Upon antigen stimulation, naive CD4 T cells can differentiate into Th1, Th2, or the newly characterized Th17 effector cells, which rapidly produce IFN-γ, IL-4, or IL-17, respectively (1–4). The hallmark cytokine of Th1 cells is IFN-γ, which is instrumental for cell-mediated immunity. Th2 cells produce the prototypical cytokine IL-4, as well as IL-5 and IL-13, in controlling humoral immune responses. IL-17, collectively with other cytokines and chemokines released by activated Th17 cells, plays an important role in several inflammatory autoimmune diseases (5–10). Thus, proper regulation of Th differentiation is critical for controlling both cellular and humoral immune responses and for maintaining immune homeostasis.

The cytokines made by pathogen-activated cells of the innate immune system during T cell priming are key factors in promoting Th differentiation. It is known that type I or type II IFNs from activated NK cells or plasmacytoid DCs, collectively with IL–12 produced by APCs, direct CD4 T cells into the Th1 cell lineage. IL-4 present in the priming environment preferentially induces Th2 cell differentiation. TGF-β and IL-6 promote the development of Th17 cells that expand in response to IL-23 (11–13). The Th1 and Th2 cytokines IFN-γ and IL-4, respectively, can inhibit the production of the opposing types of cytokines by CD4 T cells and antagonize Th17 cell differentiation. Th cell fate has also been shown to be influenced by several other factors including TCR affinity, antigen dosage, co-stimulatory molecules, and the type of APC (14–17). However, it is not known whether T cell selection in the thymus affects Th cell fate in the periphery.

Recently, we and others have demonstrated that MHC class II–positive thymocytes can efficiently mediate the positive selection of CD4 T cells in mice (18, 19). Human thymocytes express MHC class II, and thymocyte-mediated CD4 T cell selection also occurs in the thymus. The online version of this article contains supplemental material.
T cell selection provides a mechanism for several documented observations that could not be otherwise explained (20–28). Therefore, in humans, CD4 T cells can be selected by two pathways, and the two CD4 T cell populations likely coexist in the periphery. Because mouse thymocytes do not express MHC class II, thymocyte-mediated selection has not been considered, and the role of this pathway in Th cell fate has been neglected.

We report in this study that thymocyte-selected CD4 (T-CD4) T cells differ from thymic epithelial cell (TEC)-selected CD4 (E-CD4) T cells in that they can rapidly produce both IL-4 and IFN-γ upon in vivo as well as in vitro TCR stimulation. When differentiated into effector cells under non-polarizing conditions, these T-CD4 T cells appear to be Th0 effector cells able to produce both Th1 and Th2 cytokines. Furthermore, they maintained the potential to produce the opposite type of cytokines when differentiated into Th1 or Th2 cell lineages.

T-CD4 cells made IL-4 shortly after stimulation and also produced Th2 cytokines under Th1-inducing conditions in a Stat6-independent manner. A high level of preformed IL-4 mRNA were detected in CD4 single-positive (SP) thymocytes if they are selected on thymocytes, which is at least partly caused by enhanced histone acetylation of the IL-4 locus. Finally, T-CD4 T cells seem to have a protective role during an airway challenge, suggesting a unique regulatory function of T-CD4 T cells during an immune response.

RESULTS

T-CD4 T cells rapidly produce both IL-4 and IFN-γ

We generated mice that express MHC class II in thymocytes (Fig. S1 A, available at http://www.jem.org/cgi/content/full/jem.20070321/DC1) and peripheral T cells by introducing the MHC class II transactivator (CIITA) as a transgene under control of the CD4 promoter (CIITA<sup>Tg</sup>) (29). CIITA is a transcription factor that is both necessary and sufficient for the expression of molecules that participate in MHC class II-restricted antigen presentation (30). Using these mice, we previously demonstrated that CD4 T cells can be positively selected via both cortical TECs (cTECs) and thymocytes (19). Therefore, CIITA<sup>Tg</sup> mice generate a mixed population of CD4 T cells that are selected on TECs or thymocytes, whereas the control (WT) mice have only TEC-selected CD4 T cells (19).

To distinguish between the two CD4 T cell populations present in CIITA<sup>Tg</sup> mice, we named them E- and T-CD4 T cells to reflect the cell type mediating selection (epithelial cell– and thymocyte-selected CD4 T cells, respectively).

To study whether CD4 T cell function is different depending on their selection pathway, we initially examined the cytokine production potential of T-CD4 T cells upon in vivo stimulation. Although we have reported that CD4 T cells prepared from CIITA<sup>Tg</sup> mice produced elevated IL-4, the cytokine production upon in vivo stimulation was not studied (29). WT and CIITA<sup>Tg</sup> mice were injected with an anti-CD3 antibody i.v., and the levels of serum IL-4 and IFN-γ were measured 2 h later. CIITA<sup>Tg</sup> mice that have T-CD4 T cells showed a dramatic increase in both cytokines, suggesting an effector phenotype of T-CD4 cells (Fig. 1 A). Consistent with the in vivo induction of IL-4 and IFN-γ production, splenic CD4 T cells from CIITA<sup>Tg</sup> mice expressed more IFN-γ and IL-4 than WT mice 5 h after stimulation in vitro (Fig. 1 B) (29). Moreover, splenic CD4 T cells from CIITA<sup>Tg</sup> mice had a greater potential to produce IL-4 and IFN-γ than WT mice after a 2-d stimulation in vitro (Fig. 1 C).

