \( \text{Olsson et al., 2010; Roberts and Fitzpatrick, 2013} \). There are two subtypes of TPH in mammals: TPH1 and TPH2 \( \text{Walther et al., 2003} \). TPH1 was discovered first and studied in depth. In adults, TPH1 is mainly expressed in non-nerve cells \( \text{Murphy et al., 2008} \).

Walther et al. found that the brains of mice could still produce serotonin normally after knocking out the TPH1 gene. Further studies found another TPH, TPH2, in the brains of mice \( \text{Walther et al., 2003} \). TPH1 and TPH2 have 71% AA sequence homology. TPH2 is mainly responsible for the synthesis of serotonin in the central nervous system, including the frontal area, thalamus, hippocampus, amygdala, and hypothalamus, whereas TPH1 is mainly expressed in the pineal gland and the gut and is responsible for the synthesis of serotonin in other parts of the body, such as the heart, lungs, and kidneys \( \text{Walther and Bader, 2003; Walther et al., 2003; Patel et al., 2004; Zhang et al., 2004; Sakowski et al., 2006} \).

First, TPH was heterologous expressed in \( \text{E. coli} \), and its structure, enzymatic properties, and catalytic mechanism were studied. \( \text{Windahl et al., 2008} \) studied the active center structure of chicken TPH1. The Fe\(^{2+}\) coordination structure was found to belong to the heme-independent general Fe\(^{2+}\) coordination structure. The Fe\(^{2+}\) coordination is a distorted trigonal bipyramidal coordination with His273, His278, Glu318, and an imidazole ligand. The substrate trp binds to the hydrophobic pocket of the active center. This hydrophobic pocket is composed of Tyr236, Thr266, Pro267, Glu268, Pro269, His273, Phe314, Phe319, and Lie367 \( \text{Windahl et al., 2008} \).

McKinney et al. (2004) expressed human TPH in \( \text{E. coli} \) and yeast expression system. They found that the soluble expression of TPH could be enhanced by fusion expression with maltose-binding protein. The fusion expressed TPH’s enzyme activity and affinity with L-trp was significantly improved. \( \text{Moran et al. (1998) expressed rabbit-derived TPH in E. coli. It was found that the soluble expression was significantly increased after removing 101 AAs at the N-terminal and 28 AAs at the C-terminal. Interestingly, this mutated TPH exists in the form of a monomer rather than a tetramer. Kino et al. (2009) found that Leu101 and Trp180 from the active center of Pseudomonas aeruginosa PAH exerted effects on substrate specificity and hydroxylase activity. The enzyme catalytic rate constant, \( K_{\text{cat}} \), increased 5.2 times after mutation at these two sites \( \text{Kino et al., 2009} \).} \)

### Synthesis and Regeneration of BH\(_4\)

One difficulty in using \( \text{E. coli} \) to produce 5-HTP is that it does not synthesize the coenzyme BH\(_4\), which is essential for TPH. \( \text{E. coli} \) can synthesize analogs of BH\(_4\), tetrahydromonapterin (MH\(_4\)) \( \text{Ikemoto et al., 2002} \). PAH of Pseudomonas aeruginosa can use MH\(_4\) as a coenzyme to hydroxylate L-phenylalanine to L-tyrosine. Zhang et al. (2016) expressed mutant PAH or TPH in Saccharomyces cerevisiae to catalyze the production of 5-HTP from L-trp. The activities of PAH and TPH in the hydroxylation of trp with MH\(_4\) and BH\(_4\) as cofactors were compared. The results showed that the hydroxylation activity of TPH using BH\(_4\) as a cofactor was 17 times higher than that of PAH using MH\(_4\) \( \text{Zhang et al., 2016} \).

With an in-depth understanding of the biosynthetic pathway of BH\(_4\), Yamamoto et al. (2003) synthesized BH\(_4\) through the heterologous expression in \( \text{E. coli} \). The synthetic pathway of

![Figure 2](image-url)
BH4 is shown in Figure 2. The production capacity of GTP (the precursor of BH4) was increased by mutation breeding (Perkins et al., 1999). By optimizing the activity of GCHI (the enzyme that catalyzes the first step of BH4 biosynthesis) from different sources, 4 g/L BH4 was obtained under fed-batch fermentation (Yamamoto et al., 2003).

