Abstract

Using bosonization and path integral methods, we study general low temperature behavior of non-magnetic and magnetic impurity scattering in Tomonaga-Luttinger liquid, and calculate electron Green function for a general backward scattering potential. We demonstrate that electron density of state near the impurity site is suppressed by the backward scattering, but it mainly remains invariant as far away from the impurity, and at zero temperature the electrons are completely reflected on the impurity site, the system breaks into two subsystems but right- and left-moving electron fields have a twisted boundary condition. We also show that a testing charge can only be partially screened by conduction electrons, and in strong interaction region the impurity susceptibility has a $1/T$-type low temperature behavior.

I. INTRODUCTION

Recently, considerable efforts have been directed towards the study of the Fermi edge singularity [1–7], the Kondo effect [8–11] and the transport properties of one-dimensional (1D) Tomonaga-Luttinger (TL)-liquids [12–20]. The common property of a magnetic and a non-magnetic impurity scattering in TL-liquid is that there exists backward scattering of electrons on impurity, which drastically influences the low energy behavior of the system. The rigorous treatment of the backward scattering is a hard work because in low energy limit the backward scattering potential is renormalized to infinity, usual perturbation expansion method cannot be directly used. Just as shown in Ref. [12], for a repulsive interacting electronic system, in the low energy limit, the conduction electrons are completely reflected on the impurity site due to the backward scattering, the system breaks into two subsystems. Under this consideration, the authors in Ref. [21,22] studied the low energy behavior of a TL-liquid with an open boundary condition $\psi_{R\sigma}(x) = \pm \psi_{L\sigma}(-x)$, and obtained some results which are consistent with renormalization group calculation [12]. The backward scattering also drastically changes the Fermi edge singularity [3–7], which contributes a finite quantity to the exponent of the X-ray absorption line shape function, although between Refs. [3–6] and Ref. [7] there exists some controversy about the contribution size to this exponent by the backward scattering term. Although the topics has been extensively studied, there are still some hot debating theoretically about that whether is the electron’s density of state enhanced or suppressed near and far away from the impurity site? whether does the system break into two subsystems at the impurity site with the boundary condition $\psi_{R\sigma}(x) = \pm \psi_{L\sigma}(-x)$ in low energy limit? and so on. Due to the backward scattering term is relevant, we need a method rigorously to treat it. In this paper, using an elementary method which can rigorously treat the backward scattering term, we try to clarify these debating points.

In sections II and III, we consider non-magnetic and magnetic impurity scattering, respectively. Using an unitary transformation, we can eliminate the backward scattering
term (for magnetic impurity, the $Jz^2k_F$-term), and incorporate its influence on the system into electron interaction terms. In section IV, combining bosonization and path integral methods, we exactly calculate the Green functions of electrons $\tilde{\psi}_{R(L)\sigma}(x)$ and fermions $\tilde{\psi}_{1(2)\sigma}(x)$ for generally backward scattering, and show that the density of state of electrons near the impurity is suppressed by the backward scattering, while the electron density of state far away from the impurity remains intact. In section V, we show that at zero temperature electrons are completely reflected on the impurity, the system breaks into two subsystems but the electron fields have a twisted boundary condition. We calculate the exponent of Fermi-edge singularity function of X-ray absorption in section VI. In sections VII and VIII, we show that a testing charge is only partially screened by the conduction electrons, and study the low temperature behavior of impurity susceptibility, respectively. We give our conclusion and some discussion in section IX.