T-CD4 Th1 cells produce Th2 cytokines in addition to IFN-γ

Next, we investigated the effector function of T-CD4 T cells in comparison to E-CD4 T cells. For this set of experiments, we included CIITA<sup>+/+</sup>/CIITA<sup>Tg</sup>-/- mice that only generate T-CD4 T cells because of a deficiency of MHC class II expression in TECs (19). Because there are more peripheral CD4 T cells of the effector/memory type (CD4<sup>+</sup>CD45RB<sup>+</sup>) in CIITA<sup>Tg</sup> and CIITA<sup>Tg</sup>/CIITA<sup>Tg</sup>-/- mice than in WT mice (i.e., 42 ± 9%, 41 ± 7%, and 27 ± 6% among splenic CD4 T cells, respectively; Fig. S1 B), we sorted naïve CD4 T cells (CD4<sup>+</sup>CD45RB<sup>+</sup>) from these mice.
from total peripheral CD4 T cells (Fig. S2, available at http://www.jem.org/cgi/content/full/jem.20070321/DC1). Sorted naive cells were then differentiated under neutral (ThN)-, Th1-, or Th2-inducing conditions. ThN cells from WT mice produced a small amount of IFN-γ and almost undetectable levels of IL-4 (Fig. 2, A and B). In contrast, CIITA<sup>Tg</sup> cells made a lot more IFN-γ and IL-4 than WT cells. Moreover, CIITA<sup>Tg</sup>/CIITA<sup>−/−</sup> cells produced very high levels of both IFN-γ and IL-4 (Fig. 2, A and B). Th1 cells from WT mice predominantly made IFN-γ but not IL-4, whereas both CIITA<sup>Tg</sup> and CIITA<sup>Tg</sup>/CIITA<sup>−/−</sup> Th1 cells produced IL-4 in addition to IFN-γ (Fig. 2, A and B) (29). The amount of IL-4 was much greater in CIITA<sup>Tg</sup>/CIITA<sup>−/−</sup> than in CIITA<sup>Tg</sup> Th1 cells, whereas IFN-γ levels were comparable among the three. When we examined Th2 cells, both CIITA<sup>Tg</sup> and CIITA<sup>Tg</sup>/CIITA<sup>−/−</sup> Th2 cells produced more IL-4 than WT cells. Unlike Th1 cells, Th2 cells from CIITA<sup>Tg</sup> or CIITA<sup>Tg</sup>/CIITA<sup>−/−</sup> mice produced a moderately elevated level of IFN-γ. The intracellular cytokine staining (ICS) data supported the dual cytokine production by CIITA<sup>Tg</sup> and CIITA<sup>Tg</sup>/CIITA<sup>−/−</sup> cells with generally more cytokine-producing CIITA<sup>Tg</sup>/CIITA<sup>−/−</sup> cells (Fig. 2 B). Total CD4 T cells from the same mice showed a similar cytokine pattern as naive CD4 T cells (Fig. S3). Other Th2 cytokines, such as IL-5 and IL-13, were also increased in CIITA<sup>Tg</sup> or CIITA<sup>Tg</sup>/CIITA<sup>−/−</sup> CD4 T cells (unpublished data) (29). Because CIITA<sup>Tg</sup> and CIITA<sup>Tg</sup>/CIITA<sup>−/−</sup> CD4 T cells can express the opposite cytokines, even under Th1- or Th2-skewing conditions, and the Th1 cells expressed a relatively more prominent amount of IL-4, we subsequently focused on the characterization of Th2 cytokine production by T-CD4 Th1 cells.

**The thymocyte-mediated T cell selection pathway is responsible for the phenotype of T-CD4 T cells**

To further substantiate the role of the CD4 T cell selection pathway in cytokine production potential, we used BM chimeric mice. We previously showed that in the WT hosts (C57BL/6), CIITA<sup>Tg</sup> CD4 cells are developed on thymocytes as well as on cTECs, whereas in MHC class II–deficient hosts, CD4 cells are only selected on thymocytes (19). Using this principle, we generated and examined three types of chimeric

