We explore the unitarity violation of the CKM matrix in the model in which the third generation fermions are subjected to the separate SU(2)L gauge interaction. With the recent LEP and SLC data at Z-pole and low-energy neutral current interaction data, the analysis on the parameter space of the model is updated, and the unitary violation is predicted under the constraint.

I. INTRODUCTION

The Cabibbo-Kobayashi-Maskawa (CKM) matrix describes quark mixings for the charged current interaction. Each element of the CKM matrix is not determined theoretically but just parametrized by three angles and one phase due to the unitarity nature of the CKM matrix in the framework of the Standard Model (SM). The unitarity of the CKM matrix is a universal feature of the flavour physics and also holds in many new physics scenarios like the minimal supersymmetric standard model (MSSM) as well as in the SM. We parametrize the unitarity relation for the first row of the matrix as

\[ |V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 - \Delta, \]

and \( \Delta \) should be zero in the SM. Experimentally each element has been measured through various weak interaction processes. Recently the precision test on the CKM matrix becomes possible and the unitarity check on the first row of the CKM matrix has been performed \(^1\). From the recent nuclear \( \beta \)-decay data, the first element is determined that \( |V_{ud}| = 0.9740 \pm 0.0005 \). Combined with \( |V_{us}| = 0.2196 \pm 0.0023 \) from kaon decays and \( |V_{ub}| = 0.0036 \pm 0.0009 \) from \( B \) decays, it leads to \( \Delta = 0.0031 \pm 0.0014 \), which indicates a violation of the unitarity by 2.2 \( \sigma \) standard deviation \(^2\). However, recent experimental results on \( |V_{us}| \) suggests unitarity again with good precision \(^3\).

If the violation of the unitarity relation in the CKM matrix turns out to be true, it is a clear evidence of the new physics beyond the SM. It suggests an interesting constraint for the nature of the possible new physics since the conventional supersymmetric models and GUT models usually preserve the unitarity of the CKM matrix. Examples of model with nonunitary CKM matrix contains the model with a heavy singlet quark where the mixing between the singlet quark and ordinary quarks can violate unitarity. Another example is the model with fourth generation, where the \( 4 \times 4 \) quark mixing matrix is unitary while \( 3 \times 3 \) mixing matrix is not.

The nonuniversal gauge interaction is also a possible candidate leading to the non-unitarity of the CKM matrix. The mass matrices of up-type and down-type quarks are diagonalized by a biunitary transformation with two independent unitary matrices. The charged current interactions in terms of physical states are expressed by the product of the two unitary transform matrices for left-handed up-type quarks and down-type quarks, which should be unitary since the mixing matrix is the product of two unitary matrices in the SM. However, if the SU(2) gauge interaction is nonuniversal, the mixing matrix consists of

\[ V_{CKM} = V_U^\dagger \begin{pmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & c \end{pmatrix} V_D, \]

which is no more unitary unless \( a = b = c \). We consider a model which contains a nonuniversal gauge interaction to predict a non-unitary CKM matrix in this work.

The flavour physics on the third generation has drawn much interest as a laboratory where new physics manifests. The forward-backward asymmetry for the \( Z \to b \bar{b} \) process still shows more than 2-\( \sigma \) deviation from the SM prediction and the large value of top quark mass may imply a new dynamics. Thus we consider the model where a separate SU(2) group acts only on the third generation while the first two generations couple to the usual SU(2) group

∗Electronic address: kylee@muon.kaist.ac.kr
This gauge group can arise as the theory at an intermediate scale in the path of gauge symmetry breaking of noncommuting extended technicolor (ETC) models in which the gauge groups for extended technicolor and for the weak interactions do not commute. Due to the nonuniversality of the gauge couplings, the CKM matrix is not unitary in this model, although the unitarity violation is suppressed by the heavy scale of new physics. Moreover the flavour-changing neutral current (FCNC) interactions generically emerge in this model, since the neutral currents are no more simultaneously diagonalized with the corresponding mass matrix. Together with a new spectrum of gauge bosons, the FCNC interactions predict various new phenomena at colliders and low-energy experiments, and highly constrain the model parameters. The phenomenology of this model has been intensively studied in the literatures, using the Z-pole data and the low-energy data.