II. A NON-MAGNETIC IMPURITY SCATTERING

We consider the following impurity scattering in a general one-dimensional interacting electron system

$$H_T = H + H_{im}$$

$$H = -i\hbar v_F \sum_\sigma \int dx [\psi_{R\sigma}^\dagger(x)\partial_x \psi_{R\sigma}(x) - \psi_{L\sigma}^\dagger(x)\partial_x \psi_{L\sigma}(x)]$$

$$+ V_1 \sum_\sigma \int dx \rho_{R\sigma}(x)\rho_{L\sigma}(x) + V_2 \sum_\sigma \int dx \rho_{R\sigma}(x)\rho_{L-\sigma}(x)$$

$$H_{im} = \sum_\sigma V_{2k_F}[\psi_{R\sigma}^\dagger(0)\psi_{L\sigma}(0) + \psi_{L\sigma}^\dagger(0)\psi_{R\sigma}(0)]$$

where $\psi_{R\sigma}(x)$ and $\psi_{R\sigma}^\dagger(x)$ are the annihilation and creation field operators of the electrons with spin $\sigma$ that propagate to the right with wave vectors $\sim +k_F$, $\psi_{L\sigma}(x)$ and $\psi_{L\sigma}^\dagger(x)$ are the annihilation and creation field operators of left propagating electrons with spin $\sigma$ and wave vectors $\sim -k_F$; $\rho_{R(L)\sigma}(x) = \psi_{R(L)\sigma}^\dagger(x)\psi_{R(L)\sigma}(x)$ are the electron density operators; the spectrum of the electrons is linearized near the Fermi points and $v_F$ is the Fermi velocity. $V_{2k_F} = V(k = 2k_F)$ is the backward scattering potential of an impurity at $x = 0$ on
the conduction electrons. For simplicity we have omitted the forward scattering potential because it is trivial in our following transformations. In the bosonic representation of the electron fields $[24, 26]$, \( \psi_{R(\sigma)}(x) = (\frac{D}{2\pi \hbar v_F})^{1/2} \exp\{-i \Phi_{R(\sigma)}(x)\} \), where \( D \) is the band width of the conduction electrons (for simplicity we have neglected the factors \( \exp\{\pm i k_F x\} \)), the Hamiltonian \( H \) can be written as a diagonal form

\[
H = \frac{\hbar v_c}{4\pi} \int dx \left\{ \frac{1}{g_c} [\partial_x \Phi_- (x)]^2 + g_c [\partial_x \Phi_+ (x)]^2 \right\}
+ \frac{\hbar v_s}{4\pi} \int dx \left\{ \frac{1}{g_s} [\partial_x \Phi_- (x)]^2 + g_s [\partial_x \Phi_+ (x)]^2 \right\}
\]

where, \( v_c = v_F (1 - \gamma_c^2)^{1/2} \), \( v_s = v_F (1 - \gamma_s^2)^{1/2} \), \( \gamma_c = \frac{V_1 + V_2}{2\pi \hbar v_F} \), \( \gamma_s = \frac{V_1 - V_2}{2\pi \hbar v_F} \), \( g_c = (\frac{1-\gamma_c}{1+\gamma_c})^{1/2} \), \( g_s = (\frac{1+\gamma_s}{1-\gamma_s})^{1/2} \), \( \Phi_{\pm \sigma} (x) = \frac{1}{2} [\Phi_{\pm \uparrow} (x) + \Phi_{\pm \downarrow} (x)] \), \( \Phi_{\pm \sigma} (x) = \frac{1}{2} [\Phi_{\pm \uparrow} (x) - \Phi_{\pm \downarrow} (x)] \), \( \Phi_{R(\sigma)} (x) \pm \Phi_{L(\sigma)} (x) \). The impurity scattering term can be written

\[
H_{im} = \frac{2D}{\pi \hbar v_F} V_{2k_F} \cos[\Phi_- (0)] \cos[\Phi_- (0)]
\]

which has a conformal dimension \((g_c + g_s)/2\). For the repulsive electron-electron interactions with \( V_1 \geq V_2 \), the dimensionless coupling strength parameters \( g_c \) and \( g_s \) are less than one, the backward scattering term therefore is relevant, in the low energy limit, \( V_{2k_F} \) is renormalized to be infinity \([12]\), usual perturbation expansion of \( V_{2k_F} \) is invalid.

