Abstract

Two vanadium(V) complexes derived from the bromo and chloro-substituted hydrazines N’-(4-bromo-2-hydroxybenzylidene)-2-chlorobenzohydrazide (H2L1) and N’-(3-bromo-5-chloro-2-hydroxybenzylidene)-3-methylbenzohydrazide (H2L2) with the formula [VOL1(OCH3)(CH3OH)] (1) and [VOL2(OCH3)(CH3OH)] (2) were newly synthesized and characterized by IR, UV-Vis and 1H NMR spectroscopy. The structures of H2L1 and the complexes were further confirmed by single crystal X-ray diffraction. Both vanadium complexes are mononuclear, with the metal atoms coordinated by the hydrazine ligands, methanol ligands, and methanolate ligands, and the oxo groups, forming octahedral geometry. The hydrazones and the vanadium complexes were assayed for the antimicrobial activities on Bacillus subtilis, Staphylococcus aureus, Escherichia coli, and Pseudomonas fluorescence, and the fungi Candida albicans and Aspergillus niger. The existence of the bromo and chloro groups in the hydrazone ligands may improve the antimicrobial property.

Keywords: Hydrazone; vanadium; crystal structure; antimicrobial property

1. Introduction

Hydrazine compounds and their metal complexes have received particular attention due to their interesting biological aspects like antibacterial,1 antifungal,2 and antitumor.3 It has been proved that the compounds with electron-withdrawing substituent groups can enhance their antimicrobial ability.4 Rai et al. reported some compounds with fluoro, chloro, bromo, and iodo-substituted groups, and their remarkable antimicrobial property.5 Schiff base complexes of vanadium have potential antibacterial property.6 Recently, our research group has reported some hydrazine vanadium complexes with bromo or chloro-substituent groups.7 In pursuit of novel vanadium complex based antimicrobial agents, in this work, the bromo and chloro-substituent groups are incorporated together in the hydrazone compounds N’-(4-bromo-2-hydroxybenzylidene)-2-chlorobenzohydrazide (H2L1) and N’-(3-bromo-5-chloro-2-hydroxybenzylidene)-3-methylbenzohydrazide (H2L2).
ylbenzohydrazide (H₂L²), and then coordinate with vanadium, to form two new vanadium(V) complexes, [VO(L¹)(OCH₃)(CH₃OH)] (1) and [VO²(L²)(OCH₃)(CH₃OH)] (2). The antimicrobial properties of the compounds are presented.

2. Experimental

2.1. Materials and Methods

4-Bromosalicylaldehyde, 3-bromo-5-chlorosalicylaldehyde, 2-chlorobenzohydrazide, 3-methylbenzohydrazide and VO(acac)₂ with AR grade were obtained from Sigma-Aldrich. All other chemicals were commercial obtained from Xiya Chemical Co. Ltd. Elemental analyses of C, H and N were carried out in a Perkin Elmer automated model 2400 Series II CHNS/O analyzer. The molar conductivity was determined using DDS-11A conductance device. FT-IR spectra were obtained on a Perkin-Elmer 377 FT-IR spectrometer with samples prepared as KBr pellets.

2.2. Synthesis of H₂L¹

4-Bromosalicylaldehyde (0.010 mol, 2.0 g) and 2-chlorobenzohydrazide (0.010 mol, 1.7 g) were reacted in methanol (50 mL) at room temperature for 30 min. The solvent was removed by distillation, and the residue was recrystallized from methanol to give colorless crystalline product. Yield 95%. Anal. Calc. for C₁₄H₁₀BrClN₂O₂: C, 47.55; H, 2.85; N, 7.92. Found: C, 47.37; H, 2.93; N, 7.81%. IR data (cm⁻¹): 3445 (w), 1605 (s), 955 (m). UV-Vis data (MeOH, λmax, nm): 225, 290, 310, 323, 402.

