Pityriasis Lichenoides-like Mycosis Fungoides: Clinical and Histologic Features and Response to Phototherapy

Min Soo Jang, Dong Young Kang, Jong Bin Park, Joon Hee Kim, Kwi Ae Park, Hark Rim, Kee Suck Suh

Departments of Dermatology and Internal Medicine, Kosin University College of Medicine, Busan, Korea

INTRODUCTION

Mycosis fungoides (MF) is a neoplasm of the immune system. It is characterized by neoplastic T lymphocytes that home to the skin, producing characteristic lesions. Initially, various erythematous patches develop. These may be chronic, existing for several years until they become plaques, nodules, erythroderma, or tumors. It is often difficult to diagnose MF in its early phase, either because of overlapping features with benign inflammatory dermatoses or because of complex and occasionally conflicting clinicopathological findings. Clinicopathological variants of MF include hyperkeratotic-, bullous-, hypopigmented-, hyperpigmented-, porokeratotic-, granulomatous-, folliculotropic-, pustular-, verrucous-, erythrodermatous-, and pagetoid reticulosis. Pityriasis lichenoides (PL)-like MF is a rare subtype of MF that involves the same skin lesions as PL. Histologically, PL-like MF has the findings of MF. In this study, we investigated the clinical, pathological, and immunohistochemical features and treatment of PL-like MF.

MATERIALS AND METHODS

Patients

Fifteen patients, who had a clinical features of erythematous scaly, crusted macules, papules, or plaques (PL-like skin lesions) and histopathological features of MF according to the diagnostic criteria of the European Organization for Research and Treatment of Cancer (EORTC) were enrolled in this study. We excluded any patients who was not shown obvious histopathological features of MF. This study was approved by the institutional review board of Kosin University Gospel Hospital (IRB no. 91961-ABG-15-031).
Clinical assessment

We collected data regarding patient age, gender, disease duration, skin lesion distribution and shape, symptoms, TNM stage, and treatments. Clinical photographs were taken at every follow-up visit with the same digital camera (α 350; Sony, Tokyo, Japan), in the same position, and under controlled lighting conditions. Two independent dermatologists assessed patient responses to phototherapy based on the photographs. Their evaluation defined the clinical response as complete improvement (95% or greater clinical improvement); partial improvement (50% or greater clinical improvement); or no response (<50% clinical improvement). After treatment was complete, patients were followed every one to two months to detect recurrence.

Histopathological, immunohistochemical, and molecular evaluations

Biopsies were conducted on the PL-like lesions. Evaluation was based on the early MF findings of Pimpinelli et al. Typical MF and PL findings were observed. Paraffin-embedded tissue sections were stained using monoclonal antibodies against CD3, CD4, CD8, and CD30. In order to evaluate the gene rearrangement of the T cell gamma receptor, DNA was separated from 10 paraffin-embedded tissues for polymerase chain reaction (PCR).

RESULTS

Clinical manifestations (Fig. 1, Table 1)

Of the 316 MF patients, 15 (4.7%) had PL-like MF. Twelve of the 15 patients (80.0%) were male, and three (20.0%) were female. The patient ages ranged from 4 to 59 years, with a mean age of 17.2 years. Eleven patients (73.3%) were 20 years old or younger and four patients (26.7%) were older than 20 years of age. The disease duration was defined as the length of time between the disease onset and the first hospital visit. It ranged from one month to five years, with a mean disease duration of 1.5 years. Ten of the 15 patients (66.7%) experienced itching, but the remaining five had no subjective symptoms. Two patients had diffuse PL-like lesions all over the body, including the face. Twelve had lesions on the trunk and extremities, and one had lesions only on his extremities. All patients had erythematous or brownish papules. According to the TNM classification, 14 (93.3%) patients had Stage IB, and one (6.7%) had Stage IA disease. None of the patients had lymph node or visceral organ involvement.

