Abstract
We study the limit behaviour of solutions of
\[ \partial_t u - \Delta u + h(|x|)|u|^{p-1}u = 0 \quad \text{in } \mathbb{R}^N \times (0,T) \]
with initial data \( k\delta_0 \) when \( k \to \infty \), where \( h \) is a positive nondecreasing function and \( p > 1 \). If \( h(r) = r^\beta, \beta > N(p-1)-2 \), we prove that the limit function \( u_\infty \) is an explicit very singular solution, while such a solution does not exist if \( \beta \leq N(p-1)-2 \). If \( \liminf_{r \to 0} r^2 \ln(1/h(r)) > 0 \), \( u_\infty \) has a persistent singularity at \((0,t) (t \geq 0)\). If \( \int_0^T r \ln(1/h(r)) dr < \infty \), \( u_\infty \) has a pointwise singularity localized at \((0,0)\).

1991 Mathematics Subject Classification. 35K60.
Key words. Parabolic equations, Saint-Venant principle, very singular solutions, razor blade, Keller-Osserman estimates, asymptotic expansions.

1 Introduction
Consider
\[ \partial_t u - \Delta u + h(x)|u|^{p-1}u = 0 \quad \text{in } Q_T := \mathbb{R}^N \times (0,T), \]
with \( p > 1 \) and \( h \) is a nonnegative measurable function defined in \( \mathbb{R}^N \). It is well known that if
\[ \iint_{Q_T} h(x)E^p(x,t)dx\,dt < \infty, \]
where \( E(x,t) = (4\pi t)^{-N/2}e^{-|x|^2/4t} \) is the heat kernel, then, for any \( k > 0 \) there exists a unique solution \( u = u_k \) to (1.1) satisfying initial condition
\[ u(.,0) = k\delta_0 \]
in the sense of measures in $\mathbb{R}^N$. Furthermore the mapping $k \mapsto u_k$ is increasing. If it assumed that $h$ is positive essentially locally bounded from above and from below in $\mathbb{R}^N \setminus \{0\}$, then the set $\{u_k\}$ is also bounded in the $C^1_{\text{loc}}(\overline{Q}_T \setminus \{0 \times (0, \infty)\})$-topology. Thus there exist $u_\infty := \lim_{k \to \infty} u_k$ and $u_\infty$ is a solution of (1.1) in $Q_T \setminus \{0 \times (0, \infty)\}$. Furthermore $u_\infty$ is continuous in $\overline{Q}_T \setminus \{0 \times (0, \infty)\}$ and vanishes on $\mathbb{R}^N \setminus \{0\} \times \{0\}$. Only two situations can occur:

(i) Either $u_\infty(0, t) = \infty$ for every $t > 0$ and $u_\infty$ is a solution of (1.1) in $Q_T$. Such a solution which has a pointwise singularity at $(0, 0)$ is called a \textit{very singular solution} (abr. V.S.S.)

(ii) Or $u_\infty(0, t) = 0$ for every $t > 0$ and $u_\infty$ is a solution of (1.1) in $Q_T \setminus \{0 \times (0, \infty)\}$ only. Such a solution with a persistent singularity is called a \textit{razor blade} (abr. R. B.).

In the well-known article [4], Brezis, Peletier and Terman proved in 1985 that $u_\infty$ is a V.S.S., if $h(x) \equiv 1$. Furthermore they showed that $u_\infty(x, t) = t^{-1/(p-1)}f(x/\sqrt{t})$ for $(x, t) \in Q_T$ where $f$ is the unique positive (and radial) solution of the problem

\[
\begin{align*}
-\Delta f - \frac{1}{2} \eta \nabla f - \frac{1}{p-1} f + |f|^{p-1} f &= 0 & \text{in } \mathbb{R}^N \\
\lim_{|\eta| \to \infty} |\eta|^{2/(p-1)} f(\eta) &= 0.
\end{align*}
\]  

Their proof of existence and uniqueness relied on shooting method in ordinary differential equations (abr. O.D.E.). The already mentioned self-similar very singular solutions of the problem (1.4) was discovered independently in [6] too. Later on, a new proof of existence, has been given by Escobedo and Kavian [8] by a variational method in a weighted Sobolev space. More precisely they proved that the following functional

\[
v \mapsto J(v) = \frac{1}{2} \int_{\mathbb{R}^N} \left(|\nabla v|^2 - \frac{1}{p-1} v^2 + \frac{2}{p+1} |v|^{p+1}\right) K(\eta) d\eta
\]  

achieves a nontrivial minimum in $H^1_{K}(\mathbb{R}^N)$, where $K(\eta) = e^{\eta^2/4}$.

In this article we first study equation (1.1) when $h(x) = |x|^\beta$ ($\beta \in \mathbb{R}$). Looking for self-similar solutions under the form $u(x, t) = t^{-(2+\beta)/(p-1)}f(x/\sqrt{t})$, we are led to

\[
\begin{align*}
-\Delta f - \frac{1}{2} \eta \nabla f - \frac{2 + \beta}{2(p-1)} f + |\eta|^\beta |f|^{p-1} f &= 0 & \text{in } \mathbb{R}^N \\
f &\in H^1_{\text{loc}}(\mathbb{R}^N) \cap L^{p+1}_{\text{loc}}(\mathbb{R}^N; |\eta|^\beta d\eta) \cap C^2_0(\mathbb{R}^N \setminus \{0\}) \\
\lim_{|\eta| \to \infty} |\eta|^{(2+\beta)/(p-1)} f(\eta) &= 0,
\end{align*}
\]  

and the associated functional

\[
v \mapsto J(v) = \frac{1}{2} \int_{\mathbb{R}^N} \left(|\nabla v|^2 - \frac{2 + \beta}{2(p-1)} v^2 + \frac{2}{p+1} |\eta|^\beta |v|^{p+1}\right) K(\eta) d\eta.
\]  

We prove the following

\textbf{Theorem A} I- Assume $\beta \leq N(p-1) - 2$; then there exists no nonzero solution to (1.6).

II- Assume $\beta > N(p-1) - 2$; then there exists a unique positive solution $f^*$ to (1.6).

One of the key arguments in the study of isolated singularities of (1.1) is the following a priori estimate

\[
|u(x, t)| \leq \frac{c}{(t + |x|^2)^{(2+\beta)/(2(p-1))}} & \forall (x, t) \in Q_T
\]  

valid for any $p > 1$ and $\beta > -2$. The remarkable aspect of this proof is that it is based upon the auxiliary construction of the maximal solution of (1.1) under a self-similar form. Next we give two
proofs of II, one based upon scaling transformations and asymptotic analysis of O.D.E., combining
ideas from [4], [5] and [10], and the second based on variational methods, extending some ideas
from [8] and valid in a more general context. As a consequence we prove

Theorem B Assume \( \beta > N(p-1) - 2 \), then \( u_\infty(x,t) = t^{-(2+\beta)/(2(p-1))} f^*(x/\sqrt{t}) \).

It must be noticed that, if \( \beta \leq N(p-1) - 2 \), \( u_k \) does not exist, and more precisely, the isolated
singularities of solutions of (1.1) are removable.

Next we consider the case of more degenerate potentials \( h(x) \):

\[
\frac{h(x)}{|x|^\alpha} \to 0 \quad \text{as} \quad |x| \to 0 \quad \forall \alpha > 0. \quad (1.9)
\]

In the set of such potentials we find the borderline which separates the above mentioned two
possibilities (i) — (V.S.S.) and (ii) — (R.B). Remark that in the case of flat potentials like (1.9),
the corresponding solution \( u_\infty(x,t) \) does not have self-similar structure and we have to find some
alternative techniques for the study of the structure of \( u_\infty \). The main results of the paper are the
following two statements.

Theorem C (sufficient condition for V.S.S. solution) Assume that the function \( h \) is contin-
uous and positive in \( \mathbb{R}^N \setminus \{0\} \) and verifies the following flatness condition

\[
|x|^2 \ln \left( \frac{1}{h(x)} \right) \leq \omega(|x|) \iff h(x) \geq e^{-\omega(|x|)|x|^2} \quad \forall x \in \mathbb{R}^N, \quad (1.10)
\]

where the function \( \omega \geq 0 \) is nondecreasing, satisfies the following Dini-like condition

\[
\int_0^1 \frac{\omega(s)}{s} ds < \infty, \quad (1.11)
\]

and the additional technical condition

\[
s\omega'(s) \leq (2 - \alpha_0)\omega(s) \quad \text{near} \ 0, \quad (1.12)
\]

for some \( \alpha_0 \in (0,2) \). Then \( u_\infty(x,t) < \infty \) for any \( (x,t) \in Q_T \). Furthermore there exists positive
constants \( C_i \) (\( i = 1,2,3 \)), depending only on \( N, \alpha_0 \) and \( p \), such that

\[
\int_{\mathbb{R}^N} u_\infty^2(x,t) dx \leq C_1 t \exp \left[ C_2 \left( \Phi^{-1} (C_3 t) \right)^{-2} \right] \quad \forall t > 0, \quad (1.13)
\]

where \( \Phi^{-1} \) is the inverse function of

\[
\Phi(\tau) := \int_0^\tau \frac{\omega(s)}{s} ds.
\]

Notice that (1.11) - (1.12) is satisfied if \( h(x) \geq Ce^{-|x|^\theta - 2} \) for some \( \theta > 0 \).

Theorem D (sufficient condition for R.B. solution) Assume \( h \) is continuous and positive in \( \mathbb{R}^N \setminus \{0\} \) and satisfies

\[
\liminf_{x \to 0} |x|^2 \ln \left( \frac{1}{h(x)} \right) > 0 \iff \exists \omega_0 = \text{const} > 0 : h(x) \leq \exp \left( \frac{\omega_0}{|x|^2} \right). \quad (1.14)
\]

Then \( u_\infty(0,t) = \infty \) for any \( t > 0 \), and \( t \mapsto u_\infty(x,t) \) is increasing. If we denote \( U(x) = \lim_{t \to \infty} u_\infty(x,t) \), then \( U \) is the minimal large solution of

\[
-\Delta u + h(x)u^p = 0 \quad \text{in} \ \mathbb{R}^N \setminus \{0\}, \quad (1.15)
\]
i.e. the smallest solution of (1.15) which satisfies
\[ \int_{B_\epsilon} u(x) dx = \infty \quad \forall \epsilon > 0. \]  \tag{1.16}

Theorem C is proved by some new version of local energy method. A similar variant of this method was used in [1] for the study of extinction properties of solutions of nonstationary diffusion-absorption equations.

Theorem D is obtained by constructing local appropriate sub-solutions. The monotonicity and the limit property of \( u_\infty \) are characteristic of razor blades solutions [16].

A natural question which remains unsolved is to characterize \( u_\infty \) if the potential \( h(x) \) satisfies
\[ h(x) \approx \exp \left( -\frac{\omega(|x|)}{|x|^2} \right), \]
where \( \omega(s) \to 0 \) as \( s \to 0 \) and
\[ \int_0^1 \frac{\omega(s) ds}{s} = \infty. \]

This article is the natural continuation of [12], [14] where (1.1) is replaced by
\[ \partial_t u - \Delta u + h(t) |u|^{p-1}u = 0 \quad \text{in} \ Q_T. \]  \tag{1.17}

In equation (1.17), the function \( h \in C([0,T]) \) is positive in \((0,T)\) and vanishes only at \( t = 0 \). In the particular case \( h(t) = t^\beta \) \((\beta > 0)\), \( u_k \) exists if and only if \( 1 < p < 1 + 2(1 + \beta)/N \), and \( u_\infty \) is an explicit very singular solution. If \( h(t) \geq e^{-\omega(t)/t} \), then \( u_\infty \) has a pointwise singularity at \((0,0)\). If the degeneracy of \( h \) is stronger, namely
\[ \liminf_{t \to 0} t \ln h(t) > -\infty, \]
it is proved that the singularity of \( u_k \) propagates along the axis \( t = 0 \); at end, \( u_\infty \) is nothing else than the (explicit) maximal solution \( \Psi(t) \) of the O.D.E.
\[ \Psi' + h(t) \Psi^p = 0 \quad \text{in} \ (0, \infty). \]  \tag{1.18}

A very general and probably difficult open problem generalizing (1.1) and (1.17) is to study the propagation phenomenon of singularities starting from \((0,0)\) when (1.1) is replaced by
\[ \partial_t u - \Delta u + h(x,t) |u|^{p-1}u = 0 \quad \text{in} \ Q_T, \]  \tag{1.19}
where \( h \in C(\overline{Q_T}) \) is nonnegative and vanishes only on a curve \( \Gamma \subset \overline{Q_T} \) starting from \((0,0)\). It is expected that two types of phenomena should occur:
(i) either \( u_\infty \) has a pointwise singularity at \((0,0)\),
(ii) or \( u_\infty \) is singular along \( \Gamma \) or a connected part of \( \Gamma \) containing \((0,0)\).

It is natural to conjecture that the order of degeneracy should be measured in terms of the parabolic distance to \( \Gamma \) and of the slope of \( \Gamma \) in the space \( \mathbb{R}^N \times \mathbb{R} \). This could serve as a starting model for nonlinear heat propagation in inhomogeneous fissured media.

Our paper is organized as follows: 1 Introduction - 2 The power case - 3 Pointwise singularities - 4 Existence of razor blades.

Acknowledgements The authors have been supported by INTAS grant Ref. No : 05-1000008-7921.
2 The power case

In this section we assume that \( h(x) = |x|^\beta \) with \( \beta \in \mathbb{R} \), and the equation under consideration is the following

\[
\partial_t u - \Delta u + |x|^{\beta} |u|^{p-1} u = 0 \quad \text{in } Q_T := \mathbb{R}^N \times (0, T),
\]

with \( p > 1 \). By a solution we mean a function \( u \in C^{2,1}(Q_T) \). Let \( E(x, t) = (4\pi t)^{-N/2} e^{-|x|^2/4t} \) be the heat kernel in \( Q_T \) and \( E[\phi] \) the heat potential of a function (or measure) \( \phi \) defined by

\[
E[\phi](x, t) = \frac{1}{(4\pi t)^{N/2}} \int_{\mathbb{R}^N} e^{-|x-y|^2/4t} \phi(y) \, dy.
\]

If there holds

\[
\int_{Q_T} E^p(x, t)|x|^\beta \, dx \, dt < \infty,
\]

it is easy to prove (see [12, Prop 1.2], and [18, Th 6.12]), that for any function \( u = u_k \in L^1(B_R \times (0, T)) \cap L^p(B_R \times (0, T); |x|^\beta dx) \) such that

\[
\int_{Q_T} (-u \partial_t \zeta - u \Delta \zeta + |x|^{\beta} |u|^{p-1} u \zeta) \, dx \, dt = k \zeta(0, 0),
\]

for any \( \zeta \in C^2_0(\mathbb{R}^N \times [0, T)) \). By the maximum principle \( k \mapsto u_k \) is increasing. Next, it is straightforward that (2.3) is fulfilled as soon as

\[
\beta > \max\{N(p - 1) - 2; -N\}.
\]

2.1 The a priori estimate and the maximal solution

In order to prove an a priori estimate, we introduce the auxiliary \( N \) dimensional equation in the variable \( \eta = x/\sqrt{t} \)

\[
-\Delta f - \frac{1}{2} \eta \nabla f - \gamma f + |\eta|^{\beta} |f|^{p-1} f = 0,
\]

where \( \gamma = (2 + \beta)/2(p - 1) \).