In this work, we estimate the unitarity violation in the proposed model and show that the unitarity violation data can be explained in this model constrained under the $Z \rightarrow bb$ process at the Z-pole and low-energy neutral current experiments. We update the previous analysis in Ref. [7] with the recent LEP and SLC data [10]. The atomic parity violation (APV), the neutrino-nucleon scattering, $ve \rightarrow ve$ scattering and polarized $e-N$ scattering data are also considered to constrain the model parameters describing the new physics scale and $Z-Z'$ mixing. The observable quantity in the SM is the only product of the unitary transform matrices for the left-handed up-type and down-type quarks. However in this model, the matrix elements of the individual unitary transform matrices manifest in some processes involving the third generation and we might confront doubled parameters on the quark mixing. Thus we have to be careful in treating new parameters.

This paper is organized as follows: In section 2, we briefly review the model with a separate SU(2) symmetry for the third generation and show the unitarity violation in this model. The Z-pole data in the LEP and SLC experiments and low-energy neutral current interaction experiments are analyzed to constrain the parameter space of the model in section 3. The unitarity violating term is predicted under the constraints in section 4 and we conclude in section 5.

II. THE MODEL

We consider the model based on the extended electroweak gauge group $SU(2)_l \times SU(2)_h \times U(1)_Y$. The first and the second generations couple to $SU(2)_l$ group and the third generation couples to $SU(2)_h$ group. We assign that the left-handed quarks and leptons of the first and second generations transform as $(2,1,1/3)$, $(2,1,-1)$ and those in the third generation transform as $(1,1,2)$. $Z$ can be explained in this model constrained under the $\nu_e$ parity violation (APV), the neutrino-nucleon scattering, $ve \rightarrow ve$ scattering and polarized $e-N$ scattering data are also considered to constrain the model parameters describing the new physics scale and $Z-Z'$ mixing. The observable quantity in the SM is the only product of the unitary transform matrices for the left-handed up-type and down-type quarks. However in this model, the matrix elements of the individual unitary transform matrices manifest in some processes involving the third generation and we might confront doubled parameters on the quark mixing. Thus we have to be careful in treating new parameters.

This paper is organized as follows: In section 2, we briefly review the model with a separate SU(2) symmetry for the third generation and show the unitarity violation in this model. The Z-pole data in the LEP and SLC experiments and low-energy neutral current interaction experiments are analyzed to constrain the parameter space of the model in section 3. The unitarity violating term is predicted under the constraints in section 4 and we conclude in section 5.
where \( \mathcal{L}_I^g \) denotes the universal part and \( \mathcal{L}_I^{nc} \) the nonuniversal part. We consider the unitary matrices \( V_U \) and \( V_D \) diagonalizing \( U \)-type and \( D \)-type quark mass matrices respectively. The universal part is given by

\[
\mathcal{L}_I = \bar{U}_L \gamma_{\mu} \left[ G_L W^\mu + G'_L W'^{\mu} \right] (V_D^\dagger V_D) D_L + \text{H.c.} \tag{7}
\]

where

\[
G_L = -\frac{g}{\sqrt{2}} \left( 1 - \lambda \sin^4 \phi \right) I
\]

\[
G'_L = \frac{g}{\sqrt{2}} \left( \tan \phi + \lambda \sin^3 \phi \cos \phi \right) I
\]

(8)

with the 3x3 identity matrix \( I \) and \( U = (u, c, t)^T \) and \( D = (d, s, b)^T \). We define the unitary matrix \( V^g_{CKM} \equiv V_U^I V_D \) corresponding to the CKM matrix of the SM. The nonuniversal part is written in terms of mass eigenstates as:

\[
\mathcal{L}^{nc}_3 = (V_{31} \bar{u}_L + V_{32} \bar{c}_L + V_{33} \bar{t}_L) \times \gamma^\mu (X_L W^\mu + X'_L W'^\mu) (V^D_{31} d_L + V^D_{32} s_L + V^D_{33} b_L), \tag{9}
\]

where

\[
X_L = -\frac{g}{\sqrt{2}} \lambda \sin^2 \phi 
\]

\[
X'_L = -\frac{g}{\sqrt{2}} \left( \frac{1}{\sin \phi \cos \phi} \right).
\]