2.3. Synthesis of H₂L²

3-Bromo-5-chlorosalicylaldehyde (0.010 mol, 2.3 g) and 3-methylbenzohydrazide (0.010 mol, 1.5 g) were reacted in methanol (50 mL) at room temperature for 30 min. The solvent was removed by distillation, and the residue was recrystallized from methanol to give colorless crystalline product. Yield 95%. Anal. Calc. for C₁₅H₁₂BrClN₂O₄V: C, 39.90; H, 3.14; N, 5.65%. IR data (cm⁻¹): 3430, 3201, 1645, 1613. UV-Vis data (MeOH, λmax, nm): 275, 331.

2.4. Synthesis of Complex 1

H₂L¹ (0.10 mmol, 35 mg) and VO(acac)₂ (0.10 mmol, 26 mg) were reacted in methanol (10 mL) at reflux for 1 h and then cooled to room temperature. Block brown single crystals of the complex, suitable for X-ray diffraction, were grown from the solution upon slowly evaporation within a few days. The crystals were isolated by filtration. Yield 45%. Anal. calc. for C₁₄H₇BrClN₂O₂V: C, 39.90; H, 3.14; N, 5.82; found: C, 39.72; H, 3.26; N, 5.95%. IR data (cm⁻¹): 3451 (w), 1607 (s), 956 (m). UV-Vis data (MeOH, λmax, nm): 275, 331.

2.5. Synthesis of Complex 2

H₂L² (0.10 mmol, 37 mg) and VO(acac)₂ (0.10 mmol, 26 mg) were reacted in methanol (10 mL) at reflux for 1 h and then cooled to room temperature. Block brown single crystals of the complex, suitable for X-ray diffraction, were grown from the solution upon slowly evaporation within a few days. The crystals were isolated by filtration. Yield 38%. Anal. calc. for C₁₃H₁₂BrClN₂O₄V: C, 41.20; H, 3.46; N, 5.65; found: C, 41.32; H, 3.53; N, 5.57%. IR data (cm⁻¹): 3445 (w), 1605 (s), 955 (m). UV-Vis data (MeOH, λmax, nm): 273, 327.

2.6. X-ray Crystallography

X-ray diffraction was carried out at a Bruker APEX II CCD area diffractometer equipped with MoKa radiation (λ = 0.71073 Å). The collected data were reduced with
SAINT\textsuperscript{8} and multi-scan absorption correction was performed using SADABS.\textsuperscript{9} The structures of the complexes were solved by direct method, and refined against $F^2$ by full-matrix least-squares method using SHELXTL.\textsuperscript{10} All of the non-hydrogen atoms were refined anisotropically. The hydrogen atoms bond to N and O atoms were located from electronic density maps with O‒H and N‒H groups refined fixing the bond lengths. The $U_{iso}(H)$ were set to 1.5 $U_{eq}(O)$ and 1.2 $U_{eq}(N)$. The remaining hydrogen atoms were placed in calculated positions and constrained to ride on their parent atoms. The crystallographic data and refinement parameters for H$_2$L\textsubscript{1} and the complexes are listed in Table 1. Selected bond lengths and angles are listed in Table 2.

### 2.7. Antimicrobial Assay

The antibacterial activities of the hydrazone compounds and the vanadium complexes were tested against \textit{B. subtilis}, \textit{S. aureus}, \textit{E. coli}, and \textit{P. fluorescence} using MH (Mueller–Hinton) medium. The antifungal activities of the compounds were tested against \textit{C. albicans} and \textit{A. niger} using RPMI-1640 medium. The MIC values of the tested compounds were determined by a colorimetric method using the dye MTT.\textsuperscript{11} A stock solution of the compound (150 μg mL$^{-1}$) in DMSO was prepared and graded quantities (75, 37.5, 18.8, 9.4, 4.7, 2.3, 1.2, 0.59 μg mL$^{-1}$) were incorporated in specified quantity of the corresponding sterilized liquid medium. A specified quantity of the medium containing the compound was poured into micro-titration plates. Suspension of the microorganism was pre-
pared to contain approximately $1.0 \times 10^5$ cfu mL$^{-1}$ and applied to microtitration plates with serially diluted compounds in DMSO to be tested and incubated at 37 °C for 24 h and 48 h for bacteria and fungi, respectively. Then the MIC values were visually determined on each of the microtitration plates, 50 μL of PBS (phosphate buffered saline 0.01 mol L$^{-1}$, pH = 7.4) containing 2 mg of MTT mL$^{-1}$ was added to each well. Incubation was continued at room temperature for 4–5 h. The content of each well was removed and 100 μL of isopropanol containing 5% HCl (1 mol L$^{-1}$) was added to extract the dye. After 12 h of incubation at room temperature, the optical density was measured with a microplate reader at 550 nm.