**Proposition 2.1** Let \( a > 0 \) and \( \beta \in \mathbb{R} \); then there exists a unique nonnegative function \( F_a \in H^1_{loc}(B_a) \cap L^p_{loc}(B_a; |\eta|^\beta dy) \) solution of (2.6) and satisfying

\[
\lim_{|\eta| \to a} F_a(\eta) = \infty.
\]

Furthermore \( a \mapsto F_a \) is decreasing.

**Proof.** Set \( K(\eta) = e^{\eta^2/4} \). Then (2.6) becomes

\[
-K^{-1} \text{div}(K \nabla f) - \gamma f + |\eta|^{\beta} |f|^{p-1} f = 0.
\]

**Step 1- Boundary behaviour.** First we claim that

\[
\lim_{|\eta| \to a} (a - |\eta|)^{2/(p-1)} F_a(\eta) = \left( \frac{2(p+1)}{a^{p+1}(p-1)^2} \right)^{1/(p-1)}.
\]

Actually, if \( 0 < b < |\eta| < a \), \( u \) satisfies

\[
-K^{-1} \text{div}(K \nabla F_a) - \gamma F_a + CF_a^p \leq 0
\]
with \( C = \min\{a^\beta, b^\beta\} \). We perform a standard variant of the two-sides estimate method used in \([17]\) : we set \( \Gamma := B_p \setminus B_b \) with \( b < \rho < a, \alpha = (\rho - b)/2 \) and denote by \( z \) the solution of

\[
\begin{aligned}
\left\{ \begin{array}{l}
z'' - Cz^p = 0 \quad \text{in } (-\alpha, \alpha) \\
z(-\alpha) = z(\alpha) = \infty.
\end{array} \right.
\end{aligned}
\tag{2.10}
\]

Then \( z \) is an even function and is computed by the formula

\[
\int_{z(t)}^{\infty} \frac{ds}{\sqrt{s^{p+1} - z(0)^{p+1}}} = \sqrt{\frac{2C}{p+1}} (\alpha - t) \quad \forall t \in [0, \alpha).
\tag{2.11}
\]

Notice also that \( \lim_{\alpha \to 0} z(t) = \infty \), uniformly on \((-\alpha, \alpha)\) and

\[
\lim_{t \to \alpha} (t - \alpha)^{2/(p-1)} z(t) = \left( \frac{2(p+1)}{Cp(p-1)^2} \right)^{1/(p-1)}.
\tag{2.12}
\]

We set \( Z(\eta) = z(|\eta| - (\rho + b)/2) \) and we look for a super-solution in \( \Gamma \) under the form \( w = MZ(\eta) \) \((M > 1)\). Then

\[
-K^{-1} \div (K\nabla w) - \gamma w + Cw^p = M \left( (M^{p-1} - 1)Cz^p - \left( \frac{N - 1}{|\eta|} + \frac{|\eta|}{2} \right) z' - \gamma z \right).
\]

Since

\[
z'(t) = \sqrt{\frac{2C}{p+1}} z^{p+1}(t) - z(0)^{p+1} < C^* z^{(p+1)/2}(t), \quad \text{with } C^* = \sqrt{\frac{2C}{p+1}},
\]

we derive

\[
-K^{-1} \div (K\nabla w) - \gamma w + Cw^p \geq M \left( (M^{p-1} - 1)Cz^p - \left( \frac{N - 1}{b} + \frac{a}{2} \right) C^* z^{(p+1)/2} - \gamma z \right)
\tag{2.13}
\]

on \( \{ \eta : (\rho - b)/2 |\eta| < \rho \} \); and the same inequality holds true on \( \{ \eta : \rho < |\eta| < (\rho - b)/2 \} \), up to interverting \( a \) and \( b \). For any \( M > 1 \), we can choose \( b > 0 \) such that for any \( b < \rho < a \), the right-hand side of (2.13) is positive and maximum principle applies in \( B_p \setminus B_b \). Thus \( MZ \geq F_a \) in \( \Gamma \). Furthermore, the previous comparison still holds if we take \( \rho = a \), which implies \( \alpha = (a-b)/2 \). Therefore, using the explicit value of \( C \)

\[
\limsup_{|\eta| \to a} (a - |\eta|)^{2/(p-1)} F_a(\eta) \leq M \left( \frac{2(p+1)}{\min\{a^\beta, b^\beta\}(p-1)^2} \right)^{1/(p-1)}.
\tag{2.14}
\]

Because \( M > 1 \) and \( 0 < b < a \) are arbitrary, we derive

\[
\limsup_{|\eta| \to a} (a - |\eta|)^{2/(p-1)} F_a(\eta) \leq \left( \frac{2(p+1)}{a^\beta(p-1)^2} \right)^{1/(p-1)}.
\tag{2.15}
\]

For the estimate from below we notice that \( u \) satisfies

\[
-K^{-1} \div (K\nabla F_a) - \gamma F_a + \tilde{C} F_a^p \geq 0
\]

in \( \{ \eta : b < |\eta| < a \} \), with \( \tilde{C} = \max\{a^\beta, b^\beta\} \). Taking now \( \alpha = a - b \), we denote by \( \tilde{z} \) the positive solution of

\[
\begin{aligned}
\left\{ \begin{array}{l}
z'' + \gamma \tilde{z} - \tilde{C} \tilde{z}^p = 0 \quad \text{in } (0, \alpha) \\
\tilde{z}(0) = 0 \\
\tilde{z}(\alpha) = \infty.
\end{array} \right.
\end{aligned}
\tag{2.16}
\]
Then \( \tilde{z} \) is computed by the formula

\[
\int_0^{\infty} \frac{ds}{\sqrt{\tilde{z}^2(0) - \gamma s^2 + 2\tilde{C} s^{p+1}/(p+1)}} = \alpha - t \quad \forall t \in [0, \alpha),
\]

and formula (2.12) is valid provided \( C \) be replaced by \( \tilde{C} \). We fix \( A \in \partial B_a \) with coordinates \((a, 0, \ldots, 0)\), and look for a subsolution under the form \( \tilde{w}(\eta) = M \tilde{z}(\eta - b) \) with \( 0 < M < 1 \). Then

\[
-K^{-1} \text{div}(K \nabla \tilde{w}) - \gamma \tilde{w} + \tilde{C} \tilde{w}^p = \tilde{M} \left( (\tilde{M}^{p-1} - 1) \tilde{z}^p - \frac{\eta}{2} \tilde{w}' \right) \leq 0,
\]

since \( \tilde{w}' \geq 0 \). Applying again the maximum principle, we derive \( \tilde{w}(\eta) \leq F_0 \) in \( B_a \cap \{ \eta : b < \eta_1 < a \} \). But clearly the direction \( \eta_1 \) is arbitrary and can be replaced by any radial direction. Thus

\[
\liminf_{|\eta| \to a} (a - |\eta|)^{2/(p-1)} F_a(\eta) \geq \tilde{M} \left( \frac{2(p+1)}{\max\{a^{p^2}, b^{p^2}\}(p-1)^2} \right)^{1/(p-1)}. \tag{2.18}
\]

In turn, (2.18) implies

\[
\liminf_{|\eta| \to a} (a - |\eta|)^{2/(p-1)} F_a(\eta) \geq \left( \frac{2(p+1)}{a^{p^2}(p-1)^2} \right)^{1/(p-1)}, \tag{2.19}
\]

and (2.9) follows from (2.15) and (2.19).

**Step 2 - Uniqueness.** If \( F' \) is another nonnegative solution of (2.6) satisfying the same boundary blow-up conditions, then for any \( \epsilon > 0 \), \( F'_\epsilon = (1 + \epsilon) F' \) is a super solution. Thus, for \( \delta > 0 \),

\[
\int \int_{B_a} \left( \frac{\text{div}(K \nabla F_a)}{F_a + \delta} + \frac{\text{div}(K \nabla F'_\epsilon)}{F'_\epsilon + \delta} + |\eta|^2 \left( \frac{F_a^p}{F_a + \delta} - \frac{F'_\epsilon^p}{F'_\epsilon + \delta} \right) K \right) ((F_a + \delta)^2 - (F'_\epsilon + \delta)^2)_+ \ d\eta \\
\leq \gamma \int \int_{B_a} \left( \frac{F_a}{F_a + \delta} - \frac{F'_\epsilon}{F'_\epsilon + \delta} \right) ((F_a + \delta)^2 - (F'_\epsilon + \delta)^2)_+ K d\eta.
\]

By monotonicity

\[
\left( \frac{F_a^p}{F_a + \delta} - \frac{F'_\epsilon^p}{F'_\epsilon + \delta} \right) ((F_a + \delta)^2 - (F'_\epsilon + \delta)^2)_+ \geq 0,
\]

and

\[
0 \leq \left( \frac{F_a}{F_a + \delta} - \frac{F'_\epsilon}{F'_\epsilon + \delta} \right) ((F_a + \delta)^2 - (F'_\epsilon + \delta)^2)_+ \leq ((F_a + \delta)^2 - (F'_\epsilon + \delta)^2)_+.
\]

By Lebesgue’s theorem, since (2.9) implies that \((F_a + \delta)^2 - (F'_\epsilon + \delta)^2)_+\) has compact support in \( B_a \),

\[
\lim_{\delta \to 0} \int \int_{B_a} \left( \frac{F_a}{F_a + \delta} - \frac{F'_\epsilon}{F'_\epsilon + \delta} \right) ((F_a + \delta)^2 - (F'_\epsilon + \delta)^2)_+ K d\eta = 0.
\]

Using Green formula, we obtain

\[
\int \int_{F_{\epsilon} \geq F'_\epsilon} \left( \nabla F_a - \frac{F_a + \delta}{F'_\epsilon + \delta} \nabla F'_\epsilon \right)^2 + \left| \nabla F'_\epsilon - \frac{F'_\epsilon + \delta}{F_a + \delta} \nabla F_a \right|^2 K d\eta \geq 0.
\]
Letting $\delta \to 0$, we derive, by Fatou’s theorem,

$$
\int \int_{F_a \geq F_0} (F^{p-1}_a - F^{p-1}_r) (F^2_a - F^2_r) K d\eta \leq 0.
$$

Thus $F_a \leq F_r$. Since $\epsilon$ is arbitrary, $F_a \leq F_r$. The reverse inequality is the same. The monotonicity of $a \mapsto F_a$ is proved in a similar way, by the previous form of maximum principle.

**Step 3: Existence with finite boundary value.** We shall first prove the existence of a positive solution $w_k$ of (2.20) with boundary value equal to $k > 0$ for small value of $a$, and we shall let $k \to \infty$ in order to obtain one solution satisfying (2.7). We denote by $J_a$ the functional defined over $H^1_0(B_a) \cap L^{p+1}(B_a; |\eta|^\beta d\eta)$ by

$$
J_a(w) = \frac{1}{2} \int_{B_a} \left( |\nabla w|^2 - \gamma w^2 + \frac{1}{p+1} |\eta|^\beta |w|^{p+1} \right) K(\eta) d\eta.
$$

Let $k > 0$ and $\kappa \in C^1(\overline{B}_a)$ with $0 \leq \kappa(\eta) \leq k$, supp($\kappa$) $\subset \overline{B}_a \setminus B_{a/2}$. If $v \in H^1_0(B_a) \cap L^{p+1}(B_a; |\eta|^\beta d\eta)$ and $w := v + \kappa$, then

$$
J_a(w) = J_a(v + \kappa) \geq J_a(v) + J_a(\kappa) + \int_{B_a} (\nabla v \cdot \nabla \kappa - \gamma v \kappa - |\eta|^\beta |v| \kappa) K(\eta) d\eta.
$$

Since $\gamma \leq \lambda_a$, it follows from Cauchy-Schwarz and Hölder-Young inequalities that

$$
J_a(w) \geq (1 - \epsilon^2) J_a(v) - \frac{p^p}{\epsilon^{2p}} J_a(\kappa)
$$

for $0 < \epsilon < 1$. Because $\lim_{a \to 0} \lambda_a = \infty$, there exists $a_0 \in (0, \infty]$ such that, for any $0 < a < a_0$, $J_a(v)$ is bounded from below on $H^1_0(B_a) \cap L^{p+1}(B_a; |\eta|^\beta d\eta)$. Thus there exists a minimizer $w_k$ such that $w_k = v + \kappa$ with $v$ in the above space; $w_k$ is a solution of (2.6) and $w_k|_{\partial B_a} = k$. Furthermore $w_k$ is positive. Notice that if $\gamma \leq 0$, $a_0 = \infty$, in which case there exists a solution $w_0$ for any $k > 0$ and any $a > 0$. The uniqueness of $w_k > 0$ is, a consequence of the monotonicity of the mapping $k \mapsto w_k$ that we prove by a similar argument as in Step 2: if $k < k'$, there holds

$$
\int \int_{w_k > w_{k'}} \left( w_k^{p-1} - w_{k'}^{p-1} \right) (w_k^2 - w_{k'}^2) |\eta|^\beta K d\eta \leq 0,
$$

which implies $w_k < w_{k'}$. Uniqueness and radiality follows immediately, thus $w_k$ solves the differential equation

$$
\begin{cases}
-w'' - \left( \frac{N-1}{r} + \frac{r}{2} \right) w' - \gamma w + r^3 w^p = 0 & \text{on } (0,a) \\
w(a) = k & \text{and } w \in H^1_{rad}(B_a) \cap L^{p+1}_{rad}(B_a; |\eta|^\beta d\eta).
\end{cases}
$$

(2.20)