(10)

Because of the existence of \( \mathcal{L}_3 \), the quark mixing matrix is no more unitary. Moreover the elements of individual unitary transform matrices \( V_U \) and \( V_D \) \{\( V_{U3j}, V_{D3k} \)\} manifest in the unitarity violating term in general, which are not observable in the SM. With these elements, the number of parameters increases drastically. This property might make it be very interesting to study lots of new phenomena in this model, e.g. exotic CP violation or FCNC. However, as will be shown later, the additional parameters \( \{V_{U3j}, V_{D3k}\} \) do not play a role in the present analysis.

We can read out the expressions for the neutral current interaction terms from the interaction lagrangian. The nonuniversality of the gauge couplings brings forth the FCNC interactions at tree level which does not exist in the SM. The FCNC effects on the lepton number violating processes have been discussed in Ref. [9]. For the quark sector, the FCNC interaction terms evolve with the basis used above as follows

\[
\mathcal{L}^{nc}_3 = (V_{31} \bar{d}_L + V_{32} \bar{s}_L + V_{33} \bar{b}_L) \times \gamma^\mu (Y_L Z^0_\mu + Y'_L Z'^0_\mu) (V^D_{31} d_L + V^D_{32} s_L + V^D_{33} b_L), \tag{11}
\]

where

\[
Y_L = \frac{g}{2 \cos \theta} \cdot \lambda \sin^2 \phi 
\]

\[
Y'_L = \frac{g}{2} \cdot \frac{1}{\sin \phi \cos \phi},
\]

(12)

which yield an additional contribution to the \( B - \bar{B} \) mixings and rare decay processes through \( Z \) and \( Z' \) exchange diagrams, and have been discussed in Ref. [9]. In this paper, we assume no lepton flavour violation to concentrate on the quark mixings.

III. EXPERIMENTAL CONSTRAINTS

A. Z-pole data

We write the most general amplitude for \( Z \to b \bar{b} \) decay as

\[
M(Z \to b \bar{b}) = \frac{g}{2 \cos \theta_W} \epsilon^\mu \bar{u} \gamma_\mu (g_W - g_{bA} \gamma_5) u, \\
= \frac{g}{2 \cos \theta_W} \epsilon^\mu \bar{u} \left( \gamma_\mu (g^0_W - g^0_{bA} \gamma_5) + \Delta^k_5 \gamma_\mu P_L + \Delta^R_5 \gamma_\mu P_R \right) u, \tag{13}
\]
where $\epsilon^\mu$ is the polarization vector for $Z$ boson, $g_{bV}$ ($g_{bA}$) is the vector (axial–vector) coupling of $b$ quark pair to $Z$ boson, and $g_{bV}^0$ ($g_{bA}^0$) is the SM tree level coupling. In the SM, $\Delta_k^L$ and $\Delta_k^R$ are the electroweak corrections including the dependences on $m_t$ and $m_H$. The large mass of top quark gives rise to additional contribution of $m_t$-dependent corrections to $\Delta_k^L$ such as $\Delta_k^L(m_t^2)$, which arises from the top quark exchange diagram. It is absent in the cases of light quarks, while the contribution from these diagrams to $\Delta_k^R$ is suppressed by the factor of $m^2_t/m^2_b$.