3. Results and Discussion

3.1. Synthesis and Characterization

The hydrazones H$_2$L$_1$ and H$_2$L$_2$ were readily prepared by the condensation reaction of a 1:1 molar ratio of 4-bromosalicylaldehyde with 2-chlorobenzohydrazide, and 3-bromo-5-chlorosalicylaldehyde with 3-methylbenzohydrazide, respectively in methanol. Single crystals of H$_2$L$_1$ were obtained by slow evaporation of its methanolic solution. However, it is difficult to obtain the single crystals of H$_2$L$_2$ even with the attempts of various solvents. The vanadium complexes were obtained by the reaction of the hydrazones with VO(acac)$_2$ in methanol, followed by recrystallization. Elemental analyses of the hydrazones and the vanadium complexes are in accordance with the molecular structures determined by the single crystal X-ray analysis.

3.2. Spectroscopic Studies

In the spectra of the hydrazones H$_2$L$_1$ and H$_2$L$_2$, and the vanadium complexes, the weak bands in the range 3400–3500 cm$^{-1}$ are attributed to the vibration of the O–H bonds. The sharp bands of the hydrazones H$_2$L$_1$ and H$_2$L$_2$ observed at 3200–3210 cm$^{-1}$ are assigned to the vibration of the N–H bonds. The strong absorptions at 1643–1645 cm$^{-1}$ of the hydrazones are generated by the vibrations of the C=O bonds, whereas the bands at 1613–1614 cm$^{-1}$ by the C=N bonds. The absence of the ν(C=O) and ν(N–H) bands, which present in the spectra of the hydrazones, implies the enolization of the amide functionality upon coordination to the V atoms. The strong absorption bands at 1605–1607 cm$^{-1}$ can be assigned to the stretching vibrations of the C=N bonds. The typical bands at 955–956 cm$^{-1}$ for the complexes could be clearly identified to the ν(V=O) for the complexes.$^{12}$

In the UV-Vis spectra of the hydrazones and the vanadium complexes, the bands at 320–340 nm are assigned to the intra-ligand π→π* absorptions. In the spectra of the vanadium complexes, the lowest energy transition bands observed at 400 nm are due to the LMCT transition as charge transfer from p-orbital on the lone-pair of ligands’ oxygen atoms to the empty d-orbital of the vanadium atoms. The other mainly LMCT and to some extent π→π* bands appear at about 275 nm for the vanadium complexes are attributed to the oxygen donor atoms bound to V atoms.$^{12}$

The $^1$H NMR spectra of the hydrazones H$_2$L$_1$ and H$_2$L$_2$ exhibit OH(phenolic) resonances at 12.32 and 12.51 ppm, respectively. Signals for one CH proton at 8.66 ppm, and one NH proton at 11.31 ppm for H$_2$L$_1$, and signals for one CH=N proton at 8.64 ppm, and one NH proton at 11.27 ppm for H$_2$L$_2$. Signals for aromatic protons are found in the 7.69–7.12 ppm range. Signals for methyl protons of H$_2$L$_2$ are found at 2.32 ppm.