Histological findings (Fig. 2, Table 2)

The histological features of both MF and PL were observed in all 15 cases. Epidermotropism, “haloed” lymphocytes and atypical cells with hyperchromatic nuclei, were observed in all 15 cases (100%). Lymphocytes were found along the basal layer of the epidermis in 14 cases (93.3%). Intraepidermal lymphocytes, which are larger than dermal lymphocytes, were identified in 13 cases.
Table 1. Clinical data, treatment, outcomes, and follow-up of patients with PL-like MF

| Case | Age (yr) / sex | Location | Clinical findings | Symptom   | Duration (mo) | TNM/stage   | Treatment and response | Duration of f/u since diagnosis (mo) |
|------|----------------|----------|-------------------|-----------|--------------|-------------|------------------------|--------------------------------------|
| 1    | 4/M            | Trunk & extremities | Papules & scales, PL-like | Pruritic  | 24           | T2N0M0/IB   | PUVA→CR                | Loss to f/u                          |
| 2    | 7/M            | Trunk & extremities | Macules & papules, PL-like | Pruritic  | 12           | T2N0M0/IB   | PUVA→CR                | 106                                  |
| 3    | 8/M            | Trunk & extremities | Macules & papules, PL-like | Asymptomatic | 24           | T2N0M0/IB   | PUVA→CR                | 144                                  |
| 4    | 7/M            | Trunk & extremities | Papules & scales, PL-like | Asymptomatic | 1           | T1N0M0/IA   | No treatment            | 56                                   |
| 5    | 10/M           | Trunk & extremities | Macules & papules, PL-like | Asymptomatic | 36          | T2N0M0/IB   | NBUVB→CR               | 32                                   |
| 6    | 19/M           | Whole body        | Papules & scales, PL-like | Pruritic  | 14           | T2N0M0/IB   | NBUVB→CR               | 20                                   |

| 8    | 10/M           | Trunk & extremities | Macules & papules, PL-like | Pruritic  | 5            | T2N0M0/IB   | NBUVB→CR               | 30                                   |
| 9    | 59/M           | Trunk & extremities | Macules & papules, PL-like | Asymptomatic | 60          | T2N0M0/IB   | No treatment            | Loss to f/u                          |
| 10   | 5/M            | Whole body        | Macules & papules, PL-like | Pruritic  | 5            | T2N0M0/IB   | NBUVB→CR               | 11                                   |
| 11   | 25/F           | Trunk & extremities | Papules & patches, PL-like | Pruritic  | 2            | T2N0M0/IB   | NBUVB→CR               | 10                                   |
| 12   | 7/F            | Trunk & extremities | Macules & papules, PL-like | Asymptomatic | 1           | T2N0M0/IB   | NBUVB→CR               | 5                                    |
| 13   | 11/M           | Extremities       | Papules & plaques, PL-like | Asymptomatic | 20          | T2N0M0/IB   | NBUVB→CR               | 11                                   |
| 14   | 18/M           | Trunk & extremities | Papules, PL-like        | Pruritic  | 48           | T2N0M0/IB   | NBUVB→CR               | 9                                    |
| 15   | 24/F           | Trunk & extremities | Papules & patches, PL-like | Pruritic  | 12           | T2N0M0/IB   | NBUVB→CR               | 8                                    |

PL: pityriasis lichenoides, MF: mycosis fungoides, M: male, F: female, PUVA: psoralen+ultraviolet A, CR: complete remission, NBUVB: narrowband ultraviolet B, f/u: follow up.
Parakeratosis was identified in 11 cases (73.3%). Finally, six cases had Pautrier’s microabscesses (40.0%). There were also various histopathological findings in the dermis. Stuffed lymphocytes were observed in the dermal papillae in 14 cases (93.3%). Coarse collagen bundles were found in the papillary dermis in 13 cases (86.7%). Eleven cases (73.3%) had a psoriasiform lichenoid pattern. Perivascular cell infiltration was observed in all of the patients. In addition, erythrocyte extravasation, basal vacuolar change, and necrotic keratinocytes were identified in 14 (93.3%), 13 (86.7%), and 7 (46.7%) patients, respectively.

