Introduction

Plant cell wall is mainly composed of complex structural polysaccharides like cellulose and hemicellulose [1,2]. The heteropolymers of pentoses like D-xylose, D-arabinose and hexoses viz. D-mannose, D-glucose and D-galactose constitute the hemicellulose. Often, xylans are heteropolysaccharides with 1,4-linked-β-D-xylopyranosyl backbone chains containing arabinose, glucuronic acid, or its 4-O-methyl ether, acetic, ferulic, and p-coumaric acids side chains depending mainly on the source of xylans [3]. Rye arabinoxylans contain arabinose and xylose in the A/X ratio of 0.49-0.62 and also ferulate residues attached to arabinose as esters at its O-5 position [4] but in wheat arabinoxylans the arabinose to xylose ratios [A/X] varies from 0.47 to 0.58 [5]. The L-arabinosyl residues are often found in hemicelluloses, such as arabinan, arabinoxylan, gum arabic and arabinogalactan. The cereal arabinoxylans are composed majorly of a backbone of 1,4-linked-β-D-xylopyranosyl residues substituted with single α-L-arabinofuranosyl substituents attached to the O-2, O-3 or to both O-2,5 of the xylose residues [6,7]. It has been documented that α-L-arabinofuranosyl and to a lesser extent α-L-arabinopyranosyl side chains are attached to the β-D-galactopyranose main chain by 1,3- and 1,6-linkages in type II arabinogalactans [4,6,8,9,10]. The α-L-arabinofuranosidase (EC 3.2.1.55) are enzymes known to release terminal α-1,2-, α-1,3- and α-1,5-α-L-arabinofuranosyl residues from hemicellulose such as arabinoxylan and other L-arabinose containing polysaccharides [6,9]. Arabinofuranosidase have been reported from a few glycoside hydrolase families (GHs) viz., GH30 [11], GH43 [12,13], GH51 [14,15,16], GH54 [17] and GH62 [18,19]. The GH43 arabinoxylan arabinofuranohydrolase from Bacillus subtilis reported by Bourgois et al., 2007 [12] specifically released arabinofuranosyl residues from the monosubstituted C-(O)-2 and C-(O)-3 xylopyranosyl residues on the xylan backbone. Whereas, Cartmell et al., 2011 [13] reported an arabinan-specific GH43 (α-1,2-arabinofuranosidase) from Cellvibrio japonicus capable of cleaving the α-1,2-arabinofuranosyl decorations in simple or double substitutions. The arabinofuranosidase (Ar51B) from Clostridium stercorarium as reported by Aldesberger et al., (2004) was able to release α-L-arabinose residues from de-esterified arabinoxylan [15]. The arabinofuranosidase (ArAra51) from Clostridium thermocellum as described by Taylor et al., (2006) catalyzed the hydrolysis of both α-1,5-linked arabinio-oligosaccharides and the α-1,3 arabinosyl side chain of xylan with equal efficiency [16]. α-L-Arabinofuranosidases have been used syner-
Carbohydrate binding modules (CBMs) are known to have cellulose as major content but they also contain 20% hemicellulose which mainly consists of pentose such as xylose and arabinose [1,2]. In the past α-L-arabinofuranosidases received less importance in the production of bio-ethanol because pentoses are less efficiently converted to ethanol than hexose sugars [20]. But recently they have been used along with Candida shehatae that utilizes the pentose sugars for bio-ethanol production from cellulose waste like mango and poplar leaves [21]. Also L-arabinose has been shown to inhibit intestinal sucrose and reduce the glycaemic response after sucrose ingestion in animals [22]. The carbohydrate binding modules (CBMs) are the non-catalytic modules known to help or bring the ingestion in animals [22]. The carbohydrate binding modules contain up to 200 amino acids and can be found attached as single, double or triple domains in one protein, located at both C- or N-terminal within the parental protein [23,24].

Biochemical, structural and functional characterization of GH43Araf and CαGH43 is essential as all the α-L-arabinofuranosidases have the same inverting mechanism of catalysis but the enzyme activities are different [http://www.eazy.org/GH43.html]. In the present study the recombinant proteins CαGH43 and its truncated derivative CαGH43 were investigated and biochemically, structurally and functionally characterized. To our knowledge this is the first report of any α-L-arabinofuranosidase from Clostridium thermocellum showing the ability to hydrolyze both 4-nitrophenyl-α-arabinofuranoside (pNPA) and 4-nitrophosphoryl-α-arabinopyranoside (pNPα).

Materials and Methods

Bacterial Strains and Plasmid
The genomic DNA of Clostridium thermocellum was a gift from Professor Carlos Fontes, Faculdade de Medicina Veterinaria, Lisbon, Portugal. Escherichia coli (DH5α) cells were used for cloning, whereas, E. coli BL-21 (DE3) and E. coli BL-21 (DE3) pLysS cells were used as expression host. The plasmids used for cloning and expression were pET-21a(+) and pET-28a(+) All the above mentioned items were procured from Novagen (Madison, USA).

Fine Chemicals, Natural and Synthetic Substrates for Enzyme Assay
Thin layer chromatography (TLC) and high pressure anion exchange chromatography (HPAEC) standards like xylose, L-arabinose, cellullose, chelating agent, EGTA and NaOH solution (50%, w/v) were procured from Sigma-Aldrich Chemicals Co., USA. Rye arabinoxylan, wheat arabinoxylan (soluble and insoluble), arabinogalactan, sugar beet arabinan, rhamnogalactouronan, 1,3-α-L-arabinobiose and 1,5-α-L-arabinotetraose were procured from Megazyme International, Ireland. Oat spelt xylan, birchwood xylan, beechwood xylan, β-D-glucan, carboxy methylelulose (CMC), carboxy ethylelulose (CEC) and synthetic pN-glucosides like pN-α-L-arabinofuranoside (pNPA) and pN-α-L-arabinopyranoside (pNPα), were purchased from Sigma-Aldrich Chemicals Co., USA.