Next we shall assume $\gamma > 0$, equivalently $\beta > -2$. If $w_k$ is a positive solution of (2.20) and $\lambda > 1$ (resp. $\lambda < 1$) $\lambda w_k$ is a super-solution (resp. a sub-solution) larger (resp. smaller) than $w_k$. Note that $\beta > -2$ implies $w_k(0) > 0$ while $\beta < 1$ implies also $w_k'(0) = 0$. Thus, by [13], there exists a solution $w_{\lambda k}$ with boundary data $\lambda k$, and this solution is positive because $w_k \leq w_{\lambda k} \leq \lambda w_k$ (resp. $\lambda w_k \leq w_{\lambda k} \leq w_k$). Consequently, the set $A$ of the positive $\tilde{a}$ such that there exists a positive solution of (2.20) on $(0,a)$ for any $a < \tilde{a}$ is not empty and independent of $k$. Furthermore, if for some $\tilde{a} > 0$ and some $k_0 > 0$, there exists some positive $w_{k_0}$ solution of (2.20) on $0, \tilde{a}$), then for any $0 < a < \tilde{a}$ and any $k > 0$, there exists a positive solution $w_k$ of (2.20). Since $r \mapsto \max\{k, (\gamma + a^{-\beta})^{1/(p-1)} \}$ is a super-solution, there holds

$$
w_k(r) \leq \max\{k, (\gamma + a^{-\beta})^{1/(p-1)} \} \quad \forall r \in [0,a].
$$

(2.21)
Let us assume that \( a^* = \sup A < \infty \). Because of (2.21) and local regularity of solutions of elliptic equations, for any \( \epsilon, \epsilon' > 0 \), \( w_k'(a) \) is bounded uniformly with respect to \( \epsilon \leq a < a^* - \epsilon' \). But since (2.20) implies

\[
a^{N-1}e^{\alpha z^2/4}w_k'(a) = e^{\alpha z^2/4}w_k'(\epsilon) + \int_{\epsilon}^{a}(\epsilon^\beta w_k^p - \gamma w_k) \frac{e^{\alpha z^2/4}}{\epsilon^{1/2}} \, dr,
\]

\( w_k'(a) \) is actually uniformly bounded on \( [\epsilon, a^*] \). It follows from the local existence and uniqueness theorem that there exists \( \delta > 0 \), independent of \( a < a^* \) such that there exists a unique solution \( z \) defined on \( [a, a + \delta] \) to

\[
\begin{cases}
-z'' = \left( \frac{N-1}{r} + \frac{r}{2} \right) z' - \gamma z + r^\beta z^p = 0 & \text{on } (0, a) \\
z(a) = k, \ z'(a) = w_k'(a),
\end{cases}
\]

and \( \delta \) and \( k > 0 \) can be chosen such that \( z > 0 \) in \( [a, a + \delta] \). This leads to the existence of a positive solution to (2.20) on \( [0, a + \delta] \). If \( a^* - a < \delta \), which contradicts the maximality of \( a^* \). Therefore \( a^* = \infty \).

**Step 4 - End of the proof.** We have already seen that \( k \mapsto w_k \) is increasing. By Step 1, we know that, for any \( a > 0 \), and some \( b < a \), there holds

\[
w_k(|\eta|) \leq C(a - |\eta|)^{-1/(p-1)} \text{ on } B_a \setminus B_b.
\]

In particular

\[
w_k(b) \leq C^* = C^*(a, b, p, N)
\]

Next

\[
w_k(r) \leq \max\{C^*, (\gamma + b^{-\beta})^{1/(p-1)}\} \quad \forall r \in [0, b].
\]

Combining (2.23) and (2.24) implies that \( w_k \) is locally uniformly bounded on \( [0, a] \). Since \( k \mapsto w_k \) is increasing, the existence of \( F_a := w_\infty = \lim_{k \to \infty} w_k \) follows. The fact that \( a \mapsto F_a \) decreases is a consequence of the fact that \( F_a \) is finite on \( \partial B_a \) for any \( a < a' \).

**Remark.** In the sequel we set \( F_\infty = \lim_{a \to \infty} F_a \). Then \( F_\infty \) is a nondecreasing, nonnegative solution of (2.6). Using asymptotic analysis, it is easy to prove that there holds:

(i) if \( \beta \neq 0 \)

\[
F_\infty(\eta) = \left( \frac{1}{p-1} \right)^{1/(p-1)} |\eta|^{-\beta/p-1}(1 + o(1)) \quad \text{as } |\eta| \to \infty;
\]

(ii) if \( \beta = 0 \)

\[
F_\infty(\eta) \equiv \left( \frac{1}{p-1} \right)^{1/(p-1)}
\]

Furthermore, if \( \beta > -2 \), it follows by the strict maximum principle that \( F_a(0) = \min\{F_a(\eta) : |\eta| < a\} > 0 \). This observation plays a fundamental role for obtaining estimate from above.

**Proposition 2.2** Assume \( p > 1 \) and \( \beta > -2 \). Then any solution \( u \) of (2.1) in \( QT \) which verifies

\[
\lim_{t \to 0} u(x, t) = 0 \quad \forall x \neq 0,
\]

satisfies

\[
|u(x, t)| \leq \min \left\{ c^* |x|^{-(2+\beta)/(p-1)} ; t^{-(2+\beta)/2(p-1)} F_\infty(x/\sqrt{7}) \right\} \quad \forall (x, t) \in QT \setminus \{0\},
\]

where \( c^* = c^*(N, p, \beta) \).
Proposition 2.3 Assume \( u \) satisfies the classical condition (2.27), \( u \) is a solution of \( (2.1) \) in \( \mathbb{R}^N \setminus \{0\} \). Then \( u \) satisfies

\[
|u(x,t)| \leq u_M(x,t) := t^{-(2+\beta)/2(p-1)} F_\infty(x/\sqrt{t}) \quad \forall (x,t) \in Q_T \setminus \{0\}.
\] (2.29)

As a variant of (2.28), we have the following Keller-Osserman type parabolic estimate which extends the classical one due to Brezis and Friedman in the case \( \beta = 0 \) (see [3]).

Proposition 2.4 Under the assumptions of Proposition 2.2 there holds

\[
|u(x,t)| \leq \frac{\tilde{c}}{(|x|^2 + t)^{(2+\beta)/2(p-1)}} \quad \forall (x,t) \in Q_T \setminus \{0\},
\] (2.30)

with \( \tilde{c} = \tilde{c}(N,p,\beta) \).

Proof. Assume \( |x|^2 \leq t \), then

\[
\frac{1}{(|x|^2 + t)^{(2+\beta)/2(p-1)}} \geq \frac{2^{-(2+\beta)/2(p-1)} t^{-(2+\beta)/2(p-1)}}{\min \{ F_\infty(\eta) : |\eta| \leq 1 \}} t^{-(2+\beta)/2(p-1)} F_\infty(x/\sqrt{t}).
\] (2.31)

Assume \( |x|^2 \geq t \), then

\[
\frac{1}{(|x|^2 + t)^{(2+\beta)/2(p-1)}} \geq 2^{-(2+\beta)/(p-1)} |x|^{-(2+\beta)/(p-1)}.
\] (2.32)

Combining (2.31) and (2.32) gives (2.30). \( \square \)
2.2 Isolated singularities and the very singular solution

**Theorem 2.5** Assume $p > 1$ and $-2 < \beta \leq N(p-1) - 2$. Then any solution $u$ to (2.1) which satisfies (2.27) is identically 0.

**Proof.** If $-(2+\beta)/(p-1) + N - 1 > -1$, equivalently $\beta < N(p-1) - 2$, the function $x \mapsto |x|^{-2(2+\beta)/(p-1)}$ is locally integrable in $\mathbb{R}^N$, thus $u(x,t) \to 0$ in $L^1_{loc}(\mathbb{R}^N)$ as $t \to 0$. For $\epsilon > 0$ there exists $R = R(\epsilon)$ such that $u(x,t) \leq \epsilon$ for any $|x| \geq R$ and $t > 0$. Thus

$$u(x,t+\tau) \leq \epsilon + \mathbb{E}[u X_{\eta,R} u(\cdot,\tau)](x,t) \quad \forall t > 0, \tau > 0 \text{ and } x \in \mathbb{R}^N,$$

(2.33)

where $\mathbb{E}[\phi]$ denotes the heat potential of the measure $\phi$ (see (2.2)). Letting successively $\tau \to 0$ and $\epsilon \to 0$, yields to $u \leq 0$. In the same way $u \geq 0$. In the case $\beta = N(p-1) - 2$ estimate (2.30) reads

$$|u(x,t)| \leq \frac{\tilde{c}}{|x|^2 + t^{N/2}}.$$

From this estimate, the proof of [3, Th 2, Steps 5, 6] applies and we recall briefly the steps

(i) By choosing positive test functions $\phi_n$ which vanish in $V_n = \{(x,t) : |x|^2 + t \leq n^{-1}\}$ and are constant on $\mathcal{V}_n = \{(x,t) : |x|^2 + t \geq 2n^{-1}\}$, we first prove that, for any $p > 0$,

$$\int \int_{B_n \times (0,T)} (|u(x,t)| + |x|^p |u|^p) \, dx \, dt < \infty.$$  

(2.34)

Thus, using the same test function, we derive that the identity

$$\int \int_{Q_T} (-u \partial_k \zeta - u \Delta \zeta + |x|^p |u|^{p-1} u \zeta) \, dx \, dt = 0,$$

(2.35)

holds for any $\zeta \in C_{0,1}^0(\mathbb{R}^N \times [0,T))$. The uniqueness yields to $u = 0$. \hfill $\Box$

**Proof of Theorem A- case I.** In the case $-2 < \beta \leq N(p-1) - 2$, the result is a consequence of Theorem 2.5. Next we assume $\beta \leq -2$. If $f$ is a solution of (1.6), it satisfies

$$f(\eta) = o(|\eta|^{-(2+\beta)/(p-1)}) \quad \text{as } |\eta| \to \infty.$$

If $\beta = -2$, the equation becomes

$$-\Delta f - \frac{1}{2} \eta \nabla f + |\eta|^{-2} |f|^{p-1} f = 0,$$

and $f(\eta) \to 0$ at infinity. Since any positive constant is a supersolution, $f \leq 0$. Similarly $f \geq 0$.

If $\beta < -2$, for $\epsilon > 0$ the function $\eta \mapsto \epsilon |\eta|^{-(2+\beta)/(p-1)} = \psi(\eta)$ belongs to $W_{loc}^{1,1}(\mathbb{R}^N)$ since $\beta < -2$ and satisfies

$$-\Delta \psi - \frac{1}{2} \eta \nabla \psi - \frac{2 + \beta}{2(p-1)} \psi + |\eta|^{\beta} |\psi|^{p-1} \psi = \epsilon r^{-(2+\beta)/(p-1)-2} \left( \frac{2 + \beta}{p-1} \right) \left( \frac{2 + \beta}{p-1} + 2 - N \right) + \epsilon^{p-1}.$$

Therefore, either if $N \geq 2$ or $N = 1$ and $\beta \leq -(p+1)$, $\psi$ is a super-solution of (1.6) for any $\epsilon > 0$. The conclusion follows as above.

Finally we treat the case $N = 1$ and $-(p+1) < \beta < -2$ where there exists a particular solution of

$$f'' + \frac{\alpha}{2} f' + \frac{2 + \beta}{2(p-1)} f - \alpha |f|^{p-1} f = 0 \quad \text{on } \mathbb{R}_+,$$
under the form \( f_1(r) = A_β r^{-(2+β)/(p-1)} \). Furthermore, if \( f ≥ 0 \) (which can be always assumed by the maximum principle), it is a subsolution of the linear equation

\[
\phi'' + \frac{r}{2} \phi' + \frac{2 + \beta}{2(p - 1)} \phi = 0
\]

Noticing that this equation has a solution \( \phi_1 \) which has the same behaviour at infinity than the explicit solution of (1.4), namely

\[
\phi_1(r) = cr^{-(2 + \beta)/(p - 1)}(1 + o(1)),
\]

by standard methods (see e.g. [10, Prop A1]), the second solution \( \phi_2 \) behaves in the following way

\[
\phi_2(r) = cr^{(2 + \beta)/(p - 1) - 1}e^{-r^2/4}(1 + o(1)) \quad \text{as} \quad r → ∞.
\]

Consequently, by the maximum principle, any solution \( f \) of (1.4) on \( \mathbb{R} \) such that \( f(r) = o(\phi_1(r)) \) at infinity, verifies

\[
|f(r)| ≤ C|r|^{(2 + \beta)/(p - 1) - 1}e^{-r^2/4} \quad \text{for} \quad |r| ≥ 1. \tag{2.36}
\]

Using the equation, we obtain that

\[
f'(r) = e^{r^2/4} \int_r^∞ \left( s^{β}|f(s)|^{p-1}f(s) - \frac{2 + \beta}{p - 1} f(s) \right) ds,
\]

thus

\[
|f'(r)| ≤ C_β |r|^{(2 + \beta)/(p - 1) - 2}e^{-r^2/4} \quad \text{for} \quad |r| ≥ 1. \tag{2.37}
\]

Since \( f ∈ H^1_{loc}(\mathbb{R}) \), we derive that for any \( n ∈ \mathbb{N}_+ \),

\[
\int_{-n}^{n} \left( f'^2 - \frac{2 + \beta}{p - 1} f^2 \right) e^{r^2/4} dr ≤ e^{n^2/4} (f(n)f'(n) - f(-n)f'(-n)).
\]

Because of (2.36) and (2.37), this last term tends to 0 as \( n → ∞ \). Therefore

\[
\int_{-∞}^{∞} \left( f'^2 - \frac{2 + \beta}{p - 1} f^2 \right) e^{r^2/4} dr = 0 \Rightarrow f = 0,
\]

which end the proof. \( □ \)

Remark. The method of proof used in the case \( N = 1 \) and \(-p - 1 < β < -2\) is actually valid in any dimension, for any \( β ≤ -2 \). But it relies strongly on the fact that \( f ∈ H^1_{loc}(\mathbb{R}^N) \), while the other methods use only \( f ∈ W^{1,1}_{loc}(\mathbb{R}^N) \).