Immunohistochemical findings and molecular biological evaluation (Fig. 3, Table 3)

In most cases, the atypical lymphocytes expressed the CD3 antigen. In 12 cases (80.0%), CD8-positive T cells were more frequently observed than CD4-positive T cells. Two (patient 7, 10) of these 12 cases showed predominance of CD8-positive T cells in the dermis compared to CD4-positive T cells, and predominance of CD4-positive T cells in the epidermis compared to CD8-positive T cells. Thirteen patients had CD30-negativity of the lesion. PCR was used for T cell receptor \( \gamma \) gene rearrangement in 10 patients. Monoclonal findings were confirmed in eight patients (80.0%).

Treatments and courses (Table 1)

Narrowband ultraviolet B (NBUVB) and psoralen + ultraviolet B (PUVA) therapy was performed in 10 and 3 patients, respectively. All patients who received PUVA therapy showed complete improvement. Among them, one patient (patient 2) developed classic MF 10 years later and then had full improvement after NBUVB therapy. All patients treated with NBUVB also experienced full improvement. The follow-up period after diagnosis ranged from five months to 12 years, with a mean of 2.9 years. Among patients for whom follow up data were available, at the final follow up, eight of 10 patients (80.0%) in the NBUVB group remained relapse-free. None of the patients died from PL-like MF.

DISCUSSION

MF is classified according to its natural course and prognosis into early (stage IA, IB, and IIA) and advanced (stage IIB, III, and IV) stages. Early MF presents with a variety of patches and plaques without internal involvement, but may progress to a more advanced stage. Variant forms of MF, whose clinical and histological patterns differ from those of typical MF, have been reported. It is important to understand the characteristics of these variant forms.
PL-like MF, first reported by Ko et al. 3, is an MF subtype that is poorly understood. There are few prior studies addressing PL-like MF. All of the patients in our study were diagnosed with early MF. Those with PL-like MF are expected to have better prognoses than those with other variants including bullous, granulomatous, and folliculotropic forms. It is crucial that PL-like lesions are differentiated from those of PL, papular MF, and lymphomatoid papulosis (LyP) using histology. de Unamuno Bustos et al. 6 reported that PL, PL-like MF, papular MF, and LyP all produce papular lesions with histological MF patterns (Table 4). PL and PL-like MF have been described as having similar clinical and histological findings. Three of four patients were initially diagnosed with PL based on their clinical and histological associations; however, additional histological tests confirmed that they had PL-like MF 6. The important clinical differentiation between PL and PL-like MF is that PL spontaneously heals within several months. PL-like MF demonstrates histological features of both MF (Pautrier's microabscess, lymphocytes aligned along basal cells, intraepidermal lymphocytes larger than dermal lymphocytes, haloed lymphocytes, stuffed lymphocytes in the dermal papilla, coarse collagen bundles in the papillary dermis) and PL (necrotic keratinocytes, spongiosis, erythrocyte extravasation, and exocytosis of lymphocytes and neutrophils). In papular MF, there are symmetrically distributed chronic papular skin lesions on the trunk and extremities. However, it does not include PL findings, such as erythrocyte extravasation or necrotic keratinocytes. LyP is a histologically malignant but indolent cutaneous lymphoproliferative disorder characterized by a benign course of chronic, recurrent, or disappearing papular lesions. There are five histological types (A, B, C, D, and E) of LyP. Type B is similar to MF and involves atypical lymphocytes with hyperchromatic cerebriform nuclei on histology. Papular MF was recently suggested to be a subtype of LyP7. Alternatively, papular MF and LyP may actually be the same disease. LyP and PL often have similar clinicopathological findings. Therefore, the distinction between LyP and PL, especially pityriasis lichenoides et varioliformis acuta (PLEVA), can be particularly difficult. In the proper clinical setting, the presence of large atypical CD30+ cells favors the diagnosis of LyP. The malignant potential of PL is debated. There are some reports of malignant progression of PL to MF, particularly in children. The presence of large atypical PL-like MF subtypes may be associated with transformation to MF. Ritter et al. 10 reported that of 13 patients initially diagnosed with PL, six were ultimately diagnosed with MF. It is likely that these cases can be explained by misdiagnosis. It is crucial that PL-like lesions are differentiated from those of PL-like MF. All of the patients in our study were diagnosed with early MF. Those with PL-like MF are expected to have better prognoses than those with other variants including bullous, granulomatous, and folliculotropic forms.