Precise measurement of the $Z$–pole data at LEP and SLC has provided highly accurate tests on the SM [11, 12]. Still more than $-2\sigma$ deviation of $A_{FB}$, the forward–backward asymmetry of $Z \rightarrow b\bar{b}$ decay from the SM prediction suggests a hint of the departure from the SM in the list of the LEP and SLC data. It is quite helpful to introduce the precision variables for the study of the new physics effects on the electroweak data because the new physics contributions to the $Z$–pole observables are expected to be comparable with the loop contributions of the SM. Here, we use the nonstandard electroweak precision test in terms of the $\epsilon$ variables introduced by Altarelli et al. [13, 14] which is useful for the analysis of the $Z$–pole data. This $\epsilon$ analysis provides a model independent way to analyze the electroweak precision data, where the electroweak radiative corrections containing whole $m_t$ and $m_H$ dependencies are parametrized into the parameters $\epsilon$'s. Thus the $\epsilon$'s can be extracted from the data without specifying $m_t$ and $m_H$.

The universal correction terms to the electroweak form factors $\Delta_0$ and $\Delta_k$ are obtained from the mass ratio $m_w/m_Z$ by the Eq. (1) of Ref. [14]. The parameters ($\epsilon_1, \epsilon_2, \epsilon_3$) are defined by the linear combinations of correction terms as given by [13, 14]:

\[
\begin{align*}
\epsilon_1 &= \Delta_0, \\
\epsilon_2 &= \epsilon_0^2 \Delta_0 + \frac{s^2_0 \Delta_0 R_W}{\epsilon_2 - s^2_0} - 2s_0^2 \Delta_k, \\
\epsilon_3 &= \epsilon_0^2 \Delta_0 + (c_0^2 - s_0^2) \Delta_k,
\end{align*}
\]

which avoid the new physics effects being masked by the large $m^2_t$ corrections in $\epsilon_2$ and $\epsilon_3$. We note that $\Delta_0 R_W$ is irrelevant for our analysis and affects only on $\epsilon_2$. Hence we lay aside $\epsilon_2$ in this paper.

The parameter $\epsilon_3$ is introduced to measure the additional contribution to the $Zb\bar{b}$ vertex due to the large $m_t$-dependent corrections in the SM. Since the leading contribution of the electroweak radiative correction of the SM given in Eq. (13) is left-handed in the large $m_t$ limit, Altarelli et al. have defined $\epsilon_3$ through the effective couplings $g_{bA}$ and $g_{bV}$ in the following manner [14]:

\[
\begin{align*}
\epsilon_3 &= \frac{g_{bV}}{g_{bA}} = \frac{1 - \frac{4}{3}s_0^2(1 + \Delta k)}{1 + \epsilon_b}.
\end{align*}
\]

of which asymptotic contribution is given by $\epsilon_b \approx -G_F m^2_t/4\pi^2 \sqrt{2}$. The parameter $\epsilon_b$ defined in this expression is identical to $-\Delta_{0}(m^2_t)$ given in Eq. (14).

Since $\epsilon_b$ cannot be the most general expression for $Zb\bar{b}$ vertex, we have to introduce a new parameter to describe the additional right–handed current interaction effects as done in Ref. [15, 16]. We define the correction terms $\Delta_{0b}$ and $\Delta_{kb}$ in an analogous way to those of lepton sector:

\[
\begin{align*}
\Delta_{0b} &= g_{bA}(1 + \Delta_{0b}) = -\frac{1}{2} \left(1 + \frac{1}{2} \Delta_0\right) (1 + \Delta_{0b}), \\
\sin^2 \theta^l_{\text{eff}} &= \sin^2 \theta^l_{\text{eff}}(1 + \Delta_{kb}) = s^2_0(1 + \Delta k)(1 + \Delta_{kb}),
\end{align*}
\]

where $\Delta_{0b}$ is a deviation of $g_{bA}$ from the axial coupling of lepton sector $g_A$, and $\Delta_{kb}$ is introduced through the effective Weinberg angle for $b$ quark sector. To avoid being masked by the electroweak radiative corrections of the SM, we
define the new epsilon parameters by the relations
\[ \epsilon_b = \Delta \rho_b, \quad \epsilon'_b = \frac{2}{3} \epsilon_0^2 (\Delta \rho_b + \Delta k_b), \] (18)
with canceling \( \Delta^S_M(m_t^2) \) in \( \epsilon'_b \). Note that we have \( \Delta \rho_b = -\Delta k_b = -\Delta^S_M(m_t^2) \) in the SM, \( \epsilon_b \) goes to the original definition in Eq. (16) and \( \epsilon'_b = 0 \). Consequently \( \epsilon'_b \) purely measures the anomalous right-handed current interaction.

