Abstract: A mixture of 2-pyridine carboxaldehyde, 4-formylimidazole (or 2-methyl-4-formylimidazole), and NiCl₂·6H₂O in a molar ratio of 2:2:1 was reacted with two equivalents of hydrazine monohydrate in methanol, followed by the addition of aqueous NH₄PF₆ solution, afforded a NiII complex with two unsymmetric azine-based ligands, [Ni(HL₁)₂(PF₆)₂] (1) or [Ni(HL₂Me)₂(PF₆)₂] (2), in a high yield, where HL₁ denotes 2-pyridymethylidenehydrazono-(4-imidazolyl)methane and HL₂Me is its 2-methyl-4-imidazolyl derivative. The spectroscopic measurements and elemental analysis confirmed the phase purity of the bulk products, and the single-crystal X-ray analysis revealed the molecular and crystal structures of the NiII complexes bearing an unsymmetric HL₁ or HL₂Me azines in a tridentate κ³ N, N', N'' coordination mode. The HL₁ complex with a methanol solvent, 1-MeOH, crystallizes in the orthorhombic non-centrosymmetric space group P2₁2₁2₁ with Z = 4, affording conglomerate crystals, while the HL₂Me complex, 2-H₂O·Et₂O, crystallizes in the monoclinic and centrosymmetric space group P2₁/n with Z = 4. In the crystal of 2·H₂O·Et₂O, there is intermolecular hydrogen-bonding interaction between the imidazole N–H and the neighboring uncoordinated azine-N atom, forming a one-dimensional polymeric structure, but there is no obvious magnetic interaction among the intra- and interchain paramagnetic NiII ions.

Keywords: (pyridyl)(imidazolyl)azines; aldazines; kryptoracemate; crystal structure

1. Introduction

Azines are a class of organic molecules with diimine functionality, R¹R²C=N–N=CR³R⁴, which are often regarded as analogs of 1,3-butadiene (R¹R²C=CH–CH=CR³R⁴) due to the resemblance and similarity in their functional groups [1,2], and represent a well-known class of compounds with interesting chemical properties [3] and applications in several and diverse fields [2]. In the area of synthetic organic chemistry, they serve as excellent synths for obtaining heterocyclic compounds such as purines, pyrazoles, and pyrimidines by undergoing [2,3] cross-cycloaddition in the presence of dienophiles [4–6]. They are good pharmaceutical and biological agents, for example, antimalarial, anticonvulsant, and antioxidant properties [7–10]. In the agricultural field, azines exhibit herbicidal properties [11,12]. Azine-based polymers are successfully used for chemosensors [13–15] and they also possess promising cathodic abilities for organic batteries [16–18] and could be also employed for 2D field effect transistors in their crystallized phase as silicon [19]. Some azine-based polymers possess promising cathodic abilities for organic batteries and are vital in optoelectronic devices. Furthermore, compounds containing the diimine (C=N–N=C) linkers have been investigated as highly luminescent frameworks [20–22] as well as good photosensitizers in solar cells [23].

The coordinating ability of the diimine group in the azines is interesting due to the flexibility of the N–N bond. A series of transition-metal complexes of azine-based ligands, which possess interesting structural motifs and other properties, have been reported [2,24].
Pyridyl ketazine is one of the unique azine-based ligands that have been explored by several researchers for its coordinating abilities and modes, thus paving way for the investigation of several azine-based ligands for their unique coordination chemistry [25–27]. Our previous studies reported a series of mono- and dinuclear iron(II) complexes with imidazole-4-carbaldehyde azine and other imidazole groups as azine ligands showcasing different modes of coordination towards the iron(II) in the various complexes [28–30].

Recently, we have investigated the chemistry of pyridyl and imidazolyl azine-based ligands, where an unprecedented selective synthesis of the unsymmetric (2-pyridyl)(2-methyl-4-imidazolyl)azine is obtained in an excellent yield with an interesting bonding mode [30]. Pursuing our interest in the unsymmetric azine-based ligand, we attempted to synthesize the corresponding nickel(II) complexes bearing 2-pyridylmethylidenehydrazone-(4-imidazolyl)methane (HL\textsuperscript{H}) and 2-pyridylmethylidenehydrazone-(2-methyl-4-imidazolyl) methane (HL\textsuperscript{Me}).