### Table 2. The histopathologic findings of patients with PL-like MF

| Histologic features of conventional MF | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | Patient, n (%) |
|---------------------------------------|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----------------|
| Psoriasiform lichenoid pattern         | + | − | + | − | + | + | + | + | + | + | + | + | + | + | + | 11 (73.3) |
| Parakeratosis                          | + | + | + | − | + | + | + | + | + | + | + | + | + | + | + | 11 (73.3) |
| Pautrier's microabscess                | − | + | − | − | + | − | + | + | + | + | + | + | + | + | + | 6 (40.0)  |
| Lymphocytes aligned along basal cells  | + | + | + | + | + | + | + | + | + | + | + | + | + | + | + | 14 (93.3) |
| Epidermotropism                       | + | + | + | + | + | + | + | + | + | + | + | + | + | + | + | 15 (100)   |
| Intraepidermal lymphocytes larger than dermal lymphocytes | + | + | + | + | + | + | + | + | + | + | + | + | + | + | + | 13 (86.7) |
| "Haloed" lymphocytes                  | + | + | + | + | + | + | + | + | + | + | + | + | + | + | + | 15 (100)   |
| Atypical cells with hyperchromatic nuclei | + | + | + | + | + | + | + | + | + | + | + | + | + | + | + | 15 (100)   |
| Stuffing lymphocytes in the dermal papilla | + | − | + | + | + | + | + | + | + | + | + | + | + | + | + | 14 (93.3) |
| Coarse collagen bundles in the papillary dermis | + | + | + | + | + | + | + | + | + | + | + | + | + | + | + | 13 (86.7) |
| Histologic features of PL             | Basal vacuolar change       | + | − | + | − | + | + | + | + | + | + | + | + | + | + | 13 (86.7) |
| Necrotic keratinocytes                | − | + | − | − | + | − | + | + | + | + | + | + | + | + | + | 7 (46.7)   |
| Perivascular cell infiltration        | + | + | + | + | + | + | + | + | + | + | + | + | + | + | + | 15 (100)   |
| Extravasation of erythrocytes         | + | + | + | + | + | + | + | + | + | + | + | + | + | + | + | 14 (93.3) |

PL: pityriasis lichenoides, MF: mycosis fungoides.
Table 3. Immunohistochemical and genotypic findings in patients with PL-like MF

| Case | Immunophenotype | CD3 | CD4/CD8 ratio | CD30 | TCR-γ gene rearrangement |

Table 4. Differentiation of PL, PL-like MF, papular MF and type B lymphomatoid papulosis

|                  | Clinical findings                                      | Histopathologic findings                                                                 | Prognosis                   |
|------------------|--------------------------------------------------------|------------------------------------------------------------------------------------------|-----------------------------|
| PL               | Recurrent crops of scaly papules                       | Basal vacuolar change, necrotic keratinocytes, perivascular cell infiltration, erythrocyte extravasation | Usually good (spontaneous regression) |
|                  | +/- vesicles, pustules, ulcers, and crusts             | +/- minimal CD30⁺                                                                         |                             |
| PL-like MF       | Persistent reddish-brown scaly papular or macular eruptions | MF features (Pautrier’s microabscess, epidermotropism, haloed lymphocyte, etc.)           | Good                        |
| Papular MF       | Chronic and symmetrically distributed papular eruption  | CD4⁺ cells                                                                               | Previous history of patches or any other clinical features of MF? |
|                  |                                                        |                                            | Yes: poor                   |
|                  |                                                        |                                            | No: good                    |
| Lymphomatoid papulosis | Chronic, recurrent, self-healing, waxing and waning papules and ulcerated, crusted nodules | Large atypical CD30⁺ cells Especially Type B, similar or identical to MF features (atypical lymphocytes with hyperchromatic cerebriform nuclei) | Usually good (spontaneous regression) |

PL: pityriasis lichenoides, MF: mycosis fungoides.