**Figure 2.** Th1 cells from T-CD4 T cells produce the Th2 cytokine IL-4 as well as IFN-γ. Sorted naive (CD45RB<sup>hi</sup>CD44<sup>lo</sup>) CD4 T cells from WT, CIITA<sup>Tg</sup>, and CIITA<sup>Tg</sup>/CIITA<sup>−/−</sup> mice were cultured under neutral, Th1-, or Th2-skewing conditions for 6 d, as described in Materials and methods. Differentiated cells were subsequently restimulated with plate-coated anti-CD3 overnight, and culture supernatants were collected and analyzed for IFN-γ and IL-4 production by ELISA (A). The error bars represent the mean ± SD. For intracellular cytokine analysis (B), differentiated neutral, Th1, or Th2 cells were restimulated with PMA plus ionomycin for 5 h, as described in Materials and methods. After fixation and permeabilization, the cells were stained with PE-conjugated anti–IFN-γ and allophycocyanin-conjugated anti–IL-4 and analyzed by FACS. Numbers in the dot plots represent the percentages of cytokine-positive CD4 T cells. All experiments were repeated at least twice.
mice: WT→B6, CIITA<sup>Tg</sup>→B6, and CIITA<sup>Tg</sup>→CIITA<sup>−/−</sup> mice, which generate E-CD4<sup>E</sup>, E- and T-CD4<sup>E</sup>, and T-CD4<sup>T</sup> cells, respectively. CD4 T cell reconstitution was comparable among all chimeras but was lacking in the control WT→CIITA<sup>−/−</sup> chimeric mice (Fig. S4, available at http://www.jem.org/cgi/content/full/jem.20070321/DC1). Total splenic CD4 T cells from the BM chimeras were skewed under Th1- or Th2-inducing conditions, and their cytokine-producing capacities were assessed by ICS. Th1 cells derived from CIITA<sup>Tg</sup>→B6 and CIITA<sup>Tg</sup>→CIITA<sup>−/−</sup> BM chimeric mice produced abundant IL-4 in addition to IFN-γ, with a consistently higher percentage of IL-4–producing Th1 cells from CIITA<sup>Tg</sup>→CIITA<sup>−/−</sup> mice (Fig. 3 A). In addition, the Th2 cell cultures from CIITA<sup>Tg</sup>→B6 and CIITA<sup>Tg</sup>→CIITA<sup>−/−</sup> chimeras that had T-CD4 T cells also produced greater numbers of IFN-γ–expressing cells than WT→B6 mice, whereas IFN-γ production by Th2 cells was variable among chimeras (Fig. 3 A). This variability in cells producing IFN-γ alone or IFN-γ together with IL-4 in WT→B6 mice seems to correlate with cell activation caused by the lymphopenic environment of the hosts (19) because these two populations are not present in WT mice (Fig. 2 B).

It was possible that the Th2 cytokine production by Th1 cells and enhanced IFN-γ production by Th2 cells from CIITA<sup>Tg</sup>→B6 and CIITA<sup>Tg</sup>→CIITA<sup>−/−</sup> BM chimeric mice was caused by CIITA expression rather than thymic selection differences. To determine whether CIITA expression itself regulates cytokine gene expression or whether thymic selection is indeed responsible for the phenotype, we tested BM from CIITA<sup>Tg</sup>→A<sup>β</sup><sup>−/−</sup> mice. Cells from CIITA<sup>Tg</sup>→A<sup>β</sup><sup>−/−</sup> mice express the CIITA transgene but not MHC class II because of a deficiency in the MHC class II structural gene A<sup>β</sup>. Thus, CIITA<sup>Tg</sup>→A<sup>β</sup><sup>−/−</sup> BM–originated thymocytes in the chimera cannot mediate T-CD4 T cell selection because they do not express MHC class II molecules (18, 19). As a consequence, all CD4 T cells developed in CIITA<sup>Tg</sup>→A<sup>β</sup><sup>−/−</sup>→B6 chimeras are selected on cTECs. If thymic selection determines cytokine expression potential, the resulting CIITA<sup>Tg</sup>→A<sup>β</sup><sup>−/−</sup>→Th1 and Th2 cells from the chimeric mice should not express IL-4 and IFN-γ, respectively. As shown in Fig. 3 B, the cytokine pattern of Th1 cells from CIITA<sup>Tg</sup>→A<sup>β</sup><sup>−/−</sup>→B6 chimeras was indistinguishable from that of WT→B6 chimeras. Therefore, the thymocyte-mediated T cell selection pathway, not CIITA expression per se, is responsible for the generation of IL-4–producing Th1 cells and IFN-γ–producing Th2 cells.

**Figure 3.** The CD4 T cell selection pathway is responsible for IL-4–producing Th1 cells. (A) WT→B6, CIITA<sup>Tg</sup>→B6, and CIITA<sup>Tg</sup>→CIITA<sup>−/−</sup> chimeric mice were generated as described in Materials and methods. 11 wk after reconstitution, splenic CD4 T cells were differentiated under Th1- or Th2-inducing conditions for 6 d. Differentiated cells were then restimulated with PMA and ionomycin and analyzed for IFN-γ and IL-4 production. (B) CIITA transgene expression in the absence of MHC class II cannot generate IL-4–producing Th1 cells. BM from WT, CIITA<sup>Tg</sup>, or CIITA<sup>Tg</sup>→A<sup>β</sup><sup>−/−</sup> mice were transplanted into lethally irradiated B6 mice. Differentiated Th1 or Th2 cells from the mice reconstituted for 3 mo were assayed for cytokine production by ICS. The percentage of positive cells in each quadrant is shown.
cannot restore the APC function of TECs at full capacity, whereas the same transgene expression in Aβ2-/- TECs can. Likewise, thymocytes expressing CIITA would be more efficient APCs than those expressing I-E only. Together with the different phenotype of I-E Tg mice on the Aβ2-/- or CIITA-/- background, it appears that the potency of antigen presentation of thymocytes and TECs dictates the direction of CD4 T cell selection toward the T- or E-CD4 T cell lineage.

To address this hypothesis, we constructed and tested several additional BM chimeras. The expression pattern of MHC class II, Ii, and H-2M in TECs and thymocytes in mice used in those experiments is shown in the Table S1 (available at http://www.jem.org/cgi/content/full/jem.20070321/DC1). As summarized in Table I, the results showed that if the predicted potency of thymocytes being APCs is greater than TECs (CIITA Tg/CIITA Tg, CIITA Tg → Aβ2-/-, CIITA Tg → CIITA-/-, I-E Tg → Aβ2-/-, and I-E Tg/CIITA Tg → Aβ2-/-) or equivalent to that of TECs (CIITA Tg, I-E Tg/CIITA Tg, and CIITA Tg → B6), CD4 T cells seem to be selected on thymocytes as efficiently as TECs, and the resulting CD4 T cells can express Th2 cytokines under Th1-inducing conditions. In contrast, CD4 T cells did not show the same phenotype when they were developed in mice in which TECs have a greater potential to present antigens than thymocytes (B6, I-E Tg, I-E Tg/Aβ2-/-, CIITA Tg/Aβ2-/- → B6, I-E Tg → B6, and I-E Tg/CIITA Tg → B6). Therefore, these data clearly demonstrate a strong correlation between thymocyte-mediated selection and the Th cell function of the resulting CD4 T cells.