Proposition 2.6 Assume \( β > \max\{N(p - 1) - 2; -N\} \). Then for any \( k > 0 \) there exists a unique solution \( u_k \) of (2.1) with initial data \( kδ_0 \). Furthermore \( k → u_k \) is increasing and \( u_∞ := \lim_{k → ∞} u_k \) satisfies \( u_∞(x, t) = t^{-(2 + β)/(2(p - 1))}f_∞(x/\sqrt{t}) \), where \( f_∞ \) is positive, radially symmetric and satisfies

\[
\begin{cases}
-Δf_∞ - \frac{1}{2}\eta \nabla f_∞ - γ f_∞ + |\eta|^β f^p_∞ = 0 & \text{in} \ \mathbb{R}^N \\
\lim_{|\eta| → ∞} |\eta|^{(2 + β)/(p - 1)} f_∞(\eta) = 0.
\end{cases} \tag{2.38}
\]

Proof. The existence of \( u_k \) and the monotonicity of \( k → u_k \) has already been seen. By the uniform continuity of the \( u_k \) in any compact subset of \( Q_T \setminus \{(0, 0)\} \), the function \( u_∞ \) satisfies

\[
\lim_{t → 0} u_∞(x, t) = 0 \quad \forall x \neq 0. \tag{2.39}
\]
For $\ell > 0$ and $u$ is defined in $Q_\infty$, we set
$$T_\ell[u](x, t) := e^{(2+\beta)/2(p-1)}u(\sqrt{\ell}x, \ell t).$$  
(2.40)

If $u$ satisfies equation (2.1) in $Q_\infty$, $T_\ell[u]$ satisfies it too. Because of uniqueness
$$T_\ell[u_k] = u_k(\ell(2+\beta)/(2(p-1))-N/2)_k.$$  
(2.41)

Using the continuity of $u \mapsto T_\ell[u]$ and the definition of $u_\infty$, we can let $k \to \infty$ in (2.41) and derive (by taking $\ell t = 1$ and replacing $t$ by $t$),
$$T_\ell[u_\infty] = u_\infty \Rightarrow u_\infty(x, t) = t^{-(2+\beta)/2(p-1)}u_\infty(x/\sqrt{\ell}, 1).$$  
(2.42)

Setting $f_\infty(\eta) = u_\infty(x/\sqrt{\ell}, 1)$ with $\eta = x/\sqrt{\ell}$, it is straightforward that $f_\infty$ satisfies (2.38) (using in particular 2.39). Furthermore $f_\infty$ is radial and positive as the $u_k$ are.

□

Lemma 2.7 The function $f_\infty$ satisfies
$$f_\infty(\eta) = c|\eta|^{2\gamma-N}e^{-|\eta|^2/4}(1 + o(|\eta|^{-2})) \quad \text{as } |\eta| \to \infty,$$  
(2.43)

for some $c = c_{N,p,\beta} > 0$. Furthermore
$$f_\infty'(\eta) = -\frac{c}{2}|\eta|^{2\gamma+1-N}e^{-|\eta|^2/4}(1 + o(|\eta|^{-2})) \quad \text{as } |\eta| \to \infty.$$  
(2.44)

Proof. Set $r = |\eta|$ and denote $f_\infty(\eta) = f_\infty(r)$. Then $f_\infty$ satisfies,
$$f''_\infty + \left(\frac{N-1}{r} + \frac{r}{2}\right)f'_\infty + \gamma f_\infty - r^\beta|f_\infty|^{p-1}f_\infty = 0 \quad \text{on } (0, \infty),$$  
(2.45)

and $\lim_{r \to \infty}r^{2\gamma}f_\infty(r) = 0$. We consider the auxiliary equation
$$f'' + \left(\frac{N-1}{r} + \frac{r}{2}\right)f' + \gamma f = 0 \quad \text{on } (0, \infty).$$  
(2.46)

By [10, Prop A1], (2.46) admits two linearly independent solutions defined on $(0, \infty)$, $y_1$ and $y_2$ such that
$$y_1(r) = r^{-2\gamma}(1 + o(1)) \quad \text{and} \quad y_2(r) = r^{2\gamma-N}e^{-r^2/4}(1 + o(1)),$$  
(2.47)

as $r \to \infty$. Next we choose $R > 0$ large enough so that the maximum principle applies for equation (2.46) on $[R, \infty)$ and the $y_j$ are positive on the same interval. For $\delta > 0$, $Y_\delta = \delta y_1 + f_\infty(R)y_2/y_2(R)$ is a supersolution for (2.45). Furthermore $f_\infty(r) = o(Y_\delta)$ at infinity. Letting $\delta \to 0$ yields to
$$f_\infty(r) \leq \frac{f_\infty(R)}{y_2(R)}y_2(r) \quad \forall r \geq R.$$  
(2.48)

Using (2.47) we derive
$$0 \leq f_\infty(\eta) \leq C|\eta|^{2\gamma-N}e^{-|\eta|^2/4} \quad \forall |\eta| \geq 1.$$  

Plugging this estimate into (2.45), we derive (2.43) from standard perturbation theory for second order linear differential equation [2, p. 132-133]. Finally, (2.44) follows directly from (2.43) and (2.45).

□

An alternative proof of the existence of $f_\infty$ is linked to calculus of variations. In the case $\beta = 0$, this was performed by Escobedo and Kavian [8]. This construction is based upon the study of the following functional
$$J(\upsilon) = \frac{1}{2} \int_{\mathbb{R}^N} \left(\nabla \upsilon \cdot \nabla \upsilon - \gamma \upsilon^2 + \frac{2}{p+1}|\upsilon|^\beta|\upsilon|^{p+1}\right)K(\eta)d\eta,$$  
(2.49)

defined over the functions in $H^1_k(\mathbb{R}^N) \cap L^{p+1}_{\eta^\beta\gamma}(\mathbb{R}^N)$.
Proposition 2.8 Assume \( p > 1 \) and \( \beta > N(p-1) - 2 \). Then there exists a positive function \( f_\infty \in H^1_k(\mathbb{R}^N) \cap L^{p+1}_K(\mathbb{R}^N) \) satisfying

\[
-\Delta f_\infty - \frac{1}{2} \eta \nabla f_\infty - \gamma f_\infty + |\eta|^\beta f_\infty = 0 \quad \text{in} \ \mathbb{R}^N. 
\] (2.50)

We recall that the eigenvalues of \(-K^{-1} \text{div}(K \nabla \cdot)\) are the \( \lambda_k = (N + k)/2 \), with \( k \in \mathbb{N} \) and the eigenspaces \( H_k \) are generated by \( D^\alpha \phi \) where \( \phi(\eta) = K^{-1}(\eta) = e^{-|\eta|^2/4} \) and \( |\alpha| = k \). It is straightforward to check that \( J \) is \( C^1 \). In order to apply Ekeland Lemma, we have just to prove that \( J \) is bounded from below in \( H^1_k(\mathbb{R}^N) \). As we shall see it later on, the proof is easy when \( \beta < N(p-1)/2 \), and more difficult when \( \beta \geq N(p-1)/2 \).

Lemma 2.9 For any \( v \in H^1_k(\mathbb{R}^N) \), there holds

\[
\frac{1}{4} \int_{\mathbb{R}^N} (2N + |\eta|^2) v^2 K(\eta) d\eta \leq \int_{\mathbb{R}^N} |\nabla v|^2 K(\eta) d\eta.
\]

Proof. We borrow the proof to Escobedo and Kavian. Put \( w = v \sqrt{K} \). Then

\[
\sqrt{K} \nabla v = \nabla w - \frac{w}{2} \eta.
\]

Hence

\[
\int_{\mathbb{R}^N} |\nabla v|^2 K(\eta) d\eta = \int_{\mathbb{R}^N} \left( |\nabla w|^2 - w \nabla w \cdot \eta + \frac{1}{4} w^2 |\eta|^2 \right) d\eta.
\]

Because

\[
-\int_{\mathbb{R}^N} w \nabla w \cdot \eta d\eta = \frac{N}{2} \int_{\mathbb{R}^N} w^2 d\eta,
\]

there holds

\[
\int_{\mathbb{R}^N} |\nabla v|^2 K(\eta) d\eta = \int_{\mathbb{R}^N} \left( |\nabla w|^2 + \frac{N}{2} w^2 + \frac{1}{4} w^2 |\eta|^2 \right) d\eta.
\]

This implies the formula. \( \Box \)

Lemma 2.10 Let \( p > 1 \) and \( \beta < N(p-1)/2 \). For any \( \epsilon > 0 \) there exists \( C = C(\epsilon, p) > 0 \) and \( R = R(\epsilon, p) > 0 \) such that

\[
\int_{\mathbb{R}^N} v^2 K(\eta) d\eta \leq \epsilon \int_{\mathbb{R}^N} |\nabla v|^2 K(\eta) d\eta + C \left( \int_{\mathbb{R}^N} |v|^{p+1} |\eta|^\beta K(\eta) d\eta \right)^{2/(p+1)}.
\]

Proof. For \( R > 0 \) there holds

\[
\int_{|\eta| \leq R} v^2 K(\eta) d\eta \leq \left( \int_{|\eta| \leq R} |v|^{p+1} |\eta|^\beta K(\eta) d\eta \right)^{2/(p+1)} \left( \int_{|\eta| \leq R} |\eta|^{-2\beta/(p-1)} K(\eta) d\eta \right)^{(p-1)/(p+1)}.
\]

Since \( \beta < N(p-1)/2 \iff N > 2\beta/(p-1) \), we obtain

\[
\left( \int_{|\eta| \leq R} |\eta|^{-2\beta/(p-1)} K(\eta) d\eta \right)^{(p-1)/(p+1)} = C(R, N, p).
\]

By Lemma 2.9

\[
\int_{|\eta| \geq R} v^2 K(\eta) d\eta \leq \frac{4}{R^2} \int_{\mathbb{R}^N} |\nabla v|^2 K(\eta) d\eta.
\]
The estimate follows by taking $\epsilon = 4R^{-2}$. \(\square\)

It follows from the previous Lemmas that $J$ is bounded from below in the space $H^1_{p,K}(\mathbb{R}^N) \cap L^{p+1}_{|x|^\beta K}(\mathbb{R}^N)$ whenever $N(p-1)/2-2<\beta<N(p-1)/2$. Next we consider the case $\beta > 0$ and we shall restrict the study to radial functions.

**Lemma 2.11** Assume $\beta > 0$. The functional $J$ is bounded from below on the set

$$X = \left\{ v \in H^1_{p,K}(\mathbb{R}^N) \cap L^{p+1}_{|x|^\beta K}(\mathbb{R}^N) : v \geq 0, v \text{ radial and decreasing} \right\}.$$  

*Proof.* For $0 < \delta < R$, we write $J(v) = J_{\delta,R}(v) + J'_{\delta,R}(v) + J''_{\delta,R}(v)$ where

$$J_{\delta,R}(v) = \frac{1}{2} \int_{|x| \leq \delta} \left| \nabla v \right|^2 - \gamma v^2 + \frac{2}{p+1} |\eta|^{\beta |v|^{p+1}} K(\eta) d\eta,$$

$$J'_{\delta,R}(v) = \frac{1}{2} \int_{\delta <|x| < R} \left| \nabla v \right|^2 - \gamma v^2 + \frac{2}{p+1} |\eta|^{\beta |v|^{p+1}} K(\eta) d\eta,$$

and

$$J''_{\delta,R}(v) = \frac{1}{2} \int_{|x| > R} \left( \left| \nabla v \right|^2 - \gamma v^2 + \frac{2}{p+1} |\eta|^{\beta |v|^{p+1}} \right) K(\eta) d\eta.$$

Using Lemma 2.10, we fix $R$ large enough so that $J''_{\delta,R}$ is bounded from below in $H^1_{p,K}(\mathbb{R}^N) \cap L^{p+1}_{|x|^\beta K}(\mathbb{R}^N)$. By Hölder’s inequality $J'_{\delta,R}$ is bounded from below, thus we are left with $J_{\delta,R}$. We assume that $v$ is positive, radial, nonincreasing and $v(\delta) = c = \min\{ v(x) : |x| \leq \delta \}$. Then

$$|v|^{p+1} = v^{p+1} = (v-c)^{p+1} \geq (v-c)^{p+1} + \epsilon^{p+1} \text{ and } v^2 \leq 2(v-c)^2 + 2c^2,$$

$$J_{\delta,R} \geq \frac{1}{2} \int_{|x| \leq \delta} \left| \nabla (v-c) \right|^2 - 2\gamma(v-c)^2 + \frac{2}{p+1} |\eta|^{\beta |v-c|^{p+1}} K(\eta) d\eta + L(c),$$

where

$$L(c) = \frac{\epsilon^{p+1}}{p+1} \int_{|x| \leq \delta} |\eta|^{\beta} K(\eta) d\eta - \gamma c^2 \int_{|x| \leq \delta} K(\eta) d\eta.$$  

Clearly $L(c) \geq M$ for some $M$ independent of $c$. Therefore we are reduced to study the functional $J_{\delta,R}$ defined by

$$J_{\delta,R}(w) = \frac{1}{2} \int_{|x| \leq \delta} \left( \left| \nabla w \right|^2 - 2\gamma w^2 + \frac{2}{p+1} |\eta|^{\beta |w|^{p+1}} \right) K(\eta) d\eta$$

over $H^1_{0,K}(B_{\delta}) \cap L^{p+1}_{|x|^\beta K}(B_{\delta})$. Here we can fix $\delta > 0$ small enough so that the first eigenvalue of $-\operatorname{div}(K\nabla .)$ is larger than $2\gamma$, thus $J_{\delta,R}(v)$ is bounded from below in the class of radially symmetric nonincreasing, nonnegative functions $v$, and so is $J$. \(\square\)

**Lemma 2.12** Let $v$ be a radially symmetric function in $H^1_{p,K}(\mathbb{R}^N) \cap L^{p+1}_{|x|^\beta K}(\mathbb{R}^N)$. Then there exists a radially symmetric decreasing function $\tilde{v} \in H^1_{p,K}(\mathbb{R}^N) \cap L^{p+1}_{|x|^\beta K}(\mathbb{R}^N)$ such that $J(\tilde{v}) \leq J(v)$.

*Proof.* We define the two curves

$$C_1 = \left\{ (s,x) \in \mathbb{R}_+ \times \mathbb{R}_+ : -2^{-1} \gamma x^2 + (p+1)^{-1} s^{\beta} x^{p+1} = 0 \right\} = \left\{ x = \left( 2^{-1}(p+1)\gamma s^{-\beta} \right)^{1/(p-1)} \right\},$$
and
\[ C_2 = \{(s,x) \in \mathbb{R}_+ \times \mathbb{R}_+ : -\gamma x + s^\beta x^p = 0\} = \left\{ x = (\gamma s^{-\beta})^{1/(p-1)} \right\}. \]

For fixed \( s > 0 \) the function \( x \mapsto -2^{-1}\gamma x^2 + (p+1)^{-1}s^\beta x^{p+1} \) vanishes at \( x = 0 \). It has the following properties:

(i) it is decreasing for \( 0 < x < (\gamma s^{-\beta})^{1/(p-1)} \),

(ii) it achieves a minimum at \( x_s = (2^{-1}(p+1)\gamma s^{-\beta})^{1/(p-1)} \),

(iii) and it is increasing for \( x > (\gamma s^{-\beta})^{1/(p-1)} \) with infinite limit. Furthermore it vanishes at \( x = (2^{-1}(p+1)\gamma s^{-\beta})^{1/(p-1)} \).