MF patients had T-cell receptor (TCR) gene rearrangements. This suggests that TCR is not a very useful method of differentially diagnosing PL and PL-like MF. In this study, 10 patients underwent the tests, and 80% of PL-like MF cases were verified to exhibit monoclonality.

MF treatments are determined based on the presence of systemic conditions, age, and disease course. Skin-directed therapies, including phototherapy (PUVA, NBUVB) and topical chemotherapeutic agents (melphalan, nitrogen mustard, carmustine), are known to be effective, safe, and convenient, particularly in early MF. Also, UVA1 has a sensitive effect on neoplastic cells by increasing production of tumor necrosis factor-α, and it might be an effective treatment for MF.

Ozawa et al. found that NBUVB induces T cell apoptosis in inflammatory skin lesions and expresses cell toxicity. Based on this mechanism, NBUVB has been used to treat various inflammatory skin diseases, including psoriasis, atopic dermatitis, and lichen planus, which all involve T cell infiltration into the epidermis and dermis. NBUVB was also reported to inhibit T cell neoplastic proliferation and penetration into the upper dermis and effectively treated MF in Asian populations. Therefore, NBUVB can also be used for PL-like MF, which develops mostly in the early stage of MF and demonstrates neoplastic T cell infiltration into the epidermis and the upper dermis. PUVA is therapeutic because it induces tumor cell apoptosis and DNA damage, suppresses keratinocyte cytokine production, and depletes Langerhans cells. It has been widely used as an effective first-line treatment of early MF and as a supplementary treatment for advanced MF.

There are only a few studies that have addressed PL-like MF phototherapy. Most of these studies involved combination therapy; therefore, the effects of phototherapy alone are not fully understood. Wang et al. reported one case of complete response using topical corticosteroids. de Unamuno Bustos et al. reported three cases of combination therapy that included PUVA and one case of NBUVB therapy alone. They found that there was a partial response in the three cases of combination therapy, and a complete response in the PUVA-only case. One of the authors of this study reported cases of successful treatment of PL-like MF using PUVA. Including previous study data, three PUVA therapy patients and 10 NBUVB therapy patients demonstrated full improvement in this study. These findings suggest that phototherapy is sufficient for the treatment of PL-like MF. The mean follow-up period after diagnosis was 2.9 years. There have been cases of recurrence in one PUVA case and two NBUVB cases. According to long term follow-up data of this study, patients had favorable prognoses similar to other reports. PL-like MF is a rare type of early MF that mainly develops in young patients and some adult patients and has a favorable prognosis. Its presentation is similar to that of PL. de Unamuno Bustos et al. also reported four adult PL-like MF patients. Also, there is high possibility of misdiagnosis, so there could be more cases than reported. Therefore, a clear understanding of the diagnosis and follow-up are needed. Histological findings of both MF and PL are present in PL-like MF. Based on immunohistochemistry, there are more CD8-positive cells than CD4-positive cells in PL-like MF, characterized by a CD8+ cytotoxic pheno-
type, similar to the findings in PLEVA. This study involved Asian patients, who have not been studied extensively in this field. We observed that the disease occurred in adults and that NBUVB can be used for PL-like MF due to its inhibition of T cell neoplastic proliferation and penetration into the upper dermis. We also observed the favorable prognosis of this variant of MF by analyzing long-term follow-up data. PL-like MF lesions are easily misdiagnosed or confused with other papular skin diseases. Therefore, skin biopsy is required for accurate diagnosis.