Gene Amplification and Cloning
Oligonucleotide primers containing Nhel and Xhol restriction sites were designed and the DNA encoding CαGH43Araf (GenBank Accession No: ABN32563.1; comprising of CGH43, CCBM6A and CCBM6B domains, sequence range 1545911 to 1570631) and truncated gene CGH43 were amplified from genomic DNA of C. thermocellum (7.7 mg using 2.5 U of Pfu DNA polymerase (Stratagene, USA). A 50 µl PCR reaction mixture contained Mg²⁺ ions (2.5 mM), dNTPs (1.6 mM) forward and reverse primer (0.45 µM) and PCR-grade water (Sigma, USA). The primers used for amplifying CαGH43Araf were forward 5'-ctctgatatgc-aatgactatcg-3', reverse 5'-cactgctggtcttacatgc-3'. Primers for CαGH43 have been reported previously [21]. The PCR amplification cycles used were: denaturation at 94°C for 4 min followed by 30 cycles of i) denaturation at 94°C for 30 s, ii) annealing at 55°C for 60 s and iii) extension at 72°C for 2 min followed by a final extension at 72°C for 10 min. The PCR amplified DNA of CαGH43Araf was cloned in Xhol-Xhol digested pET-21a (+) vector while PCR DNA of CαGH43 was cloned earlier in pET-28a (+) vector [21], resulting in respective cloned plasmids. The positive clones were confirmed by Mde-Xhol digestion and DNA sequencing of recombinant plasmid. Thereafter, E. coli (DH5α) cells were transformed with above recombinant plasmids (pCαGH43Araf and pCαGH43). The transformed cells were grown on LB-agar plates supplemented with ampicillin (100 µg ml⁻¹) in case of CαGH43Araf and kanamycin (50 µg ml⁻¹) in case of CαGH43 at 37°C. Positive clones were screened by restriction digestion analysis of the isolated recombinant plasmids DNAs from the cells. The truncated enzyme CGH43 was amplified, cloned and expressed earlier and was reported [21].

Expression and Purification of Recombinant α-L-arabinofuranosidase
E. coli BL-21 (DE3) pLysS cells were used for expressing CαGH43 as described earlier [21], whereas, E. coli BL-21 (DE3) cells were transformed with recombinant plasmid pCαGH43Araf. The cells were grown in 100 ml LB medium containing ampicillin (100 µg ml⁻¹) for growing CαGH43Araf and kanamycin (50 µg ml⁻¹) for growing CαGH43 at 37°C with 180 rpm till mid-exponential

Figure 1. The molecular architecture of CαGH43Araf shows modular structure with an N-terminal family 43 glycoside hydrolase (CGH43) catalytic module (903 bp), a C-terminal family 6 carbohydrate binding module (CCBM6A, 402 bp) and another family 6 Carbohydrate binding module (CCBM6B, 405 bp) sandwiched between these two modules.

doi:10.1371/journal.pone.0073575.g001
The cells were harvested at 10,000 g at 4°C for 15 min using centrifuge (Sigma, 4 K 15) and the resulting cell pellets were re-suspended in 20 mM sodium phosphate buffer pH 7.4. Then the cells were sonicated (Sonics, Vibra cell) on ice for 8 min (5 s on/15 s off pulse; 33% amplitude) and again centrifuged at 19,000 g at 4°C for 30 min to get the cell free extract. The recombinant proteins from the cell free extracts were purified in a single step by immobilized metal ion affinity chromatography (IMAC) using sepharose columns (GE Healthcare, HiTrap chelating) and further dialyzed against 20 mM sodium phosphate buffer pH 5.7 for CtGH43 and 20 mM sodium acetate buffer pH 5.4 for Ct43Araf following the method as reported previously [21]. The purity and molecular mass of recombinant proteins were verified by SDS-PAGE [26].

### Table 1. Substrate specificity of Ct43Araf and CtGH43 from C. thermocellum.

| Substrates (polysaccharides) | Specific Activity of Ct43Araf (U/mg) | Specific Activity of CtGH43 (U/mg) |
|-----------------------------|--------------------------------------|-----------------------------------|
| Arabinoxylan, (Rye)         | 4.70 ± 0.07                          | 5.00 ± 0.08                        |
| Arabinoxylan (wheat, soluble)| 2.50 ± 0.03                          | 2.70 ± 0.03                        |
| Xylan (Oat spelt)            | 1.70 ± 0.08                          | 1.80 ± 0.07                        |
| Arabinoxylan (wheat, insoluble) | 1.20 ± 0.10                          | 1.10 ± 0.10                        |
| Xylan (Beechwood)            | 1.00 ± 0.04                          | 0.90 ± 0.04                        |
| Xylan (Birchwood)            | 0.70 ± 0.03                          | 0.80 ± 0.04                        |
| Arabinogalactan             | 0.25 ± 0.05                          | 0.32 ± 0.05                        |
| Arabinan (sugar beet)        | 0.22 ± 0.04                          | 0.23 ± 0.04                        |
| Carboxy methyl cellulose     | ND                                   | ND                                 |
| Carboxy ethylcellulose       | ND                                   | ND                                 |

All the assays were performed at 50°C using 20 mM sodium phosphate (pH 5.7) buffer for Ct43Araf and 20 mM sodium acetate (pH 5.4) buffer for CtGH43. The assays were performed in triplicates. The incubation time and other conditions for reducing sugar estimation were as same as described in the Materials and Methods section.