Kino et al. (2009) first expressed the mutagenic TPH in E. coli and synthesized 0.8 mM of 5-HTP by adding BH4 as a substrate. Subsequently, the BH4 regeneration pathway and glucose dehydrogenase from Bacillus subtilis were introduced to increase the utilization rate of BH4. The yield of 5-HTP increased to 2.5 mM under these conditions (Table 1) (Kino et al., 2009; Hara and Kino, 2013). Knight et al. (2013) introduced the mammalian BH4 synthesis pathway and regeneration pathway into E. coli and co-expressed it with rabbit-derived TPH1. When L-trp was used as the substrate, the yield of 5-HTP reached 198 mg/L (Knight et al., 2013). Although 5-HTP synthesis was achieved by introducing the synthesis and regeneration pathway of BH4, the yield of 5-HTP was low and additional L-trp was needed, indicating that it is not a suitable method for mass production.

### Optimization of trp Supply

5-HTP yield can be increased by increasing TPH activity and introducing BH4 synthesis and regeneration pathways. Mora-Villalobos and Zeng (2017) mutated the aromatic amino acid hydroxylase of Cupriavidus taiwanensis and obtained the trp preference mutant enzyme CgAAAHHW192F. The mutated enzyme was co-expressed with the BH4 regeneration pathway in E. coli. Additionally, 5 mM trp could be transformed into 2.5 mM of 5-HTP by shaking flask culture for 24 h. After converting this pathway into L-trp producing bacteria, the synthesis of 5-HTP from glucose was realized. The flask yield was 100 mg/L in 60 h, and the batch fermentation yield was 962 mg/L (Mora-Villalobos and Zeng, 2018).

Wang et al. (2018) introduced human TPH into E. coli BL21, and co-expressed it with the synthetic and regenerative pathways of human BH4. The engineered bacteria hydroxylated 2 g/L trp to produce 1.24 g/L 5-HTP. The authors further introduced the trp synthesis pathway into the recombinant E. coli to realize the biosynthesis of 5-HTP. After the optimization of culture conditions, the yield of 5-HTP was further increased by 13 times to 314.8 mg/L. After module optimization, which included: (a) enzymatic modification to improve the hydroxylation activity of TPH, (b) reduction of the copy number of the trp synthesis gene, and (c) regulation of the promoter strength of genes involved in BH4 synthesis and regeneration, the yield of 5-HTP in the modified recombinant strain HTPL01-LMT was 1.29 g/L, 3.1-fold increase (Wang et al., 2018). To improve the stability of this system, the authors further integrated the L-trp biosynthesis pathway into E. coli genome and designed the promoter strength of the enzyme-coding gene, which catalyzes the first step of L-trp biosynthesis. To regulate the production of 5-HTP, they also regulated the copy number of the L-TPH coding gene plasmid. After these optimization steps, the amount of 5-HTP of shake flask fermentation increased to 1.61 g/mL, which was 24% higher than that of the original strain (Table 1) (Xu et al., 2020).

### Table 1: Overview of 5-HTP production by microorganism.

| Strains   | Modulations                                                                 | Titer (g/L)     | Cultivation                                | References                      |
|-----------|------------------------------------------------------------------------------|-----------------|--------------------------------------------|---------------------------------|

PROSPECTS

This review assesses the synthesis and research progress of 5-HTP. Compared with natural product extraction and chemical synthesis, biosynthesis has the advantages of a short cycle, continuous production and mild reaction conditions; thus, it has garnered considerable research attention. In the biosynthesis process, three aspects of optimization have been implemented to increase the output of 5-HTP: (a) improving the hydroxylation activity of the TPH enzyme by directed evolution, (b) introducing BH4 synthesis and the regeneration pathway, (c) introducing the trp synthesis pathway. To date, the yield of shake flask culture has reached 1.61 g/L.

Although 5-HTP production has increased 10-fold, remains insufficient for large-scale commercial production. The metabolic network is a complex system, and the efficiency of the target metabolic pathway is often affected by other metabolic pathways. Therefore, strain evolution and breeding for global metabolism may effectively improve the yield of the target product. Besides, high-density cell culture is another strategy for increasing the yield. Combined with the optimization of fermentation conditions and the improvement of cell culture density, the yield of 5-HTP could be further improved.

X-XL wrote the manuscript. BZ and L-ZA revised the Metabolic engineering strategy for 5-HTP synthesis section. All the authors contributed to the literature collection and data analysis, and approved it for publication.

FUNDING

This work was sponsored by the Shanghai Sailing Program (201YF1435500); the National Key R&D Program of China [Grant No. 2018YFC1604305]; the Shanghai Agriculture Applied Technology Development Program, China [Grant No. 2019-02-08-00-07-F01152]; the Natural Science Foundation of China [Grant No. 31871757]. Shanghai Technical Standard Program, China [18DZZ2202020]; Shanghai Engineering Research Center of food microbiology program [19DZZ2 81100].