The parameters \( \epsilon_1 \) and \( \epsilon_3 \) are extracted from the inclusive partial decay width \( \Gamma_b \) and the forward-backward asymmetry \( A_{FB}^b \) and \( \epsilon_b \) and \( \epsilon'_b \) are extracted from the observables of the inclusive decay width \( \Gamma_b \) and forward-backward asymmetry of \( b\bar{b} \) production \( A_{FB}^b \). In consequence, the four parameters \( \epsilon_1, \epsilon_3, \epsilon_b, \) and \( \epsilon'_b \) are set to be one to one correspondent to the observables \( \Gamma_b, A_{FB}^b, \Gamma_b, \) and \( A_{FB}^b \). The quadratic \( m_t \) dependences of the SM electroweak radiative correction appears in \( \epsilon_1 \) and \( \epsilon_3 \) while the \( m_t \) dependence of \( \epsilon'_b \) is logarithmic.

According to the definitions, we can express the observables in terms of \( \epsilon_i \)’s up to the linear order as given in Eq. (123) of Ref. [12], which make it easy to perform the numerical analysis. We give the modification of the linearized relations by excluding the equation of \( m_W^2/m_Z^2 \) and adding the modified equations between the observables \( \Gamma_b, A_{FB}^b \) and the \( \epsilon \) parameters as
\[ \Gamma_b = \Gamma_b|_B(1 + 1.42 \epsilon_1 - 0.54 \epsilon_3 + 2.29 \epsilon_b) \]
\[ A_{FB}^b = A_{FB}|_B(1 + 17.5 \epsilon_1 - 22.75 \epsilon_3 + 0.157 \epsilon_b) \] (19)
while the relations of \( \Gamma_l \) and \( A_{FB}^l \) remains intact
\[ \Gamma_l = \Gamma_l|_B(1 + 1.20 \epsilon_1 - 0.26 \epsilon_3), \]
\[ A_{FB}^l = A_{FB}|_B(1 + 34.7 \epsilon_1 - 45.15 \epsilon_3), \]
with \( s_0^2 = 0.2311 \). The Born approximation values \( \Gamma_b|_B \) and \( A_{FB}|_B \) are defined by the tree level results including pure QED and pure QCD corrections and consequently depend upon the values of \( \alpha_s(m_Z^2) \) and \( \alpha(m_Z^2) \). The QCD corrections to the forward-backward asymmetries of \( b \) quark pair in \( Z \) decays are given in the Ref. [17, 18]. We obtain \( \Gamma_b|_B = 379.8 \text{ MeV} \), and \( A_{FB}|_B = 0.1032 \) with the values \( \alpha_s(m_Z^2) = 0.119 \) and \( \alpha(m_Z^2) = 1/128.90 \). For the experimental analysis of \( A_{FB}^b \), a bias factor has to be introduced to scale the QCD corrections. Here we used the average value, \( s_0 = 0.435 \), given in Ref. [17]. Through these four linear equations between \( \Gamma_l, A_{FB}^l, \Gamma_b, A_{FB}^b \) and \( (\epsilon_1, \epsilon_3, \epsilon_b, \epsilon'_b) \), we obtain the 4-dimensional ellipsoid in \( (\epsilon_1, \epsilon_3, \epsilon_b, \epsilon'_b) \) space from the recent LEP+SLC data given in Table I, which yields
\[ \epsilon_1 = (5.1 \pm 1.1) \times 10^{-3}, \]
\[ \epsilon_3 = (3.8 \pm 1.8) \times 10^{-3}, \]
\[ \epsilon_b = (2.8 \pm 2.9) \times 10^{-2}, \]
\[ \epsilon'_b = (3.5 \pm 4.0) \times 10^{-2}. \] (20)