**1,5-α-L-arabinobiose** 0.25 ± 0.04 0.24 ± 0.04

**1,5-α-L-arabinotetraose** 0.22 ± 0.04 0.20 ± 0.04

*It was prepared by Megazyme (Ireland) via controlled enzymatic hydrolysis of de branched sugar beet arabian as described in the manufacturer's instructions.

ND = No activity detected.

**Natural Substrates**

The enzyme assay for Ct43Araf was performed using 20 mM sodium phosphate buffer (pH 5.7), whereas, the assay for CtGH43 was carried out in 20 mM sodium acetate buffer (pH 5.4). The 100 μl reaction mixture contained 1.0%, w/v substrate, 10 μl of enzyme (Ct43Araf/0.45 mg ml⁻¹ or CtGH43 0.5 mg ml⁻¹) and in both cases the reaction mixture was incubated at 50°C for 15 min. The enzyme activity was determined by measuring the reducing sugar by the method of Nelson and Somogyi [27,28]. The concentration of reducing sugar was estimated using a standard curve of L-arabinose as both Ct43Araf and CtGH43 predominantly showed α-L-arabinofuranosidase activity. One unit of activity was defined as the amount of enzyme which produced 1 μmole of L-arabinose per min under the optimized condition of temperature and pH. For studying the pH profile of Ct43Araf, 20 mM sodium acetate buffer, pH 4.0–5.6, 20 mM sodium...
phosphate buffer, pH 5.7–7.5, 20 mM Tris/HCl, pH 7.5–8.0, buffer were used in enzyme assays that employed 1.0 (%, w/v) rye arabinoxylan, similar to the method employed for optimization of CgGH43 [21]. The optimum temperature and thermostability of C43Araf was determined by performing assays at different temperatures following the method reported earlier [21]. The kinetic parameters of C43Araf and CgGH43 were determined by performing assays at varying concentrations of the soluble substrates such as rye arabinoxylan, wheat arabinoxylan, oat spelt xylan, beechwood xylan and birchwood xylan and insoluble wheat arabinoxylan under the optimized condition of temperature and pH. The optimum pH and pH stability profile was generated by performing the enzyme assays at the optimum temperature of 50°C. The experiments were performed in triplicate.

Substrate Specificity of C43Araf and CgGH43 with Synthetic p-nitrophenyl-glycosides

The assays of C43Araf and CgGH43 with synthetic p-nitrophenyl glycosides (pNP-glycosides) viz., p-nitrophenyl-α-L-arabinofuranoside (pNPA) and p-nitrophenyl-β-L-arabinopyranoside (pNPA) were carried out by estimating the release of 4-nitrophenol (pNP) at 405 nm using a UV-Visible spectrophotometer (Varian, Cary 100 Bio) following the method described by Cartmell et al. 2011 [13]. The enzyme reaction was performed in 1.0 ml reaction mixture containing pNPA or pNPAP in 50 mM sodium phosphate buffer (pH 6.0), 20 μl of enzyme (C43Araf 0.45 mg ml⁻¹ or CgGH43 0.5 mg ml⁻¹) incubated for 15 min at 50°C in a peltier temperature controller (Varian, Cary 100 Bio). The kinetic parameters of C43Araf and CgGH43 with pNPA or pNPAP were determined by varying their concentrations in the range 20 to 500 μM. The initial (pseudo-first order) rates of C43Araf and CgGH43 with both the pNP-glycosides were measured in order to calculate the kinetic parameters. Continuous readings were recorded every one second for the initial linear absorbance range (0–15 mins) with an array of concentrations (20–500 μM) of pNP-glycosides. The reaction was stopped after 15 min by the addition 0.5 M sodium carbonate to make the reaction mixture highly alkaline (around pH 11.0). The assays were performed in triplicates. The released p-nitrophenol was quantified using the molar extinction coefficient of 24150 litre mol⁻¹ cm⁻¹ as reported by Cartmell et al. 2011 [13].

### Table 2. Kinetic properties and catalytic efficiencies of C43Araf and CgGH43 from C. thermocellum.

| Substrates                  | Km (mg ml⁻¹) | kat (min⁻¹) | kcat/Km (min⁻¹ mg⁻¹ ml⁻¹) |
|----------------------------|--------------|-------------|--------------------------|
| Natural polysaccharides    |              |             |                          |
| Rye arabinoxylan           | 0.08±0.002   | 298.0±8.0   | 3.6×10⁴                  |
| Wheat arabinoxylan (soluble)| 0.078±0.005 | 209.0±2.0   | 2.7×10⁴                  |
| Wheat arabinoxylan (insoluble)| 0.01±0.001 | 61.0±18.0   | 6.1×10⁴                  |
| Oat spelt xylan            | 0.08±0.002   | 67.0±2.0    | 8.3×10⁴                  |
| Birchwood xylan            | 0.09±0.002   | 29.0±1.0    | 3.2×10⁴                  |
| Beechwood xylan            | 0.8±0.003    | 26.0±2.0    | 3.3×10⁴                  |
| Synthetic pNP-glycosides   |              |             |                          |
| pNP-α-L-arabinofuranoside  | 0.05±0.002   | 283.0±2.0   | 5.6×10⁴                  |
| pNP-β-L-arabinopyranoside  | 0.093±0.003  | 210.0±4.7   | 2.2×10⁴                  |
| CgGH43                     |              |             |                          |
| Natural polysaccharides    |              |             |                          |
| Rye arabinoxylan           | 0.08±0.002   | 298.0±8.0   | 3.6×10⁴                  |
| Wheat arabinoxylan (soluble)| 0.078±0.005 | 209.0±2.0   | 2.7×10⁴                  |

| Oat spelt xylan            | 0.08±0.002   | 67.0±2.0    | 8.3×10⁴                  |
| Birchwood xylan            | 0.09±0.002   | 29.0±1.0    | 3.2×10⁴                  |
| Beechwood xylan            | 0.8±0.003    | 26.0±2.0    | 3.3×10⁴                  |