Thymocyte-mediated selection pathway can override a requirement of Stat6 in Th2 cytokine expression

NKT cells that are selected on thymocytes produce IL-4 in a Stat6-independent manner (36, 37). Therefore, we asked whether IL-4 production by T-CD4 T cells requires Stat6. We have previously observed that CD4 T cells from CIITA Tg mice bred to Stat6-/- mice produced IL-4 (29). However, those data did not distinguish whether Stat6 independence is caused by thymic selection. Thus, we tested Stat6-/- CD4 T cells for their ability to produce IL-4 after being selected on thymocytes. For this experiment, we mixed two different sources of BM, as MHC class II-positive thymocytes can mediate the development of MHC class II-negative thymocytes in mixed BM chimeras (unpublished data) (18). Stat6-/- BM, together with WT or CIITA Tg (Stat6 +/-) BM, were cotransferred into B6 or Aβ2-/- hosts. To identify different populations of CD4 T cells, we used the congenic marker CD45. Splenic CD4 T cells from reconstituted animals were skewed under Th1- and Th2-polarizing conditions, and Th1 cells derived from Stat6 +/- BM (CD45.2+) and Stat6-/- BM (CD45.1+) were analyzed for cytokine production by ICS. As expected, Stat6 +/- cells from Stat6-/- + WT→B6 chimeric mice expressed IL-4 when they were differentiated to Th2 but not Th1 cells (Fig. 4 A, top group). When Stat6-/- cells were examined, both Stat6-/- + Th1 and Th2 cells from Stat6-/- + WT→B6 BM chimeras produced a negligible amount of IL-4. In contrast, if Stat6-/- were developed in the presence of CIITA Tg BM-derived thymocytes, Stat6-/- Th1 and Stat6-/- CD4 T cells produced IL-4 (Fig. 4 A, middle and bottom groups). Moreover, Stat6-/- CD4 T cells that were exclusively selected on thymocytes (Stat6-/- + CIITA Tg→Aβ2-/-) had a greater potential to express IL-4. Stat6 +/- cells made IL-4 after differentiation into either the Th1 or Th2 cell lineage when they were from both Stat6-/- + CIITA Tg→B6 and Stat6-/- + CIITA Tg→Aβ2-/- hosts. The Th2 cell cultures generated more IL-4-expressing cells than the Th1 cells (Fig. 4 A). We also examined cytokine production by freshly

Table I. Relationship of the potency of antigen presentation in BM chimeras and the Th cell phenotype

| Mice         | MHC II expression | li and H-2M | Predicted potency of antigen presentation | Th2 cytokine production by Th1 cells |
|--------------|------------------|-------------|------------------------------------------|-------------------------------------|
| B6           | TECs             | Thymocytes  | TECs                                     | Thymocytes                          |
| CIITA Tg     | +                | +           | +                                        | +                                   |
| CIITA Tg/CIITA Tg-/- | -            | -           | -                                        | -                                   |
| I-E Tg       | +                | +           | +                                        | +                                   |
| I-E Tg/Aβ2-/- | +              | +           | -                                        | -                                   |
| CIITA Tg→B6  | +                | +           | +                                        | +                                   |
| CIITA Tg→Aβ2-/- | -            | -           | +                                        | +                                   |
| CIITA Tg→CIITA Tg-/- | -         | +           | -                                        | -                                   |
| CIITA Tg→Aβ2-/-→B6 | +         | +           | +                                        | +                                   |

Mice indicated with → are BM chimeras. Cells expressing MHC class II, li, and H-2M are considered hypothetically more potent than the cells expressing MHC class II in the absence or in low levels of li and H-2M. Expression denoted with - includes cells that express none or a low level of the indicated molecules. = or > show an equivalent or a stronger potency of antigen presentation function, respectively. Th2 cytokine production was experimentally determined using ICS. N, no; Y, yes.
isolated Stat6−/− thymic and splenic CD4 T cells from mixed BM chimeras. Again, whenever the thymocyte-mediated selection pathway was available, Stat6−/− cells acquired the potential to express IL-4 (Fig. S5, available at http://www.jem.org/cgi/content/full/jem.20070321/DC1).