We write the vector and axial vector couplings of fermions to \( Z \) boson at tree level as
\[ g_V = T_{3h} + T_{3l} - 2 Q \sin^2 \theta_W + \lambda \sin^2 \phi (T_{3h} \cos^2 \phi - T_{3l} \sin^2 \phi), \]
\[ g_A = T_{3h} + T_{3l} + \lambda \sin^2 \phi (T_{3h} \cos^2 \phi - T_{3l} \sin^2 \phi), \] (21)
where \( \sin^2 \theta_W \) is defined as the shifted Weinberg angle at tree level corrected by the new contribution
\[ \sin^2 \theta_W = s_0^2 - \lambda^4 \phi \frac{c_0^2 s_0^2}{c_0^2 - s_0^2}, \] (22)
up to the linear order of \( \lambda \). With these shifted couplings, we obtain the additional contributions to \( \epsilon \) parameters in our model,
\[ \epsilon_1^{\text{new}} = -2 \lambda \sin^4 \phi, \]
\[ \epsilon_3^{\text{new}} = - \lambda \sin^4 \phi, \]
\[ \epsilon_b^{\text{new}} = \lambda \sin^2 \phi (1 + |V_{33}^D|^2), \]
\[ \epsilon'_b^{\text{new}} = \lambda \sin^2 \phi |V_{33}^D|^2, \] (23)
which is expressed by three parameters, \( \lambda, \sin \phi \) and \( V_{33}^D \).
With the experimental ellipsoid given in Eq. (20), the allowed parameter space is given by

$$\lambda < 0.126 \ (0.14) \ \text{ at } 90\% \ (95\%) \ \text{C.L.},$$  

(24)

and \(\sin \phi\) and \(|V_{33}^D|\) are unconstrained. This bound is corresponding to \(m_{Z'} > 1.15 \ (1.10) \ \text{TeV}..\) We plot the model predictions in terms of model parameters with the experimental ellipses for 1-\(\sigma\) and 2-\(\sigma\) confidence level in Fig. 1. The left upper plot is given on the \(\epsilon_1 - \epsilon_3\) plane, the right upper plot on the \(\epsilon_1 - \epsilon_6\) plane, the left lower plot on the \(\epsilon_1 - \epsilon_b\) plane, the right lower plot on the \(\epsilon_3 - \epsilon_b\) plane. The straight lines denote the model predictions and the SM predictions is expressed by the black dots. We vary the parameter \(\sin^2 \phi\) and fix \(|V_{33}^D|\) to be 1. The parameter \(|V_{33}^D|\) far from 1 is not likely since \(|V_{bb}| \approx 1\).

### B. Low energy experiment

The low-energy neutral current interactions such as \(\nu e \rightarrow \nu e\), \(\nu N\) scattering, and \(e_{L,R}N \rightarrow e_{L,R}X\) are expressed by the effective four-fermion interactions and the coefficients of four-fermion operators have been precisely measured. The SM predictions for the coefficients are obtained including radiative corrections, while our model predictions involve the effective four-fermion interactions and the coefficients of four-fermion operators have been precisely measured. The low-energy neutral current interactions such as \(\nu e \rightarrow \nu e\) at low energy can be written in the form

$$H^{\nu e} = \frac{G_F}{\sqrt{2}} \gamma^\mu (1 - \gamma_5) \nu \bar{\nu} (1 - \gamma_5) q_i + \epsilon_{L,R}(i) \bar{\nu}_{\gamma_\mu} (1 - \gamma_5) q_i,$$  

(25)

where \(\epsilon_{L,R}(i) (i = u,d)\) are given by

$$\epsilon_{L,R}(u,d) = \epsilon_{L,R}(u,d)(1 - \lambda \sin^4 \phi).$$  

(26)