The assays with natural substrates were carried out with 20 mM sodium phosphate buffer (pH 5.7) for C43Araf and sodium acetate buffer (pH 5.4) for CgGH43 at 50°C. The assays were performed in triplicates. The incubation time and other conditions for reducing sugar estimation were as same as described in the Materials and Methods section. The assays with synthetic pNP-glycosides were carried out in 20 mM sodium phosphate buffer pH 5.7.

doi:10.1371/journal.pone.0073575.t002

**Effects of Metal Ions and Chemical Agents**

The effects of different metal cations on the activity of C43Araf (0.45 mg ml⁻¹) and CgGH43 (0.5 mg ml⁻¹) were determined using 100 μl reaction mixture (in duplicates) with oat spelt xylan (1%, w/v) as the substrate and adding respective metal salt at low molar concentrations (up to 20 mM). Assays for C43Araf using 20 mM sodium phosphate buffer (pH 5.7) and for CgGH43 using 20 mM sodium acetate buffer (pH 5.4) were performed at 50°C. The reaction mixtures in both the cases were subjected to 15 min of incubation. The blank with substrates having the respective salts were also assayed in parallel. The effects of various salts of Na⁺, Ca²⁺, Mg²⁺, Mn²⁺, Zn²⁺, Cu²⁺, Co²⁺, Ni²⁺, Al³⁺ and chelating agents like disodium EDTA and disodium EGTA were studied by varying their concentrations from 2.0–20.0 mM in the enzyme-substrate reaction mixture. The enzyme activity was calculated by estimating the reducing sugars as described above.

**Thin Layer Chromatography of C43Araf Hydrolyzed Products**

The qualitative analysis of C43Araf hydrolyzed products of natural substrates was performed by thin layer chromatography (TLC) on silica gel-coated aluminium plate (TLC Silica gel 60 F254, 20×20 cm, Merck) for detecting the released sugars. The enzyme catalyzed reactions with 1% (w/v) substrate (rye arabinoxylan, wheat arabinoxylan or oat spelt xylan) were carried out in 100 μl reaction mixture maintaining the optimized condition of temperature and pH as mentioned above. The 100 μl reaction mixture was then precipitated with 2 volumes of acetone and centrifuged at 4°C at 13,000 g for 5 min [29]. The supernatant was transferred to another micro-centrifuge tube and the reaction product precipitate was concentrated by evaporating the acetone. Then 2.0 μl of sample (enzyme-substrate reaction product) as well as of standard (L-arabinose and D-xylose) solutions (1.0 mg ml⁻¹) were loaded on the TLC plate. The plate was dried for few min and kept in the developing chamber saturated with the developing solution (mobile phase). The mobile phase consisted of acetic acid-isopropanol-water-acetonitrile in the ratio 4:10:11:14 [29]. At the end of the run, migrated sugars were visualized by immersing the chromatogram in a solution (sulphuric acid: methanol: 5:95, v/v; and 2-napthol 5.0%, w/v). The TLC plates were then dried in a hot-air oven at 80°C for 20 min. The migrated sugars appeared as blue spots on the TLC plate.

*Novel α-L-Arabinofuranosidase from C. thermocellum*
HPAEC Analysis of Polysaccharide Hydrolysis Product by Ct43Araf

Ct43Araf (4.7 U/mg, 0.5 mg/ml) catalyzed reactions with 1% (w/v) substrate (rye arabinoxylan, wheat arabinoxylan and oat spelt xylan) was carried out in 100 ml reaction mixture maintaining the optimal assay conditions as mentioned above. The 100 ml reaction mixture was incubated for 30 min at 50°C. The reaction was stopped by boiling the reaction mixture in a boiling water bath for 5 min. The 100 ml reaction mixtures were treated with 2 volumes of acetone to precipitate the remaining polysaccharides (substrates) and then centrifuged at 13,000 g for 10 min at 4°C. The supernatant containing the liberated sugar was transferred to another micro centrifuge tube and the acetone was removed by evaporation. The supernatant (50 µl) was diluted to 500 µl by adding ultra-pure (MilliQ) water and filtered through syringe filter using 0.2 µm membrane. The liberated sugars released due to the polysaccharide hydrolysis by enzyme reaction were analysed by high pressure anion exchange chromatography (HPAEC) using ion chromatography system (Dionex, ICS-3000). From the filtered 500 µl, 25 µl of sample (liberated sugars) was run on CARBO-PACK™ PA-20 column (150×6×3 mm, Dionex), attached with CarboPac™ PA20 guard column (30×6×3 mm, Dionex) with Borate and Amino trap columns which removed impurities and provided high resolution. The instrument (Dionex, ICS-3000) was kept at constant temperature of 30°C during the analysis. The sample loop (sample loaded) size was kept to 25.0 µl and the flow rate was maintained at 0.3 ml min⁻¹. The elution of liberated sugars released due to enzymatic reaction was carried out with 50.0 mM sodium hydroxide (Sigma, USA) using pulsed amperometric detector (PAD). L-arabinose and D-xylose (10 mg ml⁻¹) were used as standards. The solutions of standards as well as samples were filtered by passing through 0.2 µm filter before loading on the column.