In order effectively to study the physical property of the system, we define a set of new fermion field operators to diagonalize the Hamiltonian \( H_{im} \)

\[
\psi_{1\sigma} (x) = \frac{1}{\sqrt{2}}(\psi_{Ra} (x) + \psi_{La} (x)) \quad \psi_{2\sigma} (x) = \frac{1}{\sqrt{2}}(\psi_{Ra} (x) - \psi_{La} (x))
\]

It is easy to check that the operators \( \psi_{1(2)\sigma} (x) \) satisfy the standard anticommutation relations. In terms of these new fermion fields \( \psi_{1(2)\sigma} (x) \), the Hamiltonian (1) can be written as

\[
H_1 = -i \hbar v_F \sum_\sigma \int dx [\psi_{1\sigma}^\dagger (x) \partial_x \psi_{1\sigma} (x) + \psi_{2\sigma}^\dagger (x) \partial_x \psi_{2\sigma} (x)]
+ \frac{V_1}{4} \sum_\sigma \int dx [\rho_{1\sigma} (x) + \rho_{2\sigma} (x)] [\rho_{1\sigma} (-x) + \rho_{2\sigma} (-x)]
+ \frac{V_2}{4} \sum_\sigma \int dx [\rho_{1\sigma} (x) + \rho_{2\sigma} (x)] [\rho_{1\sigma} (-x) + \rho_{2\sigma} (-x)]
\]
\[ H_2 = -\frac{V_1}{4} \sum_{\sigma} \int dx [\psi_{1,\sigma}^\dagger(x)\psi_{2,\sigma}(x) + h.c.] \left[ \psi_{1,\sigma}^\dagger(-x)\psi_{2,\sigma}(-x) + h.c. \right] \] (5)

\[ -\frac{V_2}{4} \sum_{\sigma} \int dx [\psi_{1,\sigma}^\dagger(x)\psi_{2,\sigma}(x) + h.c.] \left[ \psi_{1,-\sigma}^\dagger(-x)\psi_{2,-\sigma}(-x) + h.c. \right] \]

\[ H_{im} = \sum_{\sigma} V_{2k_F}[\rho_{1,\sigma}(0) - \rho_{2,\sigma}(0)] \]

where, \( H = H_1 + H_2 \). The backward scattering term \( H_{im} \) becomes a very simple form. In order to study low energy behavior of the system where renormalized backward scattering potential \( V^{R}_{2k_F} \) goes to infinity in low energy limit, we rewrite the backward scattering term as the following form

\[ H_{im} = \sum_{\sigma} h v_F \delta[\rho_{1,\sigma}(0) - \rho_{2,\sigma}(0)] \] (6)

where \( \delta = \arctan(V_{2k_F}/(hv_F)) \) is a phase shift induced by the backward scattering potential \( V_{2k_F} \). It is reduced to the \( H_{im} \) in (5) as \( V_{2k_F} \to 0 \). Taking this replacement, we can study the property of the system for any value of \( V_{2k_F} \). The Hilbert space of the fields \( \psi_{R(L),\sigma}(x) \) is different from that of the fields \( \psi_{1(2),\sigma}(x) \) in which the backward scattering term becomes the usual potential scattering in quantum mechanics. However, the transformation (4) is valid for any \( V_{2k_F} \), we can take the phase shift \( \delta \) as a renormalized quantity varying from zero to \( \pm \pi/2 \). This replacement can be justified by the following facts: a). It is usually used in treatment of Kondo problem and is proved to be correct. b). In the interaction-free case, using the Bethe Ansatz it can be shown that the impurity scattering potential dependence of ground-state energy is in the form of phase shift \( \delta \). c). In the phase shift description, at the strong coupling critical points \( \delta^c = \pm \pi/2 \) (corresponding to infinity backward scattering potential) we can easily calculate the Green function and density of state of electrons, and show (see below) that they are completely consistent with previous calculations [12,21]. The bosonic representation of the fermion fields \( \psi_{1(2),\sigma} \) can be written as \( \psi_{1(2),\sigma}(x) = (D_{2\pi hv_F})^{1/2} \exp\{ -i \Phi_{1(2),\sigma}(x) \} \), where \( \rho_{1(2),\sigma}(x) = \psi_{1(2),\sigma}^\dagger(x)\psi_{1(2),\sigma}(x) \) are the density operators, and are related to the boson field \( \Phi_{1(2),\sigma}(x) \) through \( \partial_x \Phi_{1(2),\sigma}(x) = 2\pi \rho_{1(2),\sigma}(x) \).