Because Stat6−/− CD4 T cells were differentiated together with Stat6+/+ CD4 T cells, it was possible that the IL-4 produced by CIITA+/ CD4 T cells could have skewed Stat6−/− CD4 T cells to produce IL-4. To test this possibility, purified splenic CD4 T cells from Stat6−/− mice were mixed in vitro with WT or CIITA+/ CD4 T cells and differentiated under Th1- and Th2-inducing conditions. Stat6+/+ cells showed the expected cytokine profile from both WT and CIITA+/ Th1 and Th2 cells (Fig. 4 B). However, Stat6−/− CD4 T cells that were codifferentiated with CIITA+/ CD4 T cells did not acquire the ability to express IL-4. (Fig. 4 B). Collectively, our data strongly suggest that T-CD4 T cells produce Th2 cytokines in a Stat6-independent manner.
NKT cells do not influence the phenotype of T-CD4 T cells

The rapid production of IFN-γ and IL-4, the Th0-like phenotype of T-CD4 cells, and the Stat6-independent IL-4 production by T-CD4 cells seem to be similar to that of NKT cells (36, 37). NKT cells play an important role in regulating both innate and adaptive immune responses through their prompt production of large amounts of cytokines, including IL-4 upon both in vivo and in vitro TCR stimulation. Therefore, we investigated whether NKT cells contribute to IL-4 expression in T-CD4 T cells using CIITA<sup>Tg</sup> mice lacking CD1d (CIITA<sup>Tg</sup>/CD1d<sup>−/−</sup>), which is necessary for NKT cell development (38).

Primarily, when in vivo cytokine production was analyzed, a lack of CD1d and thus a deficiency in NKT cells did not alter the ability of CIITA<sup>Tg</sup> mice to produce IL-4 in response to short in vivo stimulation (Fig. 5 A). In addition, CD1d deficiency did not compromise the IL-4 production by CIITA<sup>Tg</sup> Th1 cells, thymocytes, and peripheral CD4 T cells upon in vitro stimulation (Fig. 5 B and not depicted). Therefore, CD1d-restricted NKT cells do not contribute to the Th2 cytokine–producing potential of T-CD4 T cells.

Preformed IL-4 mRNA in T-CD4 cells

IL-4 expression in freshly isolated CIITA<sup>Tg</sup> CD4 T cells (Fig. S5) (29) suggested that the chromatin structure at the IL-4 locus might already be differentially modified. To test this, we performed a chromatin immunoprecipitation (ChIP) assay to analyze the acetylation status of histone H3 at the IL-4 intronic enhancer (IE) that has been shown to be hyperacetylated in differentiated Th2 cells (39–41). Naive CD4 T cells were purified from total peripheral CD4 cells obtained from WT and CIITA<sup>Tg</sup> mice by FACS sorting and subjected to the ChIP assay. In naive CD4 T cells, histone H3 at this regulatory region was indeed hyperacetylated compared with the WT cells (Fig. 6 A, top). The modified IL-4 locus in naive cells raised the possibility that a similar change might have occurred in the thymus. Indeed, purified CD4 SP thymocytes from CIITA<sup>Tg</sup> mice showed a small but consistent increase in H3 acetylation (Fig. 6 A, bottom). Moreover, this small change correlated with IL-4 gene transcription even in the absence of stimulation, as the amount of IL-4 transcripts was greater in freshly isolated CIITA<sup>Tg</sup> CD4 SP cells than in control cells (Fig. 6 B). The level of IFN-γ mRNA in those CIITA<sup>Tg</sup> thymocytes was variable and did not show a consistent increase (unpublished data). Consistent with the RNA data, NK1.1<sup>+</sup> CD4 SP cells produced a small but reproducibly higher percentage of IL-4–expressing cells in CIITA<sup>Tg</sup> and CIITA<sup>Tg</sup>/CIITA<sup>−/−</sup> but not WT mice (Fig. 6 C). The IL-4 producers were all CD44<sup>hi</sup>, which is similar to IL-4–producing thymic NKT cells (unpublished data). We also examined Stat6<sup>−/−</sup> thymocytes prepared from mixed BM chimeric mice and found that Stat6<sup>−/−</sup> thymocytes produced IL-4 when they were selected on thymocytes (Fig. S5 A). Collectively, our results indicate that the IL-4 locus in CD4 T cells that are selected on thymocytes is programmed for increased expression before Th cell differentiation.

T-CD4 T cells can dampen allergen-induced airway inflammation

To investigate what role T-CD4 T cells play during an immune response in vivo, we used an antigen-induced airway inflammation model of asthma. CIITA<sup>Tg</sup> and WT mice were sensitized with chicken OVA and subsequently challenged with aerosolized OVA to induce inflammation in the respiratory tract. Mice were then killed to measure several parameters that are indicative of airway inflammation. We first examined the number of total cells in the bronchoalveolar lavage fluid (BALF). As shown in Fig. 7 A, the total cell numbers in BALF from OVA-challenged mice were decreased in CIITA<sup>Tg</sup> mice. Infiltration of eosinophils in the lung tissue is one of the cardinal features of asthma and serves as a simple readout for airway inflammation. In agreement with the total BALF cell numbers, CIITA<sup>Tg</sup> mice had significantly fewer BALF eosinophils than WT mice (Fig. 7 B). Neutrophilic infiltration in BALF was also reduced in CIITA<sup>Tg</sup> mice (Fig. 7 B). The percentage