Protein Melting Study of Ct43Araf and CtGH43

Protein melting curves were generated by subjecting recombinant proteins (Ct43Araf and CtGH43) to varying temperatures and measuring the change in the absorbance at 280 nm (tryptophan absorption maximum) by a UV-Visible spectrophotometer (Varian, Cary 100-Bio) following the method of Dvortsov et al. [30]. The column (IMAC) purified Ct43Araf was dialyzed against 20 mM sodium phosphate buffer, pH 5.7, while, purified CtGH43 was dialyzed against 20 mM sodium acetate buffer, pH 5.4. The protein concentration for both Ct43Araf and CtGH43 were kept at 0.4 mg ml⁻¹. The absorbance at 280 nm was measured at different temperatures varying from 40-90°C using a peltier temperature controller. The protein solutions (1 ml) of Ct43Araf/

Table 3. Maximum effect on enzyme activity of Ct43Araf and CtGH43 from Clostridium thermocellum at maximum concentration of metal ions and chelating agents.

No additives were added in control and the activity was taken as 100%. doi:10.1371/journal.pone.0073575.t003

Figure 3. Thin layer chromatography analysis of reaction products of Ct43Araf. Dark spots on TLC plate show the standards L-arabinose, D-xylose and cellobiose (spots 1, 2 and 3, respectively) while spots 4, 5 and 6 represent hydrolyzed products from rye arabinoxylan, wheat arabinoxylan and oat spelt xylan, respectively, showing that only L-arabinose is released as the breakdown product. doi:10.1371/journal.pone.0073575.g003
and C\textit{G}H43 were kept at the particular temperature for 10 min to attain the equilibrium. Similar experiment was carried out; with the addition of 10 mM CaCl\textsubscript{2} in the 1 ml enzyme (0.4 mg/ml) solution and the temperature was then varied. The experiment was repeated with the addition of CaCl\textsubscript{2} and EGTA to 1 ml enzyme solution (0.4 mg ml\textsuperscript{-1}) in equimolar concentrations of 10 mM, and finally the change in absorbance at 280 nm was measured. The relative derivative absorption coefficient is the normalization of melting points calculated at each increasing temperature repeated twice with an error of 5%. The relative derivative absorption coefficients were calculated using the Agilent ChemStation for UV-Visible Spectroscopy software (Agilent Technologies, USA) as described by Dvortsov et al., [30]. A curve of relative derivative absorption coefficient versus temperature was plotted to display the melting profile of \textit{Ct43Araf} and \textit{CtG}H43.

Circular Dichroism Analysis of Truncated Catalytic Derivative \textit{CtG}H43

Far-UV Circular dichroism (CD) spectra of \textit{CtG}H43 were recorded on a spectropolarimeter (Jasco Corporation, Tokyo, JASCO J-815), equipped with a peltier system for temperature control at 25\degree C using a cell with a path length of 0.1 cm. The
spectral accumulation parameters were carried out using a scan-rate of 50 nm min⁻¹, a 1 nm bandwidth in the wavelength range of 195–250 nm with an average of six scans for each far-UV spectrum. The CD spectra of CtGH43 is presented in terms of mean residue ellipticity (MRE, expressed as deg cm² dmol⁻¹) as a function of wavelength, calculated following the procedure described earlier [31] using a protein concentration of 15 μM in 10 mM Tris-HCl, pH 7.5. The CD spectra were corrected for buffer contributions and secondary structures were calculated by using web based K2d neural network software package (http://www.ogic.ca/projects/K2d2/) as described by Perez-Iratxeta and Andrade-Navarro [32].

Results

Gene Amplification and Cloning

The family of 43 glycoside hydrolase (Ct43Araf) from C. thermocellum displays an N-terminal family 43 glycoside hydrolase catalytic module (CtGH43, 903 bp) followed by two successive carbohydrate binding modules (CBMs) CtCBM6A (405 bp) and CtCBM6B (402 bp) at the C-terminus [Fig. 1]. The DNA encoding Ct43Araf (GenBank Accession No: ABN52503.1 comprising modules CtGH43, CtCBM6A and CtCBM6B) and its truncated derivative (CtGH43) were PCR-amplified using oligonucleotide primers containing NheI (gctagc) and XhoI (ctcgag) restriction sites. The PCR-amplified DNA of Ct43Araf was digested with NheI-XhoI restriction enzyme. The digested fragment of Ct43Araf was cloned into NheI-XhoI digested pET-21a(+) expression vector, while PCR amplified and digested DNA of CtGH43 was cloned earlier in pET-28a(+) vector earlier [21], resulting in respective recombinant plasmids. The positive clones of Ct43Araf and CtGH43 were identified by restriction enzyme digestion. CtGH43 was amplified, cloned and expressed earlier and reported [21].