2. Results and Discussion

2.1. Preparation of Unsymmetric (2-Pyridyl)(4-Imidazolyl)azines and Their Nickel(II) Complexes

The most intuitive and possibly simplest method for preparation of an unsymmetric (2-pyridyl)(4-imidazolyl)azine is a reaction of stoichiometric amounts of 2-pyridinecarboxaldehyde, 1H-imidazole-4-carboxaldehyde (or its 2-methyl derivative), and hydrazine (Scheme 1) [31,32]. However, as was expected, all attempts to prepare the compounds HL\textsuperscript{R} with this method failed to isolate the desired compounds, because the reaction gave a complicated mixture of the products (Figure S1 in the Supplementary Materials) which were hard to be separated by any purification method. In a previous study [30], we serendipitously found that the reaction in the presence of iron(II) salts gave selectively the crystals of a Fe\textsuperscript{II} complex bearing unsymmetric azine, [Fe(HL\textsuperscript{Me})\textsubscript{2}](PF\textsubscript{6})\textsubscript{2}·1.5H\textsubscript{2}O. To clarify the role of transition-metal salts in the selective formation of a certain complex, we used a nickel(II) chloride for the preparation of (2-pyridyl)(4-imidazolyl)azine complexes.

![Scheme 1. Preparation of (2-pyridyl and/or 4-imidazolyl)azine compounds.](image)

A mixture of 2-pyridine carboxaldehyde, 4-formylimidazole (or 2-methyl-4-formylimidazole), and NiCl\textsubscript{2}·6H\textsubscript{2}O in a 2:2:1 molar ratio in methanol was reacted with a stoichiometric amount of hydrazine monohydrate, followed by the addition of an aqueous solution of NH\textsubscript{4}PF\textsubscript{6}, which gave an obvious color change of the reaction solution to deep reddish orange. From the reaction mixture, air-stable deep reddish orange crude product (1 from 4-formylimidazolylazo or 2 from the 2-methyl derivative) was obtained by evaporation of the solvent in a relatively high yield (80% and 83% for compounds 1 and 2, respectively). The crude products are soluble in common polar organic solvents and recrystallized from acetonitrile by vapor diffusion of methanol to deposit block-shaped deep reddish orange crystals of 1·MeOH. For compound 2, platelet single-crystals of 2·H\textsubscript{2}O-Et\textsubscript{2}O suitable for X-ray diffraction study were deposited by vapor diffusion of diethyl ether into a methanol solution. In the FT-IR measurement of both compounds, the crude and recrystallized products gave almost identical spectra, which showed ν(C=N) stretching bands at 1619
and 1603 cm\(^{-1}\) for 1 and 1625 and 1603 cm\(^{-1}\) for 2 (Figure S2). This suggests that like the above-mentioned Fe\(^{II}\) complex [30], a certain Ni\(^{II}\) complex was selectively formed among several possible products. The elemental analyses of the vacuum-dried (partially efflorescent) samples suggested the empirical composition of [Ni(HL\(^{1}\))\(_2\)][PF\(_6\)]\(_2\)-0.5MeOH and [Ni(HL\(^{1}\))\(_2\)][PF\(_6\)]\(_2\) MeCN·1.5MeOH for 1 and 2, respectively.

The \(\chi_M T\) values of 1 and 2 at 300 K are 1.14 and 1.21 cm\(^3\) K mol\(^{-1}\), respectively. These values are almost constant down to 20 K, then, decrease sharply below 20 K due to magnetic anisotropies of them (Figure S3). No significant magnetic interactions between complex cations were observed. In addition, magnetizations at 1.9 K for both complexes (Figure S3) did not reach the saturation values at 5 T, indicating the existence of magnetic anisotropies for both complexes. They are common behavior for magnetically isolated octahedral mononuclear nickel(II) complexes.

Absorption spectra of complexes 1 and 2 recorded in acetonitrile at room temperature were shown in Figure S4. Both complexes displayed two absorption bands in the region (Figure S3) did not reach the saturation values at 5 T, indicating the existence of magnetic anisotropies for both complexes. They are common behavior for magnetically isolated octahedral mononuclear nickel(II) complexes.