Let \( v \) be a radially symmetric positive function. By approximation of radial elements in \( H^1_{0,K}(\mathbb{R}^N) \cap L^{p+1}_{|\cdot|^\gamma K}(\mathbb{R}^N) \), we can assume that \( v \) is \( C^2 \) with nondegenerate isolated extrema.

We can also assume that the graph of \( v \) has at most a countable of intersections with \( C_2 \), \( a_1 < a_2 < a_3 \ldots < a_k < \ldots \), that the set of points \( \{a_k\} \) is discrete, that all the intersections are transverse and that, for every \( j \geq 0 \),
\[ v(s) < (\gamma s^{-\beta})^{1/(p-1)} \quad \text{on} \quad (a_{2j}, a_{2j+1}), \]

where \( a_0 = 0 \), and
\[ v(s) > (\gamma s^{-\beta})^{1/(p-1)} \quad \text{on} \quad (a_{2j+1}, a_{2j+2+1}). \]

The modifications of the function \( v \) is performed by local modification on each interval \((a_k,a_{k+1})\):

\textbf{Step 1-} The construction of \( \tilde{v} \) on \( (a_{2j}, a_{2j+1}) \) is as follows. Let \( a_1 < a_2 < \ldots \) be the sequence of local extrema of \( v \), with \( v(a_{2i+1}) \) local minimum and \( v(a_{2i+2}) \) local maximum. By extension, since \( v'(a_{2j+1}) > -\beta/(p-1)\gamma^{1/(p-1)}a_{2j+1}^{-(\beta+p-1)/(p-1)} \), \( v(a_{2j+1}) \) is a local maximum of \( v \) on \( (a_{2j}, a_{2j+1}) \).

If \( \max\{v(a_{2i+1}) : i \geq 1\} \leq v(a_{2j+1}) \), then \( \tilde{v} = \max\{v, v(a_{2j+1})\} \).

If \( \max\{v(a_{2i+1}) : i \geq 1\} > v(a_{2j+1}) \), we define the increasing sequence \( \{a_{2i+1}\} \) by
\[ v(a_{2i+1}) = \max\{v(a_{2i+1}) : i \geq 0\}, \]
\[ v(a_{2i+1}) \max\{v(a_{2i+1}) : i > i_0\}, \]

and by induction,
\[ v(a_{2i+1}) \max\{v(a_{2i+1}) : i > i_{i-1}\}. \]

Thus we can assume that the local maxima of \( v \) are less than \( v(a_{2j+1}) \) on the last interval \((a_{2i+1}, a_{2j+1})\). Next we define the function \( \tilde{v} \) by \( \tilde{v} = \max\{v, v(a_{2i+1}) \} \) on \((a_{2j}, a_{2i+1})\), \( \tilde{v} = \max\{v, v(a_{2i+1}) \} \) on \((a_{2i+1}, a_{2i+1})\). By induction, \( \tilde{v} = \max\{v, v(a_{2i+1}) \} \) on \((a_{2i+1}, a_{2i+1})\). Finally \( \tilde{v} = \max\{v, v(a_{2i+1}) \} \) on the last interval \((a_{2i+1}, a_{2j+1})\). The function \( \tilde{v} \) is Lipschitz continuous, nonincreasing and, because \( v(s) \leq \tilde{v}(s) \leq (\gamma s^{-\beta})^{1/(p-1)} \), there holds
\[ \int_{a_{2j} \leq \eta \leq a_{2j+1}} \left( |\nabla \tilde{v}|^2 - \gamma \tilde{v}^2 + \frac{2}{p+1} |\eta|^\gamma |\tilde{v}|^{p+1} \right) K(\eta) d\eta \]
\[ \leq \int_{a_{2j} \leq \eta \leq a_{2j+1}} \left( |\nabla v|^2 - \gamma v^2 + \frac{2}{p+1} |\eta|^\gamma |v|^{p+1} \right) K(\eta) d\eta. \]  

\textbf{Step 2-} The construction of \( \tilde{v} \) on \((a_{2j+1}, a_{2j+2})\) follows the same principle. Let \( \beta_1 < \beta_2 < \ldots < \beta_d \) be the sequence of local minima of \( v \) on this interval. Furthermore \( v(a_{2j+1}) \) is the minimum of \( v \) on \((a_{2j+1}, a_{2j+2})\) and \( v'(a_{2j+2}) < -\beta/(p-1)\gamma^{1/(p-1)}a_{2j+2}^{-(\beta+p-1)/(p-1)} \).
On \((a_{2j+1}, \beta_1)\) we set \(\tilde{v} = \min\{v, v(a_{2j+1})\}\). On \((\beta_1, \beta_2)\), \(\tilde{v} = \min\{v, \tilde{v}(\beta_1)\}\). By induction \(\tilde{v} = \min\{v, \tilde{v}(\beta_1)\}\) on \((\beta_1, b_{2j+1})\). On the last interval \((b_0, b_{2j+1})\), \(\tilde{v} = \min\{v, \tilde{v}(\beta_d)\}\). Because \(\tilde{v} \leq v\) on this interval and \(x \mapsto -2^{-1} \gamma x^2 + (p+1)^{-1} s^\beta x^{p+1}\) is increasing above the curve \(C_2\), we obtain similarly

\[
\int_{a_{2j+1} \leq \eta \leq a_{2j+2}} (|\nabla \tilde{v}|^2 - \gamma \tilde{v}^2 + \frac{2}{p+1} |\eta|^\beta |\tilde{v}|^{p+1}) K(\eta) d\eta \leq \int_{a_{2j+1} \leq \eta \leq a_{2j+2}} (|\nabla v|^2 - \gamma v^2 + \frac{2}{p+1} |\eta|^\beta |v|^{p+1}) K(\eta) d\eta.
\]  

(252)

By construction \(\tilde{v}\) is nonincreasing. Combining (251) and (252), we obtain \(J(\tilde{v}) \leq J(v)\).

\[\square\]

**Proof of Proposition 2.8.** It follows from the previous lemmas that \(J\) is bounded from below on \(X\) and the function \(\phi = K^{-1}\) belongs to \(X\). Furthermore

\[J(t\phi) = \left(\frac{N - 2\gamma}{4}\right) t^2 \int K^{-1}(\eta) d\eta + \frac{2}{p+1} \int \phi^p(\eta) d\eta.\]

Since \(\beta > N(p - 1) - 2 \iff N - 2\gamma < 0\), the infimum \(m\) of \(J\) over radially symmetric functions is negative but finite and achieved by a decreasing function. Let \(\{v_n\} \subset X\) a sequence such that \(J(v_n) \downarrow m\). Then \(\{v_n\}\) remains bounded in \(H^1_K(\mathbb{R}^N) \cap L^{p+1}_{|\eta|^\beta K}(\mathbb{R}^N)\). Up to a subsequence we can assume that \(v_n\) converges weakly in \(H^1_K(\mathbb{R}^N)\) and in \(L^{p+1}_{|\eta|^\beta K}(\mathbb{R}^N)\) and strongly in \(L^p_K(\mathbb{R}^N)\) to some function \(v\). Moreover this convergence holds a.e., and, since \(v_n \in X\) the same holds with \(v\). Going to the limit in the functional yields to

\[J(v) \leq \liminf_{n \to \infty} J(v_n) = m;\]

thus \(v\) is a critical point.

\[\square\]

The following uniqueness result holds.

**Proposition 2.13** Assume \(p > 1\) and \(\beta > N(p - 1) - 2\). Then \(f_\infty = f_\infty\). Furthermore \(f_\infty\) is the unique positive solution of (2.38).

**Proof.** We first prove that \(f_\infty\) is the unique positive radial solution of (2.50) belonging to \(H^1_K(\mathbb{R}^N) \cap L^{p+1}_{|\eta|^\beta K}(\mathbb{R}^N)\). We denote \(r = |\eta|\) and \(f_\infty(\eta) = f_\infty(r)\). Let \(\tilde{f}\) be another solution in the same class. Thus there exists \(\{r_n\}\) converging to \(\infty\) such that \(\tilde{f}(r_n) \to 0\). For \(\epsilon > 0\), set \(\tilde{f}_\epsilon = f_\infty + \epsilon\). For \(n \geq n_0\), large enough, \(w_+(r_n) = 0\), thus, as in the proof of Proposition 2.1,

\[
\int_{B_{r_n}} \left( |\nabla \tilde{f} - \tilde{f}_\epsilon \nabla \tilde{f}_\epsilon|^2 + |\nabla \tilde{f}_\epsilon - \tilde{f}_\epsilon \nabla f|^2 \right) K d\eta + \gamma \int_{B_{r_n}} \int_{r \in (f_\infty(\tilde{f}_\epsilon) - f_\infty(\tilde{f}_\epsilon))^+} K d\eta 
\]

\[
+ \int_{B_{r_n}} |\eta|^\beta (f_\infty(\tilde{f}_\epsilon) - f_\infty(\tilde{f}_\epsilon))^+ (f_\infty(\tilde{f}_\epsilon) - f_\infty(\tilde{f}_\epsilon))^+ K d\eta \leq 0.
\]

We let successively \(r_n \to \infty\) with Fatou’s lemma, and \(\epsilon \to 0\) with Lebesgue’s theorem, since \(\epsilon/\tilde{f}_\epsilon \leq 1\) and \((f_\infty(\tilde{f}_\epsilon) - f_\infty(\tilde{f}_\epsilon))^+ \leq \tilde{f} + f_\infty^2 \in L^p_K(\mathbb{R}^N)\). We get

\[
\int_{\mathbb{R}^N} \left( |\nabla \tilde{f} - f_\infty \nabla f_\infty|^2 + |\nabla f_\infty - f_\infty \nabla f|^2 + |\eta|^\beta (f_\infty(\tilde{f}_\epsilon) - f_\infty(\tilde{f}_\epsilon))^+ (f_\infty(\tilde{f}_\epsilon) - f_\infty(\tilde{f}_\epsilon))^+ \right) K d\eta \leq 0,
\]
which implies \( \hat{f} \leq \hat{f}_\infty \). In the same way \( \hat{f}_\infty \leq \hat{f} \). By Lemma 2.7, \( f_\infty \in H_K^1(\mathbb{R}^N) \cap L_{[0]}^{p+1}(\mathbb{R}^N) \). Thus \( f_\infty = \hat{f}_\infty \).

We end this section with a classification result

**Theorem 2.14** Assume \( p > 1 \) and \( \beta > N(p-1) - 2 \) and let \( u \) be a positive solution of (2.1) which satisfies (2.27). Then,

(i) either there exists \( k \geq 0 \) such that \( u = u_k \),

(ii) or \( u = u_\infty \).

**Proof.** Because of (2.27), the initial trace \( tr(u) \) of \( u \) is a outer regular Borel measure concentrated at 0 (see [12]). Then either the initial trace is a Radon measure, say \( k\delta_0 \), and we get (i), or

\[
\lim_{t \to 0} \int_{B_1} u(x, t) dx = \infty,
\]

for every \( \epsilon > 0 \). This implies \( u \geq u_\infty \) as in [11]. Notice that, in this article, this estimate is performed in the case \( \beta = 0 \), but the proof in the general case is the same. In order to prove that \( u \leq u_\infty \), we consider, for \( \epsilon > 0 \), the minimal solution \( v := v_\epsilon \) of

\[
\begin{cases}
\partial_t v - \Delta v + |x|^\beta |v|^{p-1} v = 0 & \text{in } Q_T \\
tr(v) = \nu_{B_1},
\end{cases}
\]

where \( \nu_{B_1} \) is the outer regular Borel measure such that \( \nu_{B_1}(E) = 0 \) for any Borel set \( E \subset \mathbb{R}^N \) such that \( E \cap B_1 = \emptyset \), and \( \nu_{B_1}(E) = \infty \) otherwhile. This solution is constructed as the limit, when \( m \to \infty \) of the solution \( v_{\epsilon,m} \) of (2.1) verifying \( v_{\epsilon,m}(\cdot, 0) = m\chi_{B_1} \). Clearly \( u \leq v_\epsilon \). Furthermore, for any \( \ell > 0 \),

\[
T_\ell[v_{\epsilon,m}] = v_{\epsilon/\sqrt{\ell}, m\ell^{(2+\beta)/2(p-1)}} \Rightarrow T_\ell[v_\epsilon] = v_{\epsilon/\sqrt{\ell}} \Rightarrow T_\ell[v_0] = v_0,
\]

where \( v_0 = \lim_{\epsilon \to 0} v_\epsilon \). This, and the fact that \( \lim_{\epsilon \to 0} v_0(x, t) = 0 \) for every \( x \in \mathbb{R}^N \setminus \{0\} \), imply that \( v_0(x, t) = t^{-(2+\beta)/2(p-1)} f_\infty(x/\sqrt{t}) = u_\infty(x, t) \). At the end, since \( u \leq v_\epsilon \Rightarrow u \leq v_0 \), it follows \( u \leq u_\infty \). \( \square \)

### 3 Existence of very singular solutions

In this section, we study the singular set of the solution \( u_\infty \), in the case of strongly degenerate potential (1.9), using some variant of the local energy estimate (abr. L.E.E.) method in the spirit of Saint-Venant’s principle. The L.E.E. technique was first used for singular solutions of quasilinear parabolic equations in [15]. An adaption of this method to the study of conditions of removability of the point singularities of solutions of the quasilinear parabolic equations of diffusion-strong absorption type was presented in [9]. In [14] there was elaborated a variant of the L.E.E. method, which allowed to find sharp conditions on the time dependent absorption potential, guaranteing existence of very singular solutions of the Cauchy problem to diffusion-strong absorption type equation with point singularity set. Here we provide a new application of the L.E.E. method in describing the transformation of V.S.S solution into the R.B. solution in terms of the flatness of the absorption potential in the space variables.