Expression and Purification of Recombinant Ct43Araf and CtGH43

After confirming the positive clones by restriction enzyme digestion, E. coli BL-21 (DE3) cells were transformed with recombinant plasmid of Ct43Araf. CtGH43 was transformed in E. coli BL-21 (DE3) pLysS cells [21]. The expression of recombinant proteins were analysed by SDS-PAGE. The His₆-tagged clostridial recombinant proteins were purified by immobilized metal ion affinity chromatography (IMAC) from the cell free extracts. The SDS-PAGE analysis of purified recombinant protein Ct43Araf is displayed in Fig. 2A. The recombinant protein Ct43Araf displayed molecular size of 63 kDa, whereas, CtGH43 showed a size of 34 kDa as reported previously [21]. The above recombinant proteins were expressed as soluble proteins. The ability of Ct43Araf and CtGH43 to hydrolyze the arabinose-containing polysaccharides was explored and compared.

Substrate Specificity and Kinetic Parameters of Recombinant Ct43Araf and CtGH43

Substrate specificity and kinetic parameters with natural substrates. The assays for natural substrates were carried out using the pH, buffers and other conditions as described in methods section. The activities of Ct43Araf and its truncated derivative CtGH43 with various polysaccharides are reported in Table 1. The maximum specific activity (U mg⁻¹) of Ct43Araf and CtGH43 were found to be 4.7 and 5.0, respectively, with rye arabinoxylan which was followed by the decreasing order of activities against wheat arabinoxylan, oat spelt xylan, beechwood xylan and birchwood xylan as illustrated in Table 1. Both the catalytic enzymes showed low activity (less than 1.0 Umg⁻¹) with arabinogalactan and rhamnogalactouronan (α-L-arabinopyranosyl side chain containing polysaccharides) [Table 1]. Ct43Araf and CtGH43 did not show any considerable increase in activity with 1,5-α-L-arabinobiose and 1,5-α-L-arabinotetraose (the enzymatically hydrolyzed de branched sugar beet araban) as compared to complex sugar beet araban which indicated that the above enzymes lack specificity for 1,5-α-L-arabinosyl linkages [Table 1]. The above results also indicated that both Ct43Araf and CtGH43 do not possess α-L-arabinanase type of activity. The kinetic properties and catalytic efficiency of both the enzymes were determined with the natural substrates [Table 2]. Ct43Araf and CtGH43 showed highest turnover number (kₐu) of 280 min⁻¹ and 298 min⁻¹, respectively, and also highest catalytic efficiency (kₐu/Kₘ) of 3.4×10⁴ and 3.6×10⁴ with rye arabinoxylan. Both the enzymes were able to act on insoluble wheat arabinoxylan showing catalytic efficiencies (kₐu/Kₘ) of 7.1×10⁵ min⁻¹ mg⁻¹ ml⁻¹ and 6.1×10⁵ min⁻¹ mg⁻¹ ml⁻¹ for Ct43Araf and CtGH43, respectively. The catalytic efficiencies (kₐu/Kₘ) observed with other soluble substrates like beechwood and birchwood xylans were found to be comparatively less.

Substrate specificity and kinetic parameters with synthetic substrates. The catalytic efficiencies (kₐu/Kₘ) of Ct43Araf and CtGH43 with pNP-α-L-arabinofuranoside (pNPA) were found to be 5.6×10⁵ min⁻¹ mg⁻¹ ml⁻¹ and 7.1×10⁵ min⁻¹ mg⁻¹ ml⁻¹, respectively, while with pNP-α-L-arabinopyranoside (pNPAp), the kₐu/Kₘ value for both the modules was 2.2×10⁵ min⁻¹ mg⁻¹ ml⁻¹ [Table 2]. Therefore, we can say that the Ct43Araf and CtGH43 were able to release p-nitrophenol from pNP-α-L-arabinofuranoside (pNPA) as well as from pNP-α-L-arabinopyranoside (pNPAp), but the catalytic efficiencies of both modules were approximately, 3-fold higher with pNPAp as compared to pNPA. Based on the catalytic efficiencies observed for Ct43Araf and CtGH43 with natural as well as synthetic substrates, it is evident that both these proteins are predominantly α-L-arabinofuranosidase.
Effects of Metal Ions and Chemical Agents on \(Ct43Araf\) and \(CtGH43\) Activity

The enzyme activities of \(Ct43Araf\) and \(CtGH43\) increased by more than 2-fold with \(Mg^{2+}\) and \(Ca^{2+}\) salts at low concentrations (5–10 mM) [Table 3]. A slight increase in activity of \(Ct43Araf\) and \(CtGH43\) were also observed with \(Ni^{2+}\) salts (15% and 47%), \(Mn^{2+}\) (20% and 21%) and \(Zn^{2+}\) (8% and 24%) salts [Table 3]. The enzyme activity of \(Ct43Araf\) and \(CtGH43\) were adversely affected at higher concentrations (20 mM) of \(Co^{2+}\) (75%) in both enzymes, \(Hg^{2+}\) (80% and 70%), \(Cu^{2+}\) (70% in both enzymes) and \(Ag^{+}\) (80% and 75%), respectively [Table 3]. The enzyme activity of both \(Ct43Araf\) and \(CtGH43\) decreased by more than 90% in presence of EDTA (10 mM) or 10 mM EGTA [Table 3]. The decrease in activity in presence of EGTA indicated that \(Ca^{2+}\) ions may be essential for enzyme activity as EGTA specifically binds and chelates calcium ions in 1:1 molar ratio [35]. The catalytic activity was noticeably increased in the presence of \(Ca^{2+}\) and \(Mg^{2+}\) salts elucidating the fact that these metal cations may be needed as co-factors while the heavy metals especially \(Co^{2+}\), \(Hg^{2+}\), \(Cu^{2+}\) and \(Ag^{+}\) caused decrease in enzyme activity as shown for recombinant cellulases [36,37].