Figure 5. NKT cells are not responsible for the IL-4–producing potential of T-CD4 Th1 cells. (A) Age-matched WT, CIITA<sup>Tg</sup>, CD1d<sup>−/−</sup>, and CIITA<sup>Tg</sup>/CD1d<sup>−/−</sup> mice were injected with 10 μg anti-CD3 antibody and killed 2 h later. The circulating IL-4 level in the serum was determined by ELISA. The error bars represent the mean ± SD of IL-4 measurements in the indicated mice. (B) CD4 T cells from CIITA<sup>Tg</sup> mice that were sufficient or deficient in CD1d expression were examined for their cytokine production profile by ICS after Th1 or Th2 cell differentiation. WT or CIITA<sup>Tg</sup> littermates on the CD1d<sup>−/−</sup> background were used as controls. Data are representative of at least two independent experiments. The percentage of positive cells in each quadrant is shown.
of monocytes was significantly higher in CIITA<sup>Tg</sup> than in WT mice, whereas the level of lymphocytes was comparable between WT and CIITA<sup>Tg</sup> mice (Fig. 7 B). Hematoxylin and eosin (H&E) staining of lung tissue sections also supported the difference in eosinophil infiltration between the two groups of mice (Fig. 7 C). In addition, OVA-specific IgE levels in serum were decreased in CIITA<sup>Tg</sup> mice (Fig. 7 D). We further examined the expression of several cytokines involved in airway inflammation. The lung tissue from OVA-sensitized and challenged CIITA<sup>Tg</sup> mice had significantly more IFN-γ but less IL-13 and IL-17 transcripts compared with the WT control mice. The IL-4 and IL-5 mRNA levels were comparable between the two groups (Fig. 7 E). Collectively, T-CD4 T cells seem to play a protective role during airway inflammation, which was associated with a distinct Th effector cytokine production profile at the site of inflammation.

**DISCUSSION**

In this study, we have shown that the thymic selection process plays an important role in the cytokine production potential of CD4 T cells. Hence, unlike E-CD4 T cells, T-CD4 T cells secrete both Th1 and Th2 cytokines shortly after stimulation. Remarkably, IL-4–producing cells can develop in the absence of Stat6 when CD4 T cells are selected on thymocytes. In addition, T-CD4 T cells can produce IL-5 and IL-13 in the absence of IL-4 (29). These observations are consistent with our data showing that the IL-4 locus, possibly including the IL-5 and IL-13 loci, is already remodeled in T-CD4 T cells such that the IL-5 and IL-13 genes are readily transcribed without IL-4.

Currently, it is not known how the thymic selection process regulates Th cell fate. Many factors are known to influence Th cell differentiation of conventional CD4 T cells, and the IL-4–Stat6 signaling pathway is critical for the differentiation of Th2 effector cells (14–17, 42–44). Stat6 activates GATA3, the master regulator of Th2 cells, which subsequently mediates chromatin remodeling accompanied by an increased level of histone hyperacetylation at the IL-4 locus. Although we could detect enhanced histone H3 and H4 acetylation at the IL-4 IE in both CD4 SP thymocytes and naive CD4 T cells from CIITA<sup>Tg</sup> mice, we found little difference in GATA3 expression in CIITA<sup>Tg</sup> cells as compared with WT controls (unpublished data). Consistent with this finding, we showed that Th2 cytokine production by T-CD4 T cells does not totally depend on the Stat6 signaling pathway.

Collectively, T-CD4 T cells seem to play a protective role during airway inflammation, which was associated with a distinct Th effector cytokine production profile at the site of inflammation.
cytokines such as IFN-γ and IL-4 cytokines upon TCR stimulation. It was shown that during thymic development, the IFN-γ and IL-4 loci in NKT cells are modified by histone acetylation and both genes are constitutively transcribed, which correlates well with the capacity of NKT cells to rapidly produce cytokines (37). However, T-CD4 T cells are distinct from NKT cells (19), and their phenotype is not influenced by CD1d-restricted NKT cells.

T cells selected on thymocytes such as NKT cells and nonclassical MHC class Ib–restricted CD8 cells appear to have TCR with higher avidity (48–50). Similarly, it is possible that thymocytes with higher TCR avidity could have been preferentially selected on MHC class II–positive thymocytes. The TCR signaling potency is known to be associated with Th cell differentiation (51–55). Therefore, the difference in TCR signaling potency could contribute to Th cytokine production by T-CD4 T cells. Previously, we demonstrated that the antigen repertoire of thymocytes does not totally overlap with that of TECs (19). Our current data also showed that the antigen presentation potential of thymic APCs seems to regulate the selection pathway and Th cell fate. Therefore, it appears that developing thymocytes receive different signal strength when they are selected on thymocytes, generating a distinct cellular phenotype of cells. This is consistent with the similar cytokine production potential observed in both T-CD4 T cells and NKT cells.

Despite the fact that T-CD4 cells can readily express Th2 cytokines in vivo, mice that can generate T-CD4 T

Figure 7. Allergen-induced airway inflammation is attenuated in CIITA Tg mice. Total BALF cells (A) and percentages of differential cell counts (B) in the BALF of WT and CIITA Tg mice 48 h after the last OVA aerosol treatment were determined. Each symbol in the graphs represents one mouse. Eos, eosinophils; Neu, neutrophils; LC, lymphocytes; MC, monocytes. (C) Reduced perivascular eosinophilic infiltration in CIITA Tg lung sections 2 d after the last exposure to OVA. Eosinophils are the red-staining cells in the H&E lung sections. Bars: (top) 100 μm; (bottom) 25 μm. (D) OVA-specific serum IgE levels. (E) Real-time RT-PCR of cytokine mRNA levels in the lung tissue of the OVA-challenged mice. The error bars represent the mean ± SD of six mice in each group. Horizontal lines in A and D represent median values. The Student’s two-tailed t test was used to calculate statistical significance. Data are pooled from two independent experiments. P < 0.05 was considered statistically significant.* P < 0.05; ** P < 0.01.
The phenotype of human Th cells suggests a distinct geometry compared to Th2 cells. This has been supported by the observation that T-CD4 T cells in CIITA Tg mice exhibit a phenotype similar to T-CD4 T cells in CIITA Tg mice. This suggests that the CIITA Tg mice may be a model for studying the role of CIITA in Th2 cell differentiation. However, this issue is complex and may depend on the experimental conditions. For example, in vitro assays may not accurately reflect the in vivo situation. Furthermore, the results obtained in CIITA Tg mice may not necessarily apply to human CD4 T cells.