We consider the sequence of the Cauchy problems

\[
    u_t - \Delta u + h(|x|) |u|^{p-1} u = 0 \quad \text{in } \mathbb{R}^N \times (0, T), \; p > 1,
\]

(3.1)
\[ u(x, 0) = u_{0,k}(x) = M_k \exp(-2^{-1}\mu_0 Nk) \delta_k(x), \] (3.2)

where \( \delta_k \) is a regularized Dirac measure: \( \delta_k \in C(\mathbb{R}^N) \), \( \delta_k \rightharpoonup \delta \) weakly in the sense of measures as \( k \to \infty \),

\[ \text{supp} \delta_k \subset \{ x : |x| \leq \exp(-\mu_0 k) \} \quad \forall k \in \mathbb{N}, \] (3.3)

where the constant \( \mu_0 > 0 \) will be defined later on, and

\[ M_k = \exp \exp k \quad \forall k \in \mathbb{N}. \] (3.4)

Without loss of generality we suppose that

\[ \| \delta_k \|_{L^2(\mathbb{R}^N)}^2 \leq \exp(\mu_0 Nk). \] (3.5)

We write the potential \( h \) in the equation (3.1) under the form,

\[ h(s) = \exp(-\omega(s)s^{-2}) \quad \forall s \geq 0, \] (3.6)

where \( \omega(s) \geq 0 \) is arbitrary nondecreasing function on \([0, \infty)\).

**Theorem 3.1** Let the function \( \omega(s) \) defined in (3.6) satisfy additionally the following Dini-like condition

\[ \int d_1 \omega(s)s^{-1} ds \leq d_2 < \infty, \quad d_1 = \text{const} > 0, \] (3.7)

and the following technical condition

\[ \frac{s \omega'(s)}{\omega(s)} \leq 2 - \alpha_0 \quad \forall s \in (0, s_0), \quad s_0 > 0, \quad 0 < \alpha_0 = \text{const} < 2. \] (3.8)

Then the following a priori estimate of solutions \( u_k \) of the problem (3.1), (3.2), (3.5), holds uniformly with respect to \( k \in \mathbb{N} \),

\[ \int_{\mathbb{R}^N} |u_k(x, t)|^2 dx \leq C_1 t \exp \left[ C_2 \left( \Phi^{-1} \left( \frac{t}{C_3} \right) \right)^{-2} \right], \] (3.9)

where the constants \( C_1 > 0, C_2 > 0, C_3 > 0 \) do not depend on \( k \). Here \( \Phi^{-1}(s) \) is the inverse function to

\[ s \mapsto \Phi(s) := \int_0^s \frac{\omega(r)}{r} d\tau. \]

Let us define the following families of domains

\[ B(s) := \{ x : |x| < s \}, \quad \Omega(s) := \mathbb{R}^N \setminus B(s), \]

\[ Q^2_{12}(s) := \Omega(s) \times (t_1, t_2), \quad \forall s > 0, \quad \forall 0 \leq t_1 < t_2 \leq T. \]

Let \( u(x, t) \equiv u_k(x, t) \) be a solution of the problem (3.1), (3.2) under consideration. We introduce the energy functions

\[ I(s, \tau) := \int_0^\tau \int_{\Omega(s)} \left( |\nabla_x u|^2 + h(|x|)|u|^{p+1} \right) dx \ dt, \] (3.10)

and

\[ J(s, t) = \int_{\Omega(s)} |u(x, t)|^2 dx, \quad E(s, t) = \int_{B(s)} |u(x, t)|^2 dx. \] (3.11)
Lemma 3.2 The energy functions $J(s,t), I(s,t)$ defined by (3.10), (3.11) corresponding to an arbitrary solution $u = u_k$ of problem (3.1), (3.2) satisfy the following a priori estimate

$$J(s,t) + I(s,t) \leq c t g(s) := c t \left( \int_0^s r^{-\frac{(N-1)(p-1)}{2(p+1)}} h(r) \frac{dr}{r} \right)^{\frac{p+1}{p-1}}, \quad \forall s \geq \exp(-\mu_0 k) \tag{3.12}$$

uniformly with respect to $k \in \mathbb{N}$.

By $c, c_1$ we denote different positive constants, which depend on known parameters $N, p, \alpha_0, d_2$ only, and their value may change from lines to lines.

Proof. Multiplying equation (3.1) by $u$ and integrating in $Q_{t_1}(s)$, we obtain the following starting relation after standard computations,

$$2^{-1} \int_{Q_{t_1}(s)} |u(x,t_2)|^2 dx + \int_{Q_{t_1}(s)} (|\nabla_x u|^2 + h(|x|) |u|^{p+1}) dx dt =$$

$$= 2^{-1} \int_{Q_{t_1}(s)} |u(x,t_1)|^2 dx + \int_{t_1}^{t_2} \int_{|x|=s} \frac{\partial u}{\partial n} d\sigma dt := R_0 + R_1. \tag{3.13}$$

Let us estimate $R_1$ from above. Using Holder’s and Young’s inequalities we have

$$\left| \int_{|x|=s} u(x,t) \frac{\partial u}{\partial n} d\sigma \right| \leq c s^{\frac{(N-1)(p-1)}{2(p+1)}} \left( \int_{|x|=s} |\nabla_x u|^2 d\sigma \right)^{1/2} \left( \int_{|x|=s} |u|^{p+1} d\sigma \right)^{1/2} \leq$$

$$\leq c s^{\frac{(N-1)(p-1)}{2(p+1)}} h(s)^{\frac{p+1}{p-1}} \left( \int_{|x|=s} (|\nabla_x u|^2 + h(s) |u|^{p+1}) d\sigma \right)^{\frac{p+3}{2(p+1)}}.$$

Integrating in $t$, we get

$$\left| \int_0^\tau \int_{|x|=s} \frac{\partial u}{\partial n} d\sigma dt \right| \leq c s^{\frac{(N-1)(p-1)}{2(p+1)}} h(s)^{\frac{p+1}{p-1}} \left( \int_0^\tau \int_{|x|=s} (|\nabla_x u|^2 + h(s) |u|^{p+1}) d\sigma dt \right)^{\frac{p+3}{2(p+1)}}. \tag{3.14}$$

It is easy to see that

$$-\frac{d}{ds} I(s, \tau) = \int_0^\tau \int_{|x|=s} (|\nabla_x u|^2 + h(s) |u|^{p+1}) \, ds, \quad -\frac{d}{ds} J(s, t) \geq 0.$$

Because of the property (3.3) satisfied by $u_{0,k}$, and estimate (3.14), we derive the following inequality from relation (3.13) with $t_2 = t_1 = 0$, $s \geq \exp(-\mu_0 k),$

$$J(s,t) + I(s,t) \leq c t^{\frac{p-1}{2(p+1)}} h(s)^{\frac{p+1}{p-1}} \left( -\frac{d}{ds} (I(s,t) + J(s,t)) \right)^{\frac{p+3}{2(p+1)}}, \tag{3.15}$$

Solving this ordinary differential inequality (abr. O.D.I.) with respect to the function $I(s,t) + J(s,t)$, we deduce that estimate (3.12) holds for arbitrary $s \geq \exp(-\mu_0 k)$.

Next, we define $s_k > 0$ by the relation

$$g(s_k) = M_k^{c_0} = \exp(c_0 \exp k), \tag{3.16}$$
where $0 < \varepsilon_0 < 1$ will be defined later on. Now we have to guarantee that
\[ s_k \geq \exp(-\mu_0 k) := \overline{s}_k \quad \forall k > k_0(\varepsilon_0, \alpha_0, \nu_0, p). \]  
(3.17)

Using [1, Lemma A1], it follows from the definitions (3.6) of function $h(.)$ and (3.12) of function $g(.)$, that the next estimate holds,
\[ \left(\frac{2\alpha_0}{p + 3}\right) \frac{s^{p + 3}}{\mu^{p + 3}} g_1(s) \leq g(s) \leq \left(\frac{4}{p + 3}\right) \frac{s^{p + 3}}{\mu^{p + 3}} g_1(s), \]  
(3.18)

where $g_1(s) = s^{N-1-\frac{2(p+1)}{p-1}} \omega(s) s^{p+1} \exp\left(\frac{2}{p-1}\frac{\omega(s)}{s^2}\right)$, $\alpha_0$ is constant from condition (3.8). The following simpler estimate follows from (3.18):
\[ \exp\left(\frac{\omega(s)}{s^2} \frac{2}{p-1} (1 - \nu_0)\right) \leq g(s) \leq \exp\left(\frac{\omega(s)}{s^2} \frac{2}{p-1} (1 + \nu_0)\right), \]  
(3.19)

for any $s \in (0, s_0)$, where $s_0 = s_0(\nu_0) \to 0$ as $\nu_0 \to 0$. As a consequence of definition (3.16) of $s_k$, and using (3.19), we get,
\[ \frac{\omega(s_k)}{s_k^2} \frac{2(1 - \nu_0)}{p-1} \leq \varepsilon_0 \exp k. \]  
(3.20)

Integrating (3.8), we deduce that $\omega$ satisfies
\[ \omega(s) \geq s^{2-\alpha_0} \quad \forall s > 0. \]  
(3.21)

Combining (3.21) and (3.20) we derive:
\[ s_k \geq \left(\frac{2(1 - \nu_0)}{\varepsilon_0(p-1)}\right) \frac{s}{\mu} \exp\left(-\frac{k}{\alpha_0}\right). \]  
(3.22)

Next we define $\mu_0$ from (3.2) and set $\mu_0 = 2\alpha_0^{-1}$. It follows from (3.22) that (3.17) is satisfied for all $k > k_0(\varepsilon_0, \alpha_0, \nu_0, p)$. As result we derive that estimate (3.12) obtained in Lemma 3.2 is valid for $s = s_k$, i.e.
\[ J(s_k, t) + I(s_k, t) \leq c \sigma g(s_k) \quad \forall k \geq k_0 = k_0(\varepsilon_0, \alpha_0, \nu_0, p). \]  
(3.23)

In order to find estimates characterizing the behaviour of the energy function $E(s_k, t)$ with respect to the variable $t > 0$, we introduce the nonnegative cut-off function $\varphi_k \in C^1(\mathbb{R})$ defined by
\[ \varphi_k(s) = 1 \text{ if } s < s_k, \quad \varphi_k(s) = 0 \text{ if } s \geq 2s_k, \quad \varphi_k(s) \leq cs_k^{-1}. \]  
(3.24)

Multiplying (3.1) by $u_k \varphi_k^2(|x|)$ and integrating with respect to $x$, we get
\[ 2^{1-d} \int_{\mathbb{R}^N} u^2(x, t) \varphi_k^2(|x|) dx + \int_{\mathbb{R}^N} |\nabla x(u \varphi_k)|^2 dx + \int_{\mathbb{R}^N} h(|x|) \varphi_k^2 |u|^{p+1} dx \leq \int_{\mathbb{R}^N} u^2(x, t) |\nabla x \varphi_k(|x|)|^2 dx := \mathbb{R}_1. \]  
(3.25)

By (3.24) and (3.23), we obtain
\[ \mathbb{R}_1 \leq c_1 s_k^{-2} \int_{s_k < |x| < 2s_k} |u(x, t)|^2 dx \leq c_2 s_k^{-2} J(s_k, t) \leq c_3 s_k^{-2} t g(s_k). \]  
(3.26)
Using (3.25), (3.26) and Poincaré’s inequality we derive the following differential inequality,

\[
\frac{d}{dt} \left( \int_{\mathbb{R}^N} u^2(x,t) \varphi_k^2 dx \right) + d_0 s_k^{-2} \int_{B(2s_k)} u^2(x,t) \varphi_k^2 dx \leq \tau s_k^{-2} \gamma g(s_k), \quad d_0 > 0.
\]  

(3.27)

If we set

\[
\psi_k(t) := \int_{\mathbb{R}^N} |u_k(x,t)|^2 \varphi_k^2(|x|) dx,
\]

it is straightforward that (3.27) implies that the following O.D.I. holds,

\[
\psi_k'(t) + d_0 s_k^{-2} \psi_k(t) \leq \tau s_k^{-2} \gamma g(s_k);
\]  

(3.28)

furthermore, we can rewrite (3.28) under the form

\[
\psi_k'(t) + \frac{d_0}{2} s_k^{-2} \psi_k(t) + 2^{-1} \left( d_0 s_k^{-2} \psi_k(t) - \tau s_k^{-2} \gamma g(s_k) \right) \leq 0.
\]  

(3.29)

Using the relations (3.2), (3.5) satisfied by \(u_k\), we see that \(\psi_k\) verifies,

\[
\psi_k(0) \leq \int_{\mathbb{R}^N} |u_{k,0}(x)|^2 dx \leq M_k.
\]  

(3.30)

At last, we define the \(t_k\) by

\[
t_k = \gamma \omega(s_k)
\]  

(3.31)

where \(\omega\) is the function in (3.6) and \(\gamma > 0\) is a parameter which will be made precise in the next lemma.

**Lemma 3.3** There exists a constant \(\gamma > 0\), which does not depend on \(k\), such that any solution \(\psi_k\) of problem (3.29), (3.30) satisfies the following a priori estimate

\[
\psi_k(t_k) \leq \psi_k(0) \exp\left( -\frac{d_0}{2} \gamma \omega(s_k) \right) \quad \forall k > \bar{k}(\varepsilon_0, \nu_0),
\]  

(3.32)

for some \(\bar{k} \leq t_k\), where \(t_k\) is defined by (3.31).