TLC Analysis of Enzyme Reaction Products

The TLC analysis of the enzyme reaction products (sugars) indicated that \(Ct43Araf\) releases only arabinose from rye arabinoxylan, wheat arabinoxylan and oat spelt xylan [Fig. 3]. The similar results were obtained with beechwood xylan and insoluble wheat arabinoxylan (data not shown). The above result and the results obtained from the assays with \(\beta\)-NP-glycosides indicated that \(Ct43Araf\) could be \(\alpha\)-L-arabinofuranosidase since the above mentioned polysaccharides contain \(\alpha\)-L-arabinofuranosyl residues. The relative migration of \(Ct43Araf\)/hydrolyzed sugars with commercially available standards clearly indicated that \(\alpha\)-arabinose could possibly be the major sugar released as no spots for xylose was observed on the TLC plate [Fig. 3]. This was in agreement with the previous reports on \(\alpha\)-L-arabinofuranosidases [36].

HPAEC Analysis of Enzyme Reaction Products

The reaction products of \(Ct43Araf\) with rye arabinoxylan, wheat arabinoxylan (soluble) and oat spelt xylan analyzed by HPAEC showed only arabinose as the released sugar [Fig. 4]. \(L\)-Arabinose and \(D\)-xylose used as standards for the HPAEC analysis of enzyme-substrate reaction products showed peaks at 10.4 min and at 13.6 min, respectively [Fig. 4A and 4B]. The chromatograms of hydrolysis products (\(\alpha\)-arabinosyl, \(\beta\)-arabinosylxylo and oat spelt xylan) by both \(Ct43Araf\) and \(CtGH43\) showed only the peak corresponding to \(L\)-arabinose at 10.4 min and no peak for xylose was observed [Fig. 4C, 4D and 4E]. Based on HPAEC and TLC analysis and the results obtained with \(\beta\)-NP-glycosidase assays we can conclude that both \(Ct43Araf\) and \(CtGH43\) exhibit \(\alpha\)-L-arabinofuranosidase activity as also reported earlier [36]. The HPAEC analysis of the hydrolyzed products of \(\alpha\)-L-arabinofuranosidase \(Ct43Araf\) from \(C.\ thermocellum\) supported the observation that both the modules released \(L\)-arabinose from arabinoxylans.

Protein Melting-curve Analysis \(Ct43Araf\) and \(CtGH43\)

The recombinant protein \(Ct43Araf\) showed two separate melting peaks at 53°C and 78°C [Fig. 5A], whereas, \(CtGH43\) displayed a single melting peak at around 78°C [Fig. 5B]. This suggested that the peak at 53°C is associated with CBMs (CBM6A-CBM6B) and the peak at 78°C was due to \(CtGH43\). This type of melting curve indicated that \(CtGH43\) and non-catalytic CBMs (CBM6A-CBM6B) are melting independently [Fig. 5A]. The presence of \(Ca^{2+}\) ions (10 mM) caused significant changes in \(Ct43Araf\) as well as in \(CtGH43\) protein-melting profiles. The peak for \(CtGH43\) shifted towards higher temperature i.e. 83°C from 78°C but the peak for corresponding to CBMs (CBM6A-CBM6B) of \(Ct43Araf\) was masked in presence of \(Ca^{2+}\) ions [Fig. 5 A & 5B]. When EGTA salt was added (10 mM) to the enzyme-substrate reaction mixture containing \(Ca^{2+}\) (10 mM), there was shifting back of the melting peaks to the original temperature of 78°C of catalytic \(CtGH43\) as evident from Fig. 5 A & B (small dotted lines).

Structural Analysis of \(CtGH43\) by Circular Dichroism

The analysis of CD spectra of \(CtGH43\) for detecting the secondary structural elements was based on the previous reports of CD spectra analysis of proteins by Kelly et al. [31] which showed that it mostly contained \(\beta\)-sheets and random coils [Fig. 6]. The CD spectra \(CtGH43\) was analysed using K2d as described by Perez-Iratxeta and Andrade-Navarro, [32] revealed that it contains 48% \(\beta\)-sheets, 49% random coils and only 3% \(\alpha\)-helices [Table 4].