The relevant effective Hamiltonian for the scattering \(\nu e \rightarrow \nu e\) at low energy can be written in the form

$$H^{\nu e} = \frac{G_F}{\sqrt{2}} \gamma^\mu (1 - \gamma_5) \nu \bar{\nu} (1 - \gamma_5) q_i (g_V^{\nu e} - g_A^{\nu e} \gamma_5).$$  

(27)

The coupling constants \(g_V^{\nu e}\) and \(g_A^{\nu e}\) are written as

$$g_{V(A)}^{\nu e} = g_{V(A)}^{\nu e}|_{\text{SM}} (1 - \lambda \sin^4 \phi).$$  

(28)

For electron-hadron scattering such as \(e_{L,R}N \rightarrow eX\) performed in the SLAC polarized electron experiment, the parity-violating Hamiltonian can be written as

$$H^{eN} = -\frac{G_F}{\sqrt{2}} \sum_i \left[ C_{1i} \bar{q}^\mu \gamma_5 e \bar{q}^\mu (g_V^{eN} - g_A^{eN} \gamma_5) q_i + C_{2i} \bar{q}^\mu \gamma_5 e \bar{q}^\mu (g_V^{eN} - g_A^{eN} \gamma_5) q_i \right].$$  

(29)

The coefficients \(C_{1i}\) are given by

$$C_{1u,d} = C_{1u,d}^{\text{SM}} (1 - \lambda \sin^4 \phi)$$  

(30)

while the coefficients \(C_{2i}\) given by

$$C_{2u} = C_{2u}^{\text{SM}} (1 - \lambda \sin^4 \phi) + 2 \lambda |V_{31}^U|^2 \sin^2 \phi \sin^2 \theta_W,$$

$$C_{2d} = C_{2d}^{\text{SM}} (1 - \lambda \sin^4 \phi) - 2 \lambda |V_{31}^D|^2 \sin^2 \phi \sin^2 \theta_W.$$  

(31)

Note that only \(C_{2i}\) involve the additional parameters \(V_{31}^{U,D}\) because of the operator structure.

The experimental values for the observables and the standard model predictions are tabulated in Table II referring to the particle data book \[19\]. We perform the \(\chi^2\) fit for the ten physical observables listed in Table II with respect to the parameters \(\lambda, \sin \phi\) and \(|V_{3j}^{U,D}|\). The best fit value is obtained at

$$\lambda = 0.435, \ \sin \phi = 0.25, \ |V_{33}^U| = 0.7, \ |V_{33}^D| = 0, \ m_{Z'} = 503.76 \ (\text{GeV}),$$  

(32)

with \(\chi^2/dof = 11.331/10\). Under the LEP bound of Eq. (26), the best fit values are

$$\lambda = 0.112, \ \sin \phi = 0.35, \ |V_{33}^U| = 1, \ |V_{33}^D| = 0, \ m_{Z'} = 732.99 \ (\text{GeV}),$$  

(33)
with $\chi^2/dof = 11.332/10$. We note that the $\chi^2_{\text{min}}$ is very close to the SM value $\chi^2_{\text{SM}}/dof = 11.35/10$ and no absolute bound for $\lambda$ and $\sin \phi$ from the low-energy data.

The atomic parity violation can be described by the Hamiltonian in Eq. (24). The weak charge of an atom is defined as

$$Q_W = -2 \left[ C_{1u}(2Z + N) + C_{1d}(Z + 2N) \right],$$

(34)

where $Z$ ($N$) is the number of protons (neutrons) in the atom. For $^{133}\text{Cs}$ atom, $Z = 55$, $N = 78$, the correction to the weak charge is given by

$$\Delta Q_W = Q_W - Q_W^{\text{SM}} = -2 \left[ \Delta C_{1u}(2Z + N) + \Delta C_{1d}(Z + 2N) \right]$$

$$= \Delta Q_W^{\text{SM}} (1 - \lambda \sin^4 \phi).$$

(35)

The recent measurements and the analyses of the weak charge for the Cs and Tl atoms give the value $^{[20]}$.