3.3. Structure Description of H$_2$L$_1$

Molecular structure of H$_2$L$_1$ is shown in Figure 1. The molecule adopts E configuration about the methyldene group. The distance of the C7–N1 group, 1.266(8) Å, indicates it a typical double bond. The distance of the C8–N2 bond (1.352(9) Å) is shorter, and that of the C8–O2 bond (1.222(7) Å) for the –C(O)–NH– unit is longer than usual, implies the conjugation effects in the hydrazone molecule. The bond lengths and angles in this compound are within normal values.$^{14}$ The two aromatic rings C1–C6 and C9–C14 form a dihedral angle of 20.5(5)°. In the crystal structure of the compound, the molecules

Figure 1. A perspective view of H$_2$L$_1$ with the atom labeling scheme. Thermal ellipsoids are drawn at the 30% probability level. Hydrogen bond is shown as a dotted line.
are linked through N–H⋯O and non-classical C–H⋯O hydrogen bonds (Table 3), to form chains along the α-axis direction (Figure 2).

3. 4. Structure Description of the Complexes

Molecular structures of the vanadium complexes 1 and 2 are shown in Figures 3 and 4, respectively. The coordination spheres around the V atoms are best described as distorted octahedral geometry. The hydrazones, act as tridentate ligands, chelate the V atoms in a meridional fashion, generating one five and one six-membered rings with bite angles of 73.6(2)–74.1(2)° and 82.9(2)–83.5(2)°, respectively. This is not uncommon for this type of ligand systems.13 Each hydrazone ligand lies in a plane with one hydroxylato ligand which lies trans to the hydrazone imino nitrogen atom. The oxygen atoms of the methanol ligands trans to the oxo oxygen atoms complete the distorted octahedral coordination spheres at rather elongated distances of 2.306(5)–2.329(6) Å, due to the trans effects of the oxo groups. This is accompanied by significant displacements of the V atoms of complexes 1 and 2 from the planes defined by the four basal donor atoms toward the apical oxo oxygen atoms by 0.295(3) and 0.299(3) Å, respectively. As

![Figure 2. Molecular packing structure of H₂L₁, with hydrogen bonds shown as dotted lines.](image)

![Figure 3. A perspective view of complex 1 with the atom labeling scheme. Thermal ellipsoids are drawn at the 30% probability level.](image)
expected, the hydrazone ligands coordinate in their doubly deprotonated enolate form which is consistent with the observed O2–C8 and N2–C8 bond lengths of 1.28–1.31 Å and 1.29–1.31 Å. This agrees well with reported vanadium complexes with the enolate form of this type of ligands.14

In the crystal packing structure of complex 1, the molecules are linked by hydrogen bonds (Table 3), leading to the formation of dimers (Figure 5). In the crystal packing structure of complex 2, the molecules are linked by hydrogen bonds (Table 3), leading to the formation of chains along the c-axis direction (Figure 6).

### 3.5. Antimicrobial Activity

The hydrazone compounds and the vanadium complexes were screened for antibacterial activities against two Gram (+) bacterial strains (*Bacillus subtilis* and *Staphylococcus aureus*) and two Gram (–) bacterial strains (*Escherichia coli* and *Pseudomonas fluorescence*) by MTT method. The MIC (minimum inhibitory concentration, μg mL–1) values of the compounds against four bacteria are listed in Table 4. Penicillin G was used as the standard drug. Both hydrazone compounds show medium activity against *B. subtilis* and *S. aureus*, weak activity against *E. coli*, and no activity against *P. fluorescence*. H2L2 has stronger activities against the bacteria than H2L1 except for *P. fluorescence*. The vanadium complexes, in general, have stronger activities against the bacteria than the free hydrazones. The complexes have strong activities against *B. subtilis*, *S. aureus* and *E. coli* which are comparable to Penicillin G. Complex 1 has no activity against *P. fluorescence*, while complex 2 has weak activity. Both complexes have no activity on the fungal strains *Candida albicans* and *Aspergillus niger*.