Performing the unitary transformation

\[ U = \exp \left\{ i \sum_{\sigma} \frac{\delta}{2\pi} [\Phi_{1,\sigma}(0) - \Phi_{2,\sigma}(0)] \right\} \] (7)
we can have the relation

\[ U^\dagger(H_1 + H_2 + H_{im})U = H_1 + U^\dagger H_2 U \]  

(8)

where the unitary transformation of the Hamiltonian \( H_2 \) can be written as

\[ \tilde{H}_2 = U^\dagger H_2 U \]

\[ = -\frac{1}{4} \sum_\sigma \int dx \{ V_1 [e^{-i\delta \text{sgn}(x)} \psi_{1\sigma}^\dagger(x) \psi_{2\sigma}(x) + \text{h.c.}] \]

\[ + V_2 [e^{-i\delta \text{sgn}(x)} \psi_{1\sigma}^\dagger(x) \psi_{2\sigma}(x) + \text{h.c.}] \]

\[ + V_2 [e^{-i\delta \text{sgn}(x)} \psi_{1\sigma}^\dagger(-x) \psi_{2\sigma}(-x) + \text{h.c.}] \]

\[ + V_2 [e^{-i\delta \text{sgn}(x)} \psi_{1\sigma}^\dagger(-x) \psi_{2\sigma}(-x) + \text{h.c.}] \]

Taking the gauge transformations

\[ \psi_{1\sigma}(x) = \bar{\psi}_{1\sigma}(x)e^{i\theta_1}, \quad \psi_{2\sigma}(x) = \bar{\psi}_{2\sigma}(x)e^{i\theta_2}, \quad \theta_1 - \theta_2 = \pm \delta \]  

(10)

which makes \( \tilde{H}_2 \) be more compact, and leaves \( H_1 \) intact, the Hamiltonian \( \tilde{H}_2 = \tilde{H}_2 + \tilde{H}_2' \) can be rewritten as

\[ \tilde{H}_2 = -\frac{V_1 \cos(2\delta)}{4} \sum_\sigma \int dx [\bar{\psi}_{1\sigma}^\dagger(x) \bar{\psi}_{2\sigma}(x) + \text{h.c.}] [\bar{\psi}_{1\sigma}^\dagger(-x) \bar{\psi}_{2\sigma}(-x) + \text{h.c.}] \]

\[ -\frac{V_2 \cos(2\delta)}{4} \sum_\sigma \int dx [\bar{\psi}_{1\sigma}^\dagger(x) \bar{\psi}_{2\sigma}(x) + \text{h.c.}] [\bar{\psi}_{1\sigma}^\dagger(-x) \bar{\psi}_{2\sigma}(-x) + \text{h.c.}] \]  

\[ \tilde{H}_2' = i \frac{V_1 \sin(2\delta)}{2} \sum_\sigma \int_0^\infty dx [\bar{\psi}_{1\sigma}^\dagger(x) \bar{\psi}_{2\sigma}(x) - \text{h.c.}] [\bar{\psi}_{1\sigma}^\dagger(-x) \bar{\psi}_{2\sigma}(-x) + \text{h.c.}] \]

\[ + i \frac{V_2 \sin(2\delta)}{2} \sum_\sigma \int_0^\infty dx [\bar{\psi}_{1\sigma}^\dagger(x) \bar{\psi}_{2\sigma}(x) - \text{h.c.}] [\bar{\psi}_{1\sigma}^\dagger(-x) \bar{\psi}_{2\sigma}(-x) + \text{h.c.}] \]