Moreover, in vivo and in vitro experiments have shown that CD4 T cells can be selected on TECs and hematopoietic cells. This selection process can result in the generation of different CD4 T cell subsets with distinct effector functions. For instance, CD4 T cells can be selected on TECs and hematopoietic cells to produce both IL-4 and IFN-γ. Further investigations are warranted to elucidate the role of T-CD4 T cells in the modulation of immune diseases in humans.

**MATERIALS AND METHODS**

**Mice.** Mice carrying the human type III CIITA transgene (CIITA Tg), CIITA-deficient mice (CIITA−/−), CIITA Tg mice on the CIITA-deficient background (CIITA Tg/CIITA−/−) and on the MHC class II-deficient background (CIITA Tg/CIITA−/−), CIITA Tg mice on the MHC class II-transgenic mice (I-E Tg), CIITA Tg mice on the MHC class II-deficient background (I-E Tg/CIITA−/−) and on the MHC class II-deficient background (I-E Tg/CIITA−/−), and Stat6−/− mice were previously described (19, 29, 32, 34, 44). CD1d-deficient mice on the C57BL/6 background (38) were bred with CIITA Tg mice to generate CIITA Tg/CD1d−/− mice, and WT and CIITA Tg/CD1d−/− littermates were used as CD1d-positive controls. Stat6−/− mice were bred onto the H-2b background and carried the CD45.1 congenic marker. C57BL/6 (B6) mice and the MHC class II-deficient A/J (A) mice were purchased from the Jackson Laboratory and Taconic, respectively, and bred in the animal facility at the Indiana University School of Medicine (IUSM). All mice were housed under specific pathogen-free conditions and used at 6–12 wk of age. All animal experiments were performed under protocols approved by the IUSM Animal Care and Use Committee.

**In vivo anti-CD3 stimulation.** PBS or 10 μg anti-CD3 antibody in PBS was injected into WT or CIITA Tg mice through the tail vein. 2 h later, mice were killed and blood was collected by cardiac puncture. Serum cytokines were determined by ELISA.

**BM chimeras.** Recipient B6, A/J, or CIITA−/− mice were lethally irradiated (950 rad) and rested for 24 h before receiving BM cells. Total BM cells were prepared from the femurs and tibias of donor mice (2–3 mo of age) and depleted of mature T cells, B cells, and MHC class II-positive lymphocytes by using a cocktail of antibodies containing anti-CD4 (R172) and anti-CD8 (TIB105, TIB210), anti-CD19 (1D3), and anti-MHC class II (M5/114), followed by complement-mediated lysis. These cells were subsequently retransferred to T-depleted BM recipients. Each recipient mouse received 2.5 × 10^6 T-depleted BM cells in 500 μl of 1× PBS via tail vein injection. Reconstituted mice were analyzed 2–3 mo later.

**Flow cytometry.** All antibodies for flow cytometry were purchased from BD Biosciences, and cells were preincubated with the anti-FcγRI mAb 2.4G2 to block nonspecific antibody binding. The following FITC-, PE-, PerCP-, chromo-, allophycocyanin-, or biotin-conjugated antibodies were used: CD4 (L3T4), CD8 (33-6.7), CD45RB (16A), CD44 (IM7), NK1.1 (PK136), CD1d (1B1), CD45.1 (A20), CD45.2 (104), anti–IL-4 (11B1), and anti–IFN-γ (XMG1.2). Allophycocyanin-conjugated streptavidin was used to visualize staining by biotinylated primary antibodies. Events were acquired on a flow cytometer (FACSCalibur; Beckman Dickinson), and the data were analyzed using CellQuest software (BD Biosciences).

**T cell preparation and stimulation.** To purify CD4 and CD8 SP T cells, total thymocytes were depleted of double-positive cells by complement-mediated lysis of HA® cells. The remaining cells were subsequently sorted electronically for NK1.1+CD4+CD8− and NK1.1−CD4+CD8+ cells. Total peripheral CD4 cells were enriched from single-cell suspensions from spleen and lymph nodes (auxiliary, brachial, inguinal, and mesenteric) with anti-mouse CD4 microbeads (Miltenyi Biotec). To obtain naive CD4 T cells, enriched CD4 T cells were stained with anti-CD4, CD45RB, and CD44 and electronically sorted for CD4+CD45RB+CD44+ cells. In some experiments, CD4 T cells were enriched from splenocytes. To induce Th cell differentiation under neutral conditions (Th0), total peripheral, splenic CD4 T cells or 10^6 naive T cells/ml were stimulated with 5 μg/ml of plate-bound...
anti-CD3e (145-2C11), 1 μg/ml anti-CD28 (37.51), and 50 U IL-2 (Roche)
for 5–7 d. For Th1 cell differentiation, and additional 3.5 ng/ml IL-12 and
10 μg/ml anti-IL-4 (11B11) were added. Th2 cells cultures were supple-
mented with 10 ng/ml IL-4 and 10 μg/ml anti-IFN-γ (R4-6A2).