2.2. Crystal Structures of the Nickel(II) Complexes

The molecular and crystal structures of 1-MeOH and 2-H\(_2\)O-Et\(_2\)O was confirmed by the single-crystal X-ray analysis at 188(2) K. Compound 1-MeOH crystallized in the orthorhombic system and a non-centrosymmetric space group \(P2_12_12_1\) with \(Z = 4\) (Table 1), indicating conglomerate crystallization (spontaneous resolution of the enantiomers). The asymmetric unit consists of one [Ni(HL\(^{1}\))\(_2\)]\(^{2+}\) cation, two PF\(_6\)\(^{-}\) anions, and a methanol molecule of crystallization. An ORTEP drawing of 1 is shown in Figure 1. The Ni\(^{II}\) center was coordinated by two HL\(^{1}\) ligands in a pseudo-octahedral coordination geometry. Each HL\(^{1}\) ligand has an E,Z configuration (mode (i) in Scheme 2) serving as tridentate coordination to a Ni\(^{II}\) center in a meridional fashion via pyridyl-N, imidazolyl-N, and one of the azine-N atoms close to the pyridyl substitution group. This coordination mode forms a five-membered chelate ring on the pyridine side and a six-membered one on the imidazole side. It is noted that the other azine-N atom remains uncoordinated and the imidazole-NH group remains protonated.

Figure 1. An ORTEP drawing of [Ni(HL H)2](PF6)2·MeOH (1·MeOH) with an atom-numbering scheme (ellipsoids are drawing at a 50% probability level).

The coordination bond lengths and angles of 1 are summarized in Table 2, which indicates the nearly ideal octahedral coordination geometry around the Ni center, with minor deviations. The Ni–N bond lengths are in the range of 2.039(5)–2.095(5) Å, which are typical for NiII-N(imine) coordination bonds [33,34]. The five-membered chelate bite angles (N1–Ni1–N2 and N6–Ni1–N7) are smaller by ca. 10° than the six-membered chelate bite angles (N2–Ni1–N5, N7–Ni1–N10), as expected. The mutually trans bond angle of N2–Ni1–N7 for the azine-N donors (175.7(2)°) is close to the ideal value.

The packing structure of 1·MeOH was illustrated in Figure S5. In the crystal structure, an explicit hydrogen-bond was observed between one of the imidazole N–H group and the O atom of the methanol molecule of crystallization: N9(–H)···O1 2.710(8) Å (Figure 1), but no other intermolecular interactions were found. In a previous study, we reported the crystal structure of the analogous FeII complex, [Fe(HLMe)2](PF6)2·1.5H2O [30], in which a noble kryptoracemate resulted from a formation of a one-dimensional helical polymer by an intermolecular hydrogen-bonding interaction. In the present NiII complex 1·MeOH, although the compound was crystallized in a non-enantiogenic (Sohncke) space group, P212121, the complex cation was crystallized in a discrete form (Figure S5) and did not show
the kryptoracemate phenomenon. We have tried to measure the solid-state CD spectra of a piece of single-crystal of 1·MeOH (in a KBr disk), but no CD signal was observed.

Table 2. Selected bond lengths (Å) and angles (°) around the NiII center in compounds 1·MeOH and 2·H2O·Et2O.

| Compound | 1·MeOH | 2·H2O·Et2O |
|----------|--------|------------|
| Ni1–N1, Ni–N6 | 2.094(4), 2.095(5) | 2.110(4), 2.126(4) |
| Ni1–N2, Ni–N7 | 2.084(4), 2.082(4) | 2.078(4), 2.093(4) |
| Ni1–N5, Ni–N10 | 2.047(5), 2.039(5) | 2.068(4), 2.065(4) |
| N1–Ni1–N2, N6–Ni1–N7 | 79.22(19), 78.55(19) | 78.80(16), 78.94(17) |
| N2–Ni1–N5, N7–Ni1–N10 | 87.99(18), 88.63(19) | 88.95(16), 89.00(16) |
| N1–Ni1–N5, N6–Ni1–N10 | 167.20(18), 166.57(18) | 166.81(16), 167.93(16) |
| N1–Ni1–N6, N5–Ni1–N10 | 88.85(18), 91.3(2) | 91.91(18), 89.59(16) |
| N2–Ni1–N7 | 175.74(19) | 165.77(16) |
| N1–Ni1–N7, N2–Ni1–N6 | 99.83(19), 97.26(17) | 90.25(15), 92.25(16) |
| N1–Ni1–N10, N5–Ni1–N6 | 89.45(19), 93.27(19) | 87.64(16), 93.46(16) |
| N2–Ni1–N10, N5–Ni1–N7 | 95.50(19), 92.97(19) | 99.48(16), 102.60(16) |

The compound, 2·H2O·Et2O, crystallized in the monoclinic system and centrosymmetric space group $P2_1/n$ with $Z = 4$ (Table 1). The molecular structure of the NiII complex cation in 2 (Figure 2) is very similar to that in 1, except for the large deviation of the bond angles, e.g., N2–Ni1–N7 and N5–Ni1–N7 (Table 2), which resulted from steric congestion from the substituted methyl group at the imidazole ring.