**Proof.** Let us assume that (3.32) is not true, and for any \(\gamma > 0\) there exist \(k \geq k_0\) such that

\[
\psi_k(t) > \frac{d_0}{2} s_k^{-2} \psi_k(t) - \tau s_k^{-2} \gamma g(s_k) \quad \forall t : 0 < t < \gamma \omega(s_k) \equiv t_k.
\]  

(3.33)

This relation combined with (3.29) implies the following inequality,

\[
\psi_k'(t) + \frac{d_0}{2} s_k^{-2} \psi_k(t) \leq 0 \quad \forall t : 0 < t \leq \gamma \omega(s_k).
\]

Solving this O.D.I. and using (3.30), we get

\[
\psi_k(t) \leq \psi_k(0) \exp \left( -\frac{d_0}{2} s_k^{-2} \frac{2}{\gamma} \right) \leq M_k \exp \left( -\frac{d_0}{2} s_k^{-2} \right) \quad \forall t \leq \gamma \omega(s_k).
\]  

(3.34)

We derive easily the next estimate from (3.34) and (3.33)

\[
M_k \exp \left( -\frac{d_0}{2} \gamma \omega(s_k) \right) \geq 2 \frac{d_0}{2} s_k^{-2} \gamma \omega(s_k).
\]  

(3.35)
Using (3.16) and (3.4), we deduce from this last inequality,

\[(1 - \varepsilon_0) \exp k \geq \frac{d_0 \gamma s_k}{2s_k} + \ln(2d_0^{-1}c^2) - \ln(\omega(s_k)^{-1}). \quad (3.36)\]

Similarly to (3.20), it follows, from (3.19) and the definition (3.16) of \(s_k\), that there holds

\[\frac{\omega(s_k) 2(1 + \nu_0)}{s_k (p - 1)} \geq \varepsilon_0 \exp k. \quad (3.37)\]

Using this estimate and (3.36), we derive

\[(1 - \varepsilon_0) \exp k \geq \frac{d_0 \gamma (p - 1) \varepsilon_0}{4(1 + \nu_0)} \exp k + \ln(d_0^{-1}c^2) - \ln(\omega(s_k))^{-1}. \quad (3.38)\]

Noticing that (3.21) implies

\[\ln(\omega(s_k))^{-1} \leq (2 - \alpha_0) \ln(s_k^{-1}), \quad (3.39)\]

and (3.22) can be written under the form

\[\ln(s_k^{-1}) \leq \frac{1}{\alpha_0} \ln \left(\frac{\varepsilon_0(p - 1)}{2(1 - \nu_0)}\right) + \frac{k}{\alpha_0}, \quad (3.40)\]

we deduce the following inequality from (3.39), (3.40) and (3.38),

\[(1 - \varepsilon_0) \exp k \geq \frac{d_0 \gamma (p - 1) \varepsilon_0}{4(1 + \nu_0)} \exp k + \ln(d_0^{-1}c^2) - (2 - \alpha_0) \frac{k}{\alpha_0} \ln \left(\frac{\varepsilon_0(p - 1)}{2(1 - \nu_0)}\right). \quad (3.41)\]

If we define \(\gamma_0\) by the equality

\[1 - \varepsilon_0 = \frac{d_0 \gamma (p - 1) \varepsilon_0}{8(1 + \nu_0)} \Rightarrow \gamma = \frac{(1 - \varepsilon_0)(1 + \nu_0)8}{d_0(p - 1)\varepsilon_0} := \gamma_0, \quad (3.42)\]

then inequality (3.41) yields to

\[\frac{2 - \alpha_0}{\alpha_0} k \geq (1 - \varepsilon_0) \exp k + \ln(2d_0^{-1}c^2) - (2 - \alpha_0) \frac{\ln \left(\frac{\varepsilon_0(p - 1)}{2(1 - \nu_0)}\right)}{\alpha_0}. \]

It is clear that we can find \(\overline{\gamma} = \overline{\gamma}(\varepsilon_0, \nu_0) < \infty\) such that the last inequality becomes impossible for \(k \geq \overline{\gamma}\), contradiction. Consequently, (3.33) does not hold for \(\gamma = \gamma_0\) and estimate (3.32) is true with \(\gamma = \gamma_0\). \(\square\)

**Proof of Theorem 3.1.** Comparing definition (3.11) of \(E(s, t)\) and definition of \(\psi_k\), we easily see that

\[E(s_k, t) \leq \psi_k(t) \Rightarrow E(s_k, \overline{t}_k) \leq \psi_k(\overline{t}_k). \quad (3.43)\]

Therefore, using estimates (3.12), (3.32) and (3.43), we obtain

\[\int_{R^N} |u_k(x, \overline{t}_k)|^2 dx = E(s_k, \overline{t}_k) + J(s_k, \overline{t}_k) \leq (d_0^{-1}c^2 + c)\overline{t}_kg(s_k). \quad (3.44)\]
Next we estimate the right-hand side of (3.44). Using (3.16), (3.31) and inequality (3.32), we get
\[
\gamma_0 \omega(s_k) M_k^o \leq \gamma_0 \omega(s_0) \exp(\varepsilon_0 \exp k), \tag{3.45}
\]
where \(\gamma_0\) is defined by (3.42) and \(s_0 > 0\) by (3.8). We obtain easily from (3.45)
\[
(\tau d_0^{-1} + c) t_k g(s_k) \leq \exp \left[ \left( \varepsilon_0 + \frac{\ln(\gamma_0 \omega(s_0)(c + \tau d_0^{-1}))}{\exp k} \right) \exp k \right]. \tag{3.46}
\]
Let \(k_1\) be the smallest integer such that
\[
\ln \left( \gamma_0 \omega(s_0)(c + \tau d_0^{-1}) \right) \leq \varepsilon_0 \exp k_1, \tag{3.47}
\]
equivalently
\[
k_1 = \left[ \ln \left( \varepsilon_0^{-1} \ln \left( \gamma_0 \omega(s_0)(c + \tau d_0^{-1}) \right) \right) \right] + 1,
\]
where \([a]\) denote integer part of \(a\). Then it follows from (3.46)
\[
(\tau d_0^{-1} + c) t_k g(s_k) \leq \exp(2\varepsilon_0 \exp k) \quad \forall k > k_1. \tag{3.48}
\]
If we fix \(\varepsilon_0\) such that
\[
2\varepsilon_0 \leq e^{-1}, \tag{3.49}
\]
then the next estimate follows from (3.44) and (3.45)–(3.49)
\[
\int_{\mathbb{R}^N} |u_k(x, \tau_k)|^2 dx \leq M_{k-1}, \tag{3.50}
\]
for all \(k \geq \max\{k_0, k_1\}\), where \(k_0\) is from (3.17), \(k_1\) from (3.47). Estimate (3.50) is the final step of the first round of computations. For the second round, we begin by defining \(s_{k-1}\) analogously to \(s_k\):
\[
g(s_{k-1}) = M_{k-1}^o = \exp(\varepsilon_0 \exp(k-1)). \tag{3.51}
\]
From estimate (3.12), we obtain
\[
J(s_{k-1}, t) + I(s_{k-1}, t) \leq ct g(s_{k-1}), \tag{3.52}
\]
since \(s_{k-1} > s_k\). Analogously to \(\varphi_k\), we define the function \(\varphi_{k-1}\) and set
\[
\psi_{k-1}(t) := \int_{\mathbb{R}^N} |u_k(x, t)|^2 |\varphi_{k-1}(x)|^2 dx.
\]
In the same way as (3.28), the following O.D.I. follows
\[
\psi_{k-1}'(t) + d_0 s_{k-2}^{-2} \psi_{k-1}(t) \leq \tau s_{k-2}^{-2} t g(s_{k-1}) \quad \forall t > \tau_k. \tag{3.53}
\]
Using (3.50), we derive
\[
\psi_{k-1}(\tau_k) \leq M_{k-1}, \quad \tau_k \leq t_k. \tag{3.54}
\]
If we analyze the Cauchy problem (3.53)–(3.54) similarly as problem (3.28)–(3.30) was analyzed in Lemma 3.3, we obtain the following \textit{a priori} estimate for \(\psi_{k-1}(t)\),
\[
\psi_{k-1}(\tau_k + \tau_{k-1}) \leq 2d_0^{-1} \tau(\tau_k + \tau_{k-1}) g(s_{k-1}), \tag{3.55}
\]
where \( t_{k-1} \leq t_k := \gamma_0 \omega(s_{k-1}) \) and \( \gamma_0 \) is defined in (3.42). It is clear that

\[
E(s_{k-1}, t) \leq \psi_{k-1}(t) \quad \forall t \geq \bar{t}_k,
\]

consequently

\[
E(s_{k-1}, \bar{t}_k + \bar{t}_{k-1}) \leq \psi_{k-1} (\bar{t}_k + \bar{t}_{k-1}) \leq 2d_0^{-1} (\bar{t}_k + \bar{t}_{k-1}) g(s_{k-1}).
\]  \(\text{(3.56)}\)

From (3.52), we deduce

\[
J(s_{k-1}, \bar{t}_k + \bar{t}_{k-1}) + I(s_{k-1}, \bar{t}_k + \bar{t}_{k-1}) \leq c(\bar{t}_k + \bar{t}_{k-1}) g(s_{k-1}).
\]  \(\text{(3.57)}\)

Summing estimates (3.56) and (3.57) we obtain

\[
\int_{\mathbb{R}^N} |u_k(x, \bar{t}_k + \bar{t}_{k-1})|^2 \, dx \leq (\bar{t}_k + \bar{t}_{k-1}) g(s_{k-1}).
\]  \(\text{(3.58)}\)

and we use this last estimate for performing a similar third round of computations. Iterating this process \( j \) times, we deduce

\[
\int_{\mathbb{R}^N} \left| u_k \left( x, \sum_{i=k}^{k-j} \bar{t}_i \right) \right|^2 \, dx \leq (\bar{t}_0 + c) \left( \sum_{i=k}^{k-j} \bar{t}_i \right) g(s_{k-j}).
\]  \(\text{(3.59)}\)

In particular, we can take \( j = k - l \), where \( l \in \mathbb{N} \) satisfies

\[
l \geq l_0 := \max\{k_0, \bar{t}, k_1\}.
\]  \(\text{(3.60)}\)

Then we obtain:

\[
\int_{\mathbb{R}^N} \left| u_k \left( x, \sum_{i=k}^{l} \bar{t}_i \right) \right|^2 \, dx \leq (\bar{t}_0 + c) \left( \sum_{i=k}^{l} \bar{t}_i \right) g(s_l).
\]  \(\text{(3.61)}\)

Next, we have to estimate from above the sum of the \( \bar{t}_i \) for which there holds

\[
\sum_{i=k}^{l} \bar{t}_i \leq \sum_{i=k}^{l} \gamma_0 \omega(s_i),
\]  \(\text{(3.62)}\)

where \( s_i \) is defined by \( g(s_i) = M_i^{\gamma_0} \). By the same way as in (3.37), we obtain

\[
s_i^2 \leq \frac{2(1 + \nu_0) \omega(s_i)}{(p - 1) \varepsilon_0} \exp(-i) \leq \frac{2(1 + \nu_0) \omega(s_0)}{(p - 1) \varepsilon_0} \exp(-i) \quad \forall i \geq l_0,
\]

where \( l_0 \) is the integer appearing in (3.60), and from this inequality follows

\[
s_i \leq \left( \frac{2(1 + \nu_0) \omega(s_0)}{(p - 1) \varepsilon_0} \right)^{1/2} \exp \left( -\frac{i}{2} \right) := C_1 \exp \left( -\frac{i}{2} \right).
\]  \(\text{(3.63)}\)

Therefore, using the monotonicity of the function \( \omega \), we derive

\[
\sum_{i=k}^{l} \omega(s_i) \leq \sum_{i=k}^{l} \omega \left( C_1 \exp \left( -\frac{i}{2} \right) \right) \leq \int_{k}^{l-1} \omega \left( C_1 \exp \left( -\frac{s}{2} \right) \right) \, ds
\]

\[
\leq 2 \int_{C_1 \exp(-\frac{1}{2})}^{C_1 \exp(-\frac{l-1}{2})} y^{-1} \omega(y) \, dy
\]

\[
\leq 2 \int_{C_1 \exp(-\frac{1}{2})}^{C_1 \exp(-\frac{l-1}{2})} y^{-1} \omega(y) \, dy
\]

\[
:= 2\Phi \left( C_1 \exp(-\frac{l-1}{2}) \right).
\]  \(\text{(3.64)}\)
As a consequence of (3.62) and (3.64), we get
\[ \sum_{i=k}^{l} t_i \leq \sum_{i=\infty}^{l} t_i \leq 2^{\gamma_0} \Phi \left( C_1 \exp \left( \frac{l-1}{2} \right) \right) := T_l. \] (3.65)

The Dini condition (3.7) implies that \( T_l \to 0 \) as \( l \to \infty \). Next, we deduce from (3.61) that
\[ \int_{\mathbb{R}^N} |u_k(x,T_l)|^2 dx \leq C_2 T_l \exp(\varepsilon_0 \exp^{l}). \] (3.66)

Using the fact that \( s \leq g(s) = M l^0 \) and (3.66), we derive
\[ \int_{\mathbb{R}^N} |u_k(x,T_l)|^2 dx \leq C_2 T_l \exp (e^{\varepsilon_0 \exp^{l}}). \] (3.67)

Because (3.65) implies
\[ \exp^{l} = e^{C_1^2 \left( \Phi^{-1} \left( \frac{T_l}{2^{\gamma_0}} \right) \right)^{-2}}, \] (3.68)
we get the following inequality by plugging this last relation into (3.67):
\[ \int_{\mathbb{R}^N} |u_k(x,T_l)|^2 dx \leq C_2 T_l \exp \left[ e^{2 \cdot \varepsilon_0 C_1^2 \left( \Phi^{-1} \left( \frac{T_l}{2^{\gamma_0}} \right) \right)^{-2}} \right] \forall l \geq l_0. \]

At last, combining last estimate with (3.68), we obtain
\[ \int_{\mathbb{R}^N} |u_k(x,t)|^2 dx \leq C_1 t \exp \left[ e^{2 \cdot \varepsilon_0 C_1^2 \left( \Phi^{-1} \left( \frac{T_l}{2^{\gamma_0}} \right) \right)^{-2}} \right] \forall t > 0, \]
which ends the proof. \( \square \)

**Example 3.4** Assume \( \omega(s) = s^{2-\alpha_0} \), \( 0 < \alpha_0 < 2 \). Then
\[ \Phi(s) = \int_{0}^{s} s^{1-\alpha_0} ds = \frac{s^{2-\alpha_0}}{2-\alpha_0} \Rightarrow \Phi^{-1}(s) = (2-\alpha) \frac{s^{2-\alpha_0}}{s^{2-\alpha_0} - \alpha_0}. \]

Consequently, estimate (3.9) reads as follows,
\[ \int_{\mathbb{R}^N} |u_k(x,t)|^2 dx \leq C_1 t \exp \left[ C_2 \left( \frac{C_3}{2-\alpha_0} \right)^{-\frac{2-\alpha_0}{2-\alpha_0}} t^{-\frac{2}{2-\alpha_0}} \right] \forall t > 0. \]

### 4 Razor blades

In this section we consider potential \( h(|x|) \) of the form \( e^{-\ell(x)} \) as in (3.6) and equation (1.1) is written under the form
\[ \partial_t u - \Delta u + e^{-\ell(|x|)} |u|^{p-1} u = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty), \] (4.1)

where \( \ell \in C(\mathbb{R}^N) \) is positive, nonincreasing and \( \lim_{r \to 0} \ell(r) = \infty \). Our main result is the following
Theorem 4.1 Assume $p > 1$ and $\ell$ satisfies
\[ \lim \inf_{x \to 0} |x|^2 \ell(x) > 0. \] (4.2)