Interestingly, the bromo and chloro-containing hydrazone H2L2 is more active than the bromo and methoxy-containing hydrazones N’-(3-bromo-2-hydroxybenzylidene)-3-hydroxy-4-methoxybenzohydrazide and N’-(3-bromo-2-hydroxybenzylidene)-3,5-dimethoxybenzohydrazide.7a Subsequently, the complex 2 with bromo and chloro-containing hydrazone ligand is more active than the vanadium complex with bromo and methoxy-containing hydrazone ligand on *S. aureus* and *P. fluorescence*.7a

| O3–H3···N2v  | 0.85(1) | 1.98(1)  | 2.842(8) | 176(3)         |
| C13–H13···O5vi | 0.93   | 2.56     | 3.362(3) | 145(4)         |

Symmetry codes: (i) ½ + x, ½ – y, ½ + z; (ii) x, y, 1 + z; (iii) 1 – x, – y, 1 – z; (iv) 1 – x, – y, 2 – z; (v) –x, 1 – y, 1 – z; (vi) –x, 1 – y, 2 – z.
As compared with the chloro-containing hydrazone 2-chloro-$\text{N}'$-(3,5-dichloro-2-hydroxybenzylidene)benzohydrazide,$^7c$ $\text{H}_2\text{L}_1$ is obviously weak for all the bacteria, while $\text{H}_2\text{L}_2$ is similar except for $S.\text{aureus}$, a little weaker than the reported one. As for the vanadium complexes, complex 1 is similar to the reported vanadium complex with chloro-containing hydrazone ligand, while complex 2 is superior to the reported one against $B.\text{subtilis}$, $E.\text{coli}$ and $P.\text{fluorescence}$. $^7c$ Moreover, when compared with the vanadium complexes with chloro and fluoro-containing hydrazone ligands, both complexes are to some extent have higher MIC values.$^{7b,15}$

When compared with the vanadium complexes with Schiff base ligand 2-(((2-hydroxyethyl)imino)methyl)-6-methylphenol and the pyrone ligands 3-hydroxy2-methyl-4H-pyran-4-one or 2-ethyl-3-hydroxy-4H-pyran-4-one,$^{16}$ and the vanadium complexes with the ligands $\text{N}'$-(5-chloro-2-hydroxybenzylidene)pivalohydrazide and 3-hydroxy2-methyl-4H-pyran-4-one or 2-ethyl-3-hydroxy-4H-pyran-4-one,$^{17}$ the complexes 1 and 2 in this work is weaker for the bacteria $S.\text{aureus}$, $E.\text{coli}$, and $C.\text{albicans}$. $^{16}$ The present complexes have higher activities against $B.\text{subtilis}$, $S.\text{aureus}$ and $E.\text{coli}$, when compared with the vanadium complex with the ligands $\text{N}'$-(3-bromo-2-hydroxybenzylidene)picolinohydrazide and 2-hydroxybenzohydroxamate. Interestingly, when the ligands changed to 2-chloro-$\text{N}'$-(2-hydroxy-3-methoxybenzylide-
ne)benzohydrazide and 2-hydroxybenzohydroxamate, the present complexes have higher activities against \textit{B. subtilis} and \textit{E. coli}, while lower activities against \textit{S. aureus}.\textsuperscript{18}

### 3. 6. TGA Analysis

The thermograms of complexes 1 and 2 are shown as Figures 7 and 8, respectively. The decomposition mode of both complexes is similar. The neutral methanol ligands are removed between 80–120 °C, and the deprotonated methanol ligands are removed between 115–120 °C for complex 1 and 130–140 °C for complex 2. Then, the complexes continue to decompose between 150–510 °C. The residue remained about 510 °C is 17% for complex 1 and 16% for complex 2, which is in accordance with the expected amount of V$_2$O$_5$.

### Supplementary Data

CCDC 2012695 (H$_2$L$^1$), 1891034 (1) and 2012696 (2) contain the supplementary crystallographic data for the compounds. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.