Figure 2. An ORTEP drawing of the complex cation [Ni(HLMe)$_2$]$^{2+}$ in 2·H2O·Et2O with an atom-numbering scheme (ellipsoids are drawing at a 30% probability level).

In the crystal structure, the intermolecular hydrogen-bonding interaction was observed between the imidazole N–H and azine-N groups: N9(–H9)···N8 2.714(6) Å, forming one-dimensional coordination polymers (Figure 3). In contrast to the corresponding FeII complex [30], this NiII complex 2·H2O·Et2O crystallized in a centrosymmetric space group $P2_1/n$, indicating the crystal consists of the racemic mixture.
Figure 2. An ORTEP drawing of the complex cation \([\text{Ni}(\text{HLMe})_2]^2+\) in 2·H₂O·Et₂O with an atom-numbering scheme (ellipsoids are drawing at a 30% probability level).

In the crystal structure, the intermolecular hydrogen-bonding interaction was observed between the imidazole N–H and azine-N groups: N9(–H9)···N8 2.714(6) Å, forming one-dimensional coordination polymers (Figure 3). In contrast to the corresponding Fe II complex \([30]\), this NiII complex 2·H₂O·Et₂O crystallized in a centrosymmetric space group \(P\)21/n, indicating the crystal consists of the racemic mixture.

Figure 3. Intermolecular hydrogen-bonding interaction gives a one-dimensional polymer chain in 2·H₂O·Et₂O. Color code: Ni, teal; P orange; F, yellow-green; N, blue; C, gray; H, silver.

3. Materials and Methods

3.1. Chemicals and Physical Methods

All chemicals and solvents used for syntheses of azine compounds and Ni complexes were reagent grade and used without further purification. First, 2-pyridinecarboxaldehyde, 1H-imidazole-4-carboxaldehyde, 2-methyl-1H-imidazole-4-carboxaldehyde, nickel(II) chloride hexahydrate, and ammonium hexafluorophosphate were purchased from FUJIFILM (Tokyo, Japan). All reactions were carried out under aerobic conditions. Infrared spectra (KBr pellets; 4000–400 cm\(^{-1}\)) were recorded on a JASCO FT-001 Fourier transform infrared spectrometer (JASCO, Tokyo, Japan). Absorption spectra were recorded on a Shimadzu UV/Vis-1650 spectrophotometer (Kyoto, Japan) in the range of 200–600 nm at room temperature in acetonitrile. The \(^1\)H NMR spectra were acquired on a Varian 400-MR spectrometer (Los Angeles, CA, USA); the chemical shifts were referenced to residual \(^1\)H NMR signals of solvents and are reported versus TMS. Elemental analyses were conducted at Advanced Science Research Center, Okayama University. Magnetic susceptibilities were measured on a Quantum Design MPMS XL5 SQUID magnetometer (Tokyo, Japan) in a 1.9–300 K temperature range under an applied magnetic field of 0.1 T at the Okayama University of Science. Corrections for diamagnetism were applied using Pascal’s constants \([35]\).

3.2. Preparation of Nickel(II) Complexes

3.2.1. [Ni(\text{HL}^\text{I})_2]\text{[PF}_6\text{]}_2 (I)

A methanol solution (30 mL) of NiCl\(_2\)-6H\(_2\)O (0.477 g, 2.00 mmol) was added to a methanol solution (60 mL) containing 2-pyridinecarboxaldehyde (0.432 g, 4.00 mmol) and 1H-imidazole-4-carboxaldehyde (0.387 g, 4.00 mmol), followed by additions of hydrazine monohydrate (0.207 g, 4.00 mmol) in methanol (30 mL) and NH\(_4\)PF\(_6\) (0.652 g, 4.00 mmol) in water (20 mL). The mixture was stirred at ca. 60 °C for 3 h. The resulting solution was concentrated by a rotary vacuum evaporator to give a deep reddish-orange precipitate. The crude product was dissolved in methanol and acetonitrile and recrystallized by slow evaporation to deposit deep reddish-orange microcrystals. Crystals suitable for the SC-XRD study were obtained from a mixture of acetonitrile and methanol. Yield: 1.72 g (80%). Anal. Found: C, 32.41; H, 2.36; N, 18.38%. Calcd for C\(_{20.5}\)H\(_{20}\)F\(_2\)NiN\(_{10}\)O\(_{0.5}\)P\(_2\) (for 1·0.5MeOH: C, 32.27; H, 2.64; N, 18.36%). IR (KBr pellet): \(\nu\)C=\(\text{N}\) (imine) 1619, 1603 cm\(^{-1}\); \(\nu\)P–F (PF\(_6^-\)) 840 cm\(^{-1}\).
3.2.2. [Ni(HL\text{Me})_2](PF_6)_2 (2)