$$Q_W = -72.69 \pm 0.48 \quad (\text{Cs}),$$

$$Q_W = -116.6 \pm 3.7 \quad (\text{Tl}),$$

(36)

while the SM predictions are $Q_W = -73.19 \pm 0.03 \ (\text{Cs})$, and $Q_W = -116.81 \pm 0.04 \ (\text{Tl})$. The bound from Cs atom is stronger than that from Tl atom. Figure 2 shows the allowed region of the parameter space $(\lambda, \sin^2 \phi)$ by the low-energy neutral current data and the atomic parity violation data at 90 % confidence level. We find that the constraint of the atomic parity violation is stronger than that of the $\chi^2$ fit of the low-energy neutral current data.

IV. UNITARITY VIOLATION

We have the modified CKM matrix in the lagrangian:

$$V_{\text{CKM}} = V_{\text{CKM}}^0 + \begin{pmatrix}
V_{U31}^U & V_{U32}^U & V_{U33}^U \\
V_{D31}^D & V_{D32}^D & V_{D33}^D \\
V_{\lambda}^U & V_{\lambda}^D & V_{\lambda}^D
\end{pmatrix} \cdot \lambda \sin^2 \phi,$$

(37)

which describes the quark mixings for the charged currents coupled to the $W^\pm\text{bosons}$. The mixing matrix for $W'^\pm\text{bosons}$ has the same structure as above matrix except that the model parameter $\lambda \sin^2 \phi$ is replaced by $1/\sin \phi \cos \phi$.

Although the quark mixing matrix is given in Eq. (37), the ‘observed’ CKM matrix measures the effective charged current interactions through both $W$ and $W'$ exchange diagrams at low energies. We consider the effective Hamiltonian for extracting $|V_{uj}|$

$$\mathcal{H}_{\text{eff}} = \frac{G_F}{\sqrt{2}} \sum_{q=d,s,b} V_{uj} (\bar{u}_q \gamma_\mu (1 - \gamma_5) q)(\bar{\nu}_\mu \gamma^\mu (1 - \gamma_5) l) + \text{H.c.},$$

(38)

where the measured CKM matrix element is $V_{uj} = V_{uj}^0 (1 - \lambda \sin^4 \phi)$ and $V_{uj}^0$ is the CKM matrix element in the SM. The muon decay constant $G_F$ is identical to that in the SM if no lepton mixing is assumed $^{[8]}$. The additional parameters $\{V_{U3j}^D, V_{D3k}^D\}$ are canceled in Eq. (38) when we sum the $W$ and $W'$ contributions in the leading order of $\lambda$. Thus the unitarity violating term defined in Eq. (1) is derived

$$\Delta = 2 \lambda \sin^4 \phi.$$  

(39)

We show the unitarity violation $\Delta$ with respect to the $M_{Z'}$ in Fig. 3. With the best fit value of Eq. (33) from the low-energy neutral current data, under the constraints from the LEP bound and the atomic parity violation bound, we obtain the unitarity violating term as

$$\Delta \approx 0.0034,$$

(40)

which is close to the reported value $\Delta = 0.0031 \pm 0.0014 \ [2]$. 
V. CONCLUDING REMARKS

We explained the recent measurement on the unitarity violation of the CKM matrix by introducing the new physics with the separate SU(2) gauge symmetry on the third generation. The additional SU(2) symmetry leads to the nonuniversality of the electroweak gauge coupling, which leads to the unitarity violating term $\Delta$ of order $O(v^2/u^2)$ in the quark mixing matrix. We performed the updated analysis on the model parameters with the recent LEP+SLC data, low-energy neutral current data, and the atomic parity violation data. The model prediction for $\Delta$ with the best $\chi^2$ fit agrees very well with the value reported in the Ref. [1, 2]. In conclusion, it is a very interesting and instructive to find new physics model to explain the violation of unitarity in the CKM matrix even though the violation is still controversial. We show that the nonuniversal gauge interaction model is a good candidate for the new physics with the unitarity violation of the CKM matrix. The updated and precise measurement on the CKM matrix elements will probe the unitarity in the future.