Cytokine assays. For the ELISA assays, differentiated cells were restim-
lulated overnight with 5 μg/ml of plate-bound anti-CD3 antibody at a cell
density of 1 × 10^6/ml. IL-4 and IFN-γ in the supernatants were quantifi-
cated by paired cytokine-specifi c antibodies (BD Biosciences). Recombinant cyto-
kines were used as standards. For IFN-γ, cells were stimulated with 50 ng/ml
g shootout (BD Biosciences) for IFN-γ, and stained with XMG1.2 for flow cytometry.

RT-PCR. Total RNA was extracted from sorted CD4 SP thymocytes lysed in
TRiZol reagent (Invitrogen), according to the manufacturer’s recommenda-
tions, and reverse transcribed using the SuperScript First-Strand cDNA Syn-
thetis System (Invitrogen). Quantitative real-time PCR was performed with
SYBR Green PCR Master Mix (Applied Biosystems). All PCR reactions were
done in triplicate, and the data were analyzed by the comparative threshold
cycle (ΔΔCt) method and normalized to GAPDH. The primer pairs used for
GAPDH were 5′-CCAGTGTGGTCTCCTGCAGCCT-3′ and 5′-ATAC-
CAGGAAATGACGGTGAAGT-3′, and for IL-4 were 5′-ACAG-
GAGAAGGACGACCCT-3′ and 5′-GAAGCTTACAGACGACGTCA-3′
(73). Message levels of IFN-γ, IL-4, IL-5, IL-13, and IL-17A in the lung tissue were
analyzed by TaqMan PCR (all reagents were obtained from Applied Bio-
systems). Cycle number of duplicate samples was normalized to expression of
β2-microglobulin. Results are relative to one of the WT mice.

ChIP analysis. ChIP analysis was performed according to the ChIP assay
protocol (Upstate Biotechnology). In brief, 2–3 × 10^6 sorted CD4 or CD8
SP thymocytes or sorted naive CD4 cells from WT and CIITA Tg mice were
fixed in 1% formaldehyde for 10 min at room temperature, washed, lysed, and
sonicated with three pulses to generate chromatin fragments of ~500-bp
in length. Antizetylated histone H3 antibody (Upstate Biotechnology) was
added (3 μl per immunoprecipitation) to the diluted lysates and incubated
overnight. No antibody group was used as a negative control. Protein A–
sepharose CL-4B beads (GE Healthcare) were added for 1 h. After washes,
the immunocomplexes were eluted, the cross-links were reversed, and DNA
was purifi ed by phenol/chloroform extraction and resexsposed in 50 μl TE
buffer. Semiquantitative PCR was done with twofold serial dilutions of
ChIP DNA samples. The primers used for IL-4 IE were 5′-GGGTGT-
GAATAAAGCCATATTG-3′ and 5′-CCCAAGGCTTTACATGAGC-3′ (40),
and for CD3ε were 5′-CATTTCCAATGGACGTGG-3′ and 5′-AACA-
CAGTGGCTGATGCC-3′ (39).

OVA-induced airway infl ammation. On days 0 and 7, mice were sensi-
tized i.p. with 20 μg OVA (grade V; Sigma-Aldrich) adsorbed onto 0.5 mg of
aluminum hydroxide gel (Sigma-Aldrich) in 0.5 ml PBS. Beginning on day
14, mice were challenged with aerosolized OVA from a 1% OVA/PBS solu-
tion for 20 min using a jet nebulizer for 7 consecutive days. 2 d after the last
aerosol challenge, mice were anesthetized with sodium pentobarbital. BALF
was collected from airways by three washes with 1 ml PBS. After BALF collec-
tion, slides were fi xed in 10% buff ered formalin for histological examination. The remaining
lung tissue was stored in RNAlater solution (Ambion) and homogenized in
TRiZol for RNA preparation. After cytospin of the BALF, slides were
stained with the Diff-Quick stain set (Baxter), and differential cell numbers
were determined by counting 200 cells per slide. OVA-specifi c IgE levels in
the supernatants were quantifi ed by ELISA, and the data were expressed as OD readings.
Fixed lung tissues were embedded in paraffin, cut into 5-μm-thick sections, and
stained with H&E for histological analysis of airway infl ammation.

Online supplemental material. Table S1 shows MHC class II, Ii, and H-2M expression in mice used in this study. Fig. S1 shows MHC class II expres-
sison on thymocytes and CD44 and CD45RB expression on splenic CD4 T
replies from WT, CIITA Tg , and CIITA Tg /CIITA Tg mice. Fig. S2 shows
the gate used to sort naive CD4 T cells (CD45RB–CD44+). Fig. S3 shows
IL-4 and IFN-γ production by Th1 and Th2 cells differentiated from total
WT, CIITA Tg , and CIITA Tg /CIITA Tg CD4 T cells. Fig. S4 shows the
generation of E- and T-CD4 T cells in BM chimeric mice. The FACS
plots represent profi les of CD4 versus CD8 in the thymus and LN. Fig. S5 shows
IL-4 production by TEC- and thymocyte-selected Stat6–/– thymo-
cytes and splenic CD4 T cells from chimeras that were reconstituted with
Stat6–/– and WT or CIITA Tg BM. Online supplemental material is available
at http://www.jem.org/cgi/content/full/jem.20070321/DC1.