Complex 2 was obtained in a similar manner using 2-methyl-1H-imidazole-4-carboxaldehyde instead of 1H-imidazole-4-carboxaldehyde. Yield: 83%. Anal. Found: C, 35.45; H, 3.43; N, 17.95%. Calcd for C_{25}H_{33}F_{12}NiO_{1.5}F_2 (for 2·CH_3CN·1.5CH_2OH: C, 35.44; H, 3.62; N, 17.83. IR (KBr pellet cm\(^{-1}\)); \nu_{C=N} (imine) 1635, 1609 (fs) \nu_{P-F} (PF_6^-) 845(s). Deep reddish-orange platelet crystals (2·H_2O·Et_2O) suitable for SC-XRD were obtained from a mixture of methanol and diethyl ether.

3.3. Structure Determination by X-ray Crystallography

The single-crystal X-ray diffraction data for compounds 1·MeOH and 2·H_2O·Et_2O were collected at 188(2) K using a Rigaku RAXIS RAPID II imaging plate area detector employing graphite monochromated Mo K\(\alpha\) radiation (\(\lambda = 0.71073\) Å). The structures were solved by the direct method, employing the SIR2014 software packages [36], and refined on \(F^2\) by full-matrix least-squares techniques using the SHELXL2014 program package [37]. All non-hydrogen atoms were refined anisotropically, and hydrogen atoms were included in the calculations with riding models. All calculations were performed using the Crystal Structure software package [38]. The crystal parameters, data collection procedure, and refinement results for the two compounds 1·MeOH and 2·H_2O·Et_2O are summarized in Table 1.

4. Conclusions

In this study, we attempted to prepare transition-metal(II) complexes of an unsymmetrical azine-type ligand, HL\text{R}, having 2-pyridyl and (2-methyl-)1H-imidazol-4-yl substituent groups. The desired azine could not be isolated in pure form from a simple stoichiometric reaction of hydrazine and respective aldehydes. However, in our previous study using Fe\(^{II}\) salts, a highly selective formation of [Fe(HL\text{Me})_2](PF_6)_2·1.5H_2O was observed, and the complex was found to be a kryptoracemate as a result of a one-dimensional helical chain structure by hydrogen-bonding interaction. At present, we have studied another two cases with nickel(II) salts: [Ni(HL\text{H})_2](PF_6)_2·MeOH (1·MeOH) and [Ni(HL\text{Me})_2](PF_6)_2·H_2O·Et_2O (2·H_2O·Et_2O). In both cases, a highly selective formation of the unsymmetrical azine complex was observed among other possible symmetrical and/or unsymmetrical complexes.

In the crystal of 1·MeOH, the compound was crystallized in a non-enantiogenic (Sohncke) space group, \(P2_12_12_1\), but the complex cation, [Ni(HL\text{H})_2]\text{2+}, was only hydrogen-bonded to the solvated methanol molecule. In the crystal structure of 2·H_2O·Et_2O, there observed a one-dimensional hydrogen-bonded polymer chain made from [Ni(HL\text{Me})_2]\text{2+}, but it was crystallized in a centrosymmetric space group, \(P2_1/c\). Thus, it can be concluded that the reason for the selective formation of an unsymmetric azine ligand in [Fe(HL\text{Me})_2](PF_6)_2·1.5H_2O was not solely the formation of the characteristic hydrogen-bonded chain. The suitable tridentate chelate formation of \(E,Z\)-HL\text{R} with mode (i) (in Scheme 2), which gives a five-membered chelate ring at the pyridyl coordination site and a six-membered chelate ring at the imidazolyl one, would probably be the most stable among the other coordination modes of symmetrical and unsymmetrical azine derivatives.