Then the solution $u_k$ of the problem (1.1), (1.3), exists for any $k > 0$ and $u_\infty := \lim_{k \to \infty} u_k$ is a solution of (4.1) in $Q_\infty \setminus \{0\} \times \mathbb{R}^+$ with the following properties,
\[ \lim_{t \to 0} u_\infty(x, t) = 0 \quad \forall x \neq 0 \quad \text{and} \quad \lim_{x \to 0} u_\infty(x, t) = \infty \quad \forall t > 0. \] (4.3)

Furthermore $t \mapsto u_\infty(x, t)$ is increasing and $\lim_{t \to \infty} u_\infty(x, t) = U(x)$ for every $x \neq 0$ where $U = \lim_{k \to \infty} U_k$ and $U_k$ solves
\[ -\Delta U_k + e^{-\ell(x)}U_k^p = k\delta_0 \quad \text{in} \ D'(\mathbb{R}^N). \] (4.4)

Proof. By assumption (4.2), property (1.2) is fulfilled. Thus for $k > 0$ there exists $u := u_k$ solution of (4.1), (1.3). Moreover, for any $k > 0$ there exists a solution $U_k$ of (4.4) (see [18]); the mapping $k \mapsto U_k$ is increasing and $U = \lim_{k \to \infty} U_k$ exists, because of Keller-Osserman estimate. $U$ is the minimal solution of
\[ -\Delta V + e^{-\ell(x)}V^p = 0 \quad \text{in} \ \mathbb{R}^N \setminus \{0\}, \] (4.5)

verifying
\[ \int_{B_\epsilon} V(x)dx = \infty \quad \forall \epsilon > 0. \] (4.6)

If we denote by $\bar{U}$ the maximal solution of (4.5), it is classical that $\bar{U} = \lim_{\epsilon \to 0} \bar{U}_\epsilon$ where
\[ \begin{cases} 
-\Delta \bar{U}_\epsilon + e^{-\ell(x)}\bar{U}_\epsilon^p = 0 & \text{in} \ \mathbb{R}^N \setminus \bar{B}_\epsilon \\
\lim_{|x| \to 1} \bar{U}_\epsilon(x) = \infty.
\end{cases} \] (4.7)

Since any $u_k$ is bounded from above by $\bar{U}$, the local equicontinuity of the $u_k$ in $\bar{Q}_T \setminus \{0, 0\}$ implies that $u_\infty$ satisfies $\lim_{\epsilon \to 0} u_\infty(x, t) = 0$ for all $x \neq 0$.

Step 1: Formation of the razor blade. The Case 1: $1 < p < 1 + 2/N$. For $\epsilon > 0$, $e^{-\ell(|x|)} \leq e^{-\ell(\epsilon)}$ for $|x| \leq \epsilon$. Therefore
\[ \partial_t u - \Delta u + e^{-\ell(\epsilon)}|u|^{p-1}u \geq 0, \quad \text{in} \ B_\epsilon \times (0, \infty). \] (4.8)

and $u \geq v_\epsilon$ in $B_\epsilon \times (0, T)$ where $v_\epsilon$ solves
\[ \begin{cases} 
\partial_t v_\epsilon - \Delta v_\epsilon + e^{-\ell(\epsilon)}|v_\epsilon|^{p-1}v_\epsilon = 0 & \text{in} \ B_\epsilon \times (0, \infty) \\
v_\epsilon = 0 & \text{in} \ \partial B_\epsilon \times (0, \infty) \\
v_\epsilon(x, 0) = \infty \delta_0 & \text{in} \ B_\epsilon,
\end{cases} \] (4.9)

where the initial condition is to be understood in the sense $\lim_{k \to \infty} k\delta_0$. We put
\[ w_\epsilon(x, t) = \epsilon^{2/(p-1)}e^{-\ell(\epsilon)/(p-1)}v_\epsilon(\epsilon x, \epsilon^2 t). \]

Then $w_\epsilon = w$ is independent of $\epsilon$ and solves
\[ \begin{cases} 
\partial_t w - \Delta w + |w|^{p-1}w = 0 & \text{in} \ B_1 \times (0, \infty) \\
w = 0 & \text{in} \ \partial B_1 \times (0, \infty) \\
w(x, 0) = \infty \delta_0 & \text{in} \ B_1. \end{cases} \] (4.10)
Therefore
\[ u(0, 1) \geq v_\epsilon(0, 1) = e^{-2/(p-1)}\ell(x)/(p-1)w(0, e^{-2}). \] (4.11)

The longtime behaviour is given in [7] where it is proved
\[ \lim_{\tau \to \infty} e^{\lambda_1 \tau} w(0, \tau) = \kappa \phi_1(0). \]

In this formula \( \phi_1 \) is the first eigenfunction of \(-\Delta \) in \( W_{0, 1}^1(B_1) \), \( \lambda_1 \) the corresponding eigenvalue and \( \kappa > 0 \). Thus
\[ u(0, 1) \geq \delta\epsilon^{-2/(p-1)}\ell(x)/(p-1)e^{\lambda_1 e^{-2}}\phi_1(0), \] (4.12)
for some \( \delta > 0 \), if \( \epsilon \) is small enough. If we assume
\[ \lim_{\epsilon \to 0} \left( \frac{2}{p-1} \ln \epsilon^{-1} + \frac{\ell(x)}{p-1} - \lambda_1 e^{-2} \right) = \infty, \] (4.13)

it implies
\[ u(0, 1) = \infty \Rightarrow u(0, t) = \infty \quad \forall t > 0. \] (4.14)

Moreover, the unit ball \( B_1 \) can be replaced by any ball \( B_R \) and \( \lambda_1 \) by \( \lambda_R = R^{-2}\lambda_1 \). Therefore the sufficient condition for a Razor blade is that it exists some \( c > 0 \) such that
\[ \lim_{\epsilon \to 0} \left( \ell(x) - ce^{-2} \right) = \infty. \] (4.15)

An equivalent condition is
\[ \lim_{\epsilon \to 0} \epsilon^2 \ell(x) > 0. \] (4.16)

The general case. If \( p > 1 \) is arbitrary, we consider \( \beta > 0 \) such that \( \beta > N(p-1) - 2 \), and we write
\[ e^{-\ell(x)} = |x|^\beta e^{-\ell(x) - \beta \ln |x|}. \]

For \( R > 0 \) small enough \( x \mapsto \ell(x) := \ell(x) + \beta \ln |x| \) is positive, increasing and satisfies the same blow-up condition (4.2) as \( \ell \). Clearly \( u_k \) is bounded from below on \( B_R \times (0, \infty) \) by the solution \( \tilde{u} := \tilde{u}_k \) of
\[ \begin{cases} 
\partial_t \tilde{u} - \Delta \tilde{u} + |x|^\beta e^{-\ell(x)} |\tilde{u}|^{p-1} \tilde{u} = 0 & \text{in } B_R \times (0, \infty) \\
\tilde{u} = 0 & \text{on } \partial B_R \times (0, \infty) \\
\tilde{u}(x, 0) = k\delta_0 & \text{in } B_R. 
\end{cases} \] (4.17)

Therefore, for \( 0 < \epsilon < R \), \( \tilde{u}_\infty \) is bounded from below on \( B_\epsilon \times (0, \infty) \) by the solution \( v_\epsilon \) of
\[ \begin{cases} 
\partial_t v_\epsilon - \Delta v_\epsilon + |x|^\beta e^{-\ell(x)} |v_\epsilon|^{p-1} v_\epsilon = 0 & \text{in } B_\epsilon \times (0, \infty) \\
v_\epsilon = 0 & \text{on } \partial B_\epsilon \times (0, \infty) \\
v_\epsilon(x, 0) = \infty \delta_0 & \text{in } B_\epsilon. 
\end{cases} \] (4.18)

If we set
\[ w_\epsilon(x, t) = \epsilon^{2+\beta}/(p-1)e^{-\ell(x)}/(p-1)v_\epsilon(\epsilon x, \epsilon^2 t), \]
then \( w_\epsilon = w \) is independent of \( \epsilon \) and
\[ \begin{cases} 
\partial_t w - \Delta w + |x|^\beta |w|^{p-1} w = 0 & \text{in } B_1 \times (0, \infty) \\
w = 0 & \text{on } \partial B_1 \times (0, \infty) \\
w(x, 0) = \infty \delta_0 & \text{in } B_1. 
\end{cases} \] (4.19)
By a straightforward adaptation of the result of [7], there still holds
\[ \lim_{\tau \to \infty} e^{\lambda_\tau} w(0, \tau) = \kappa \phi_1(0) \]
for some \( \kappa > 0 \). The remaining of the proof is the same as in case 1 \( p < 1 + 2/N \).

**Step 2: Asymptotic behaviour.** A key observation is that, for any \( \tau > 0 \) and any \( \epsilon_0 > 0 \)
\[ \int_{\mathbb{R}^N} u_{\infty}(x, \tau) dx = \infty. \] (4.20)
We give the proof in the case \( 1 < p < 1 + 2/N \), the general case being similar. By step 1
\[ \int_{B_1} u(x, \tau) dx \geq \int_{B_1} v(x, \tau) dx = e^{-2/(p-1)} e^{e^{\lambda_\tau}/(p-1)} \int_{B_1} w(y, \epsilon^{-2}) dy. \] (4.21)
If we fix \( \tau \) and use [7], there exists \( \epsilon_0 \) such that \( w(y, \epsilon^{-2}) \geq 2^{-1} \kappa \epsilon^{-\lambda_1 \epsilon^{-2}} \phi_1(y) \) for \( \epsilon \leq \epsilon_0 \) and
\( y_1 \in B_1 \). Therefore
\[ \int_{B_1} u(x, \tau) dx \geq c \epsilon^{-2/(p-1)} e^{e^{\lambda_\tau}/(p-1) - \lambda_1 \epsilon^{-2}}, \] (4.22)
for some constant \( c > 0 \). If \( \tau \) is small enough, the right-hand side of (4.22) tends to infinity as \( \epsilon \to 0 \), so does the left-hand side. This implies (4.20). For any \( k > 0 \) and any \( \epsilon > 0 \), there exists \( m = m(\epsilon) > 0 \) such that
\[ \int_{B_1} \min\{u(x, \tau), m\} dx = k, \]
thus, if we set \( \phi_m = \min\{u(x, \tau), m\} \chi_{B_1} \), then \( u \) is bounded from below on \( \mathbb{R}^N \times (\tau, \infty) \) by
\[ \begin{cases} 
\partial_t v - \Delta v + e^{-\ell(x)} e^{\lambda_{\tau} - 1} v = 0 & \text{in } \mathbb{R}^N \times (\tau, \infty) \\
v(x, \tau) = \phi_m(x) & \text{in } \mathbb{R}^N. 
\end{cases} \] (4.23)
When \( \epsilon \to 0 \), \( \phi_m(\cdot) \to k \delta_0 \) weakly in \( \mathcal{M}(\mathbb{R}^N) \). By standard approximation property, \( v(\epsilon, k) \to v_0, \)
which is a solution of
\[ \begin{cases} 
\partial_t v - \Delta v + e^{-\ell(x)} e^{\lambda_{\tau}} e^{\lambda_{\tau} - 1} v = 0 & \text{in } \mathbb{R}^N \times (\tau, \infty) \\
v(\cdot, \tau) = k \delta_0 & \text{in } \mathbb{R}^N. 
\end{cases} \] (4.24)
By uniqueness, \( v_{0,k}(x, t) = u_k(x, t - \tau) \). Letting \( k \to \infty \) yields to
\[ u_{\infty}(x, t + \tau) \geq u_{\infty}(x, t) \quad \forall (x, t) \in Q_T. \] (4.25)
This implies that \( t \mapsto u_{\infty}(x, t) \) is increasing for every \( x \in \mathbb{R}^N \). Because \( u(x, t) \leq U(x) \), it is straightforward that \( \lim_{t \to \infty} u(x, t) = U(x) \) exists in \( \mathbb{R}^N \setminus \{0\} \).

**Step 3: Identification of the limit.** If \( \zeta \in C_0^\infty(\mathbb{R}^N \setminus \{0\}) \), there holds
\[ \int_{Q_T} \int_{\mathbb{R}^N} \left( -u(x, t) \Delta \zeta(x) + e^{-\ell(x)} u^p(x, t) \zeta(x) \right) dx dt = \int_{\mathbb{R}^N} \left( u(x, T) - u(x, T + 1) \right) \zeta(x) dx. \]
By Lebesgue’s theorem
\[ \int_{\mathbb{R}^N} \left( -\tilde{U}(x) \Delta \zeta(x) + e^{-\ell(x)} \tilde{U}^p(x) \zeta(x) \right) dx = 0, \] (4.26)
and, from (4.20),
\[ \int_{\epsilon_0} \tilde{U}(x)dx = \infty, \] (4.27)

for any \( \epsilon_0 > 0 \). Therefore \( \tilde{U} \) is a solution of the stationary equation (4.4) in \( \mathbb{R}^N \setminus \{0\} \) with a strong singularity at 0. For \( k > 0 \) and \( \epsilon > 0 \) there exists \( k(\epsilon) > 0 \) such that
\[ \int_{B_\epsilon} U_{k(\epsilon)} dx = k. \]

Let \( v := v_{k,\epsilon} \) be the solution of
\[ \begin{cases} 
\partial_t v - \Delta v + e^{-\ell(x)|v|^{p-1}v = 0 & \text{in } Q_T, \\
v(.,0) = U_{k(\epsilon)} \chi_{B_\epsilon} & \text{in } \mathbb{R}^N.
\end{cases} \] (4.28)

Since \( v_{k,\epsilon}(.,0) \leq U_{k(\epsilon)}(.) \), the maximum principle implies \( v_{k,\epsilon} \leq U_{k(\epsilon)} \). If we let \( \epsilon \to 0 \), \( v_{k,\epsilon} \) converges to the solution \( u_k \) with initial data \( k \delta_0 \). Furthermore \( k(\epsilon) \to \infty \) as \( \epsilon \to 0 \). Therefore
\[ u_k(x,t) \leq U(x) \quad \forall (x,t) \in Q_T. \] (4.29)

Letting successively \( k \to \infty \) and \( t \to \infty \) implies
\[ \tilde{U}(x) \leq U(x) \quad \forall x \in \mathbb{R}^N. \] (4.30)

Since \( U \) is the minimal solution of (4.5) verifying (4.6), it follows that \( U = \tilde{U} \).