Discussion

In recent past, few family 43 glycoside hydrolases have been reported in the CAZY database (www.cazy.org) from \(C.\ thermocellum\) (galactanase), \(B.\ theitiamonax\) (\(\alpha\)-1,2-arabinofuranosidase), \(C.\ japonicas\) (\(\alpha\)-1,5-exoarabinanase) \(B.\ adolescentis\) (only other known arabinofuranosidase with ability to hydrolyze doubly substituted xylosyl) [6,9,13,14]. \(CtGH43\) unlike other member of the family 43 glycoside hydrolase showed significant homology with CBM6s from different bacterial sources [39]. The sequence and phylogenetic tree analysis of \(CtGH43\) has been reported by Ahmed et al., 2012 [39]. \(Ct43Araf\) and \(CtGH43\) showed maximum activity against rye arabinoxylan; however, significant activities were also observed with wheat arabinoxylan, oat spelt xylan, birchwood xylan and beech wood xylan. It has been previously reported that the rye arabinoxylans have nearly 50% of the xylose residues substituted at the terminal by \(L\)-arabinosine at O-5 and around 2% at both O-2 and O-3. This suggested that \(Ct43Araf\) displays \(\alpha\)-L-arabinofuranosidase type of activity in exo-acting manner similar to the previous report by Bengtsson et al. [4]. \(Ct43Araf\) and \(CtGH43\) also showed lesser but considerable activity with water soluble wheat arabinoxylan, which are rich in 2-mono and di-substituted xyloses and low in 3-mono and di-substituted xylose [4,6,9], indicating that they also act at O-2 substituted xylose. Further, \(Ct43Araf\) and \(CtGH43\) displayed noticeable activities with beechwood and birchwood xyloans comprising of O-2 and O-3 substituted xylose. The above observations and previous report by Bourgois et al. [12] indicated that both the recombinant enzymes have the ability to catalyze the hydrolysis of terminal non-reducing \(\alpha\)-L,1-2- as well as \(\alpha\)-L,1-3- arabinosyl residues in exo-acting manner. The activity with oat spelt xylan can be attributed to the presence of arabinose (10%, w/v). The low activity with arabinogalactan and rhamnogalactouronan was mainly due to the fact that similar to \(\beta\)-1,4-xylopyranose, the \(\beta\)-1,4-galactans too, are poorly substituted with \(\alpha\)-L-arabinopyranosyl side-chains as reported by Obro et al. [8]. Therefore, we can conclude that enzymes (\(Ct43Araf\) and \(CtGH43\)) acted mainly on the glycosidic linkage of \(\alpha\)-arabinofuranosyl substituted to the main chain \(\beta\)-1,4-xylose occurring predominantly in the arabinoxylans. Both \(Ct43Araf\) and \(CtGH43\) were able to act on and degrade synthetic substrates \(\beta\)-NP-\(\alpha\)-L-arabinofuranoside as well as \(\beta\)-NP-\(\alpha\)-L-arabi-
novopyranoside. Both C43Araf and CGGH3 showed high catalytic efficiencies against β-NPαf and βNPAf, elucidating their bi-functional nature. But close inspection of catalytic efficiency data revealed that C43Araf is primarily α-L-arabinofuranosidase as the kcat/Km was 3-fold higher in case of βNPAf as compared to βNPAf.

The enzyme activity of C43Araf and CGGH3 increased significantly by more than two-fold in presence of Ca²⁺ and Mg²⁺ salts, implying that these ions are needed as cofactors. However, the enzyme activity was unaffected by lower concentrations of Ca²⁺, Co²⁺, Hg²⁺ or Ag⁺ ions but it decreased at higher concentrations. The enzyme activity of C43Araf and CGGH3 decreased sharply in the presence of EGTA. This implied that Ca²⁺ ions might be involved in the catalysis and imparting stability to the structures of C43Araf and CGGH3. A few recombinant family 43 glycoside hydrolases have been reported in the past by Sancis et al., [40], Morais et al., [41] and Jordan et al., [42] which showed enhanced enzyme activity in the presence of Ca²⁺ ions.

The TLC and HPAEC analyses indicated that both C43Araf and CGGH3 released L-arabinose side chain sugars from arabinoxylans. The TLC analysis of the hydrolysis products of rye arabinoxylan, wheat arabinoxylan and oat spelt xylan with C43Araf indicated that L-arabinose is the only monosaccharide released after the hydrolysis. However, close inspection of the TLC and HPAEC results combined with the results obtained with synthetic βNP-glycosides confirmed that both C43Araf and CGGH3 are predominantly α-L-arabinofuranosidase since both showed higher catalytic efficiency with βNPαf.

Protein-melting curves of C43Araf and CGGH3 showed that the CGGH3 and CBMs (CBM6A-CBM6B) melted independently of each other. The protein-melting peaks of CGGH3 and CBMs shifted to higher temperature in the presence of Ca²⁺ ions. However, on addition of equimolar concentration of EGTA and Ca²⁺ ions to the solutions of C43Araf and CGGH3, the melting temperature peaks were shifted back to the original positions. The presence of Ca²⁺ ions stabilized both the CBMs and CGGH3 module and prevented unfolding or denaturation. This enhanced stability of the CBM modules is observed through the absence of a 53°C denaturation event. Similar observations were also reported with a β-1,3-glucanase and associated CBM14 module [30]. The independent melting of protein modules was deduced by comparing with the previously reported melting profile of protein modules [30,43]. The shifting back of melting peaks in the presence of EGTA can be explained by the highly specific chelation of calcium ions by EGTA, making them unavailable to stabilize the enzyme CBM modules.

The CD analysis confirmed the fact that β-sheets and random coils were the main secondary structural elements present in the recombinant protein CGGH3. Only 3% α-helices were present in the CGGH3 structure. The results of CD analysis of CGGH3 were in agreement with the secondary structure prediction of the same protein using PSIPRED VIEW software [44] with slight difference in number of α-helices [Table 4]. However, it is important to consider that the presence of aromatic residues can significantly affect the far-UV CD spectrum of peptides as reported by Pace and Scholtz [45] and Fujiwara et al., [46]. Such interactions sometimes could produce a significant increase in the helical population.

Conclusions

The C43Araf and its truncated derivative CGGH3 possess α-L-arabinofuranosidase type of activity as analyzed by βNP-glycoside based assays, TLC and HPAEC analysis. The presence of CBMs did not affect the α-L-arabinofuranosidase activity of C43Araf and CGGH3. The enzyme activity of both C43Araf and CGGH3 was significantly enhanced in the presence of Ca²⁺ and Mg²⁺ salts. C43Araf and CGGH3 showed ability to degrade both β-nitrophenol-α-L-arabinofuranoside and β-nitrophenol-α-L-arabinopyranoside. The presence of Ca²⁺ ions imparted thermal stability to both the enzymes. The circular dichroism analysis of CGGH3 showed that it is mostly composed of β-sheets and random coils.