To further simplify the Hamiltonian \( \tilde{H}_2 \), we can re-define the left- and right-moving electron fields

\[ \bar{\psi}_{R\sigma}(x) = \frac{1}{\sqrt{2}} [\psi_{1\sigma}(x) + \psi_{2\sigma}(x)], \quad \bar{\psi}_{L\sigma}(-x) = \frac{1}{\sqrt{2}} [\psi_{1\sigma}(x) - \psi_{2\sigma}(x)] \]  

(12)

The Hamiltonian \( \tilde{H}_2' \) becomes

\[ \tilde{H}_2' = \pm i \frac{V_1 \sin(2\delta)}{2} \sum_\sigma \int_0^\infty dx [\bar{\psi}_{L\sigma}^\dagger(-x) \bar{\psi}_{R\sigma}(x) - \text{h.c.}] [\bar{\rho}_{R\sigma}(-x) - \bar{\rho}_{L\sigma}(x)] \]

\[ \pm i \frac{V_2 \sin(2\delta)}{2} \sum_\sigma \int_0^\infty dx [\bar{\psi}_{L\sigma}^\dagger(-x) \bar{\psi}_{R\sigma}(x) - \text{h.c.}] [\bar{\rho}_{R\sigma}(-x) - \bar{\rho}_{L\sigma}(x)] \]
where $\bar{\rho}_{R(L)}(x) = \bar{\psi}^\dagger_{R(L)}(x)\bar{\psi}_{R(L)}(x)$ are the density operators. The Hamiltonian $\tilde{H}'_2$ has a conformal dimension $\Delta > 1$ because the field $\bar{\rho}_{R\sigma}(x) - \bar{\rho}_{L\sigma}(-x)$ has the conformal dimension one and the fields $\bar{\psi}^\dagger_{L\sigma}(-x)\bar{\psi}_{R\sigma}(x)$ and $\bar{\psi}^\dagger_{R\sigma}(x)\bar{\psi}_{L\sigma}(-x)$ have the conformal dimension $\Delta' > 1$ which can be seen from Eq. (24), we can neglect it as a first order approximation. It is zero at the strong coupling critical points $\delta^c = \pm\pi/2$, $\tilde{H}'_2 \equiv 0$. The total Hamiltonian $\bar{H} = H_1 + \tilde{H}_2$ can be simplified as

$$\bar{H} = -i\hbar v_F \sum_\sigma \int dx [\bar{\psi}^\dagger_{R\sigma}(x)\partial_x\bar{\psi}_{R\sigma}(x) - \bar{\psi}^\dagger_{L\sigma}(x)\partial_x\bar{\psi}_{L\sigma}(x)]$$

$$+ \frac{V_1}{2} \sum_\sigma \int dx [\alpha \bar{\rho}_{R\sigma}(x)\bar{\rho}_{R\sigma}(-x) + \alpha \bar{\rho}_{L\sigma}(x)\bar{\rho}_{L\sigma}(-x) + 2\beta \bar{\rho}_{R\sigma}(x)\bar{\rho}_{L\sigma}(x)]$$

$$+ \frac{V_2}{2} \sum_\sigma \int dx [\alpha \bar{\rho}_{R\sigma}(-x)\bar{\rho}_{R\sigma}(x) + \alpha \bar{\rho}_{L\sigma}(-x)\bar{\rho}_{L\sigma}(x) + 2\beta \bar{\rho}_{R\sigma}(x)\bar{\rho}_{L\sigma}(x)]$$

where $\alpha = \frac{1}{2}[1 - \cos(2\delta)]$, and $\beta = \frac{1}{2}[1 + \cos(2\delta)]$. For $\delta = 0$, without the impurity scattering, we have $\alpha = 0$ and $\beta = 1$, the Hamiltonian (13) becomes the original one (1). In terms of these new electron fields $\bar{\psi}_{R(L)\sigma}(x)$, the interaction Hamiltonian $\bar{H}'_i$ (last two terms) becomes a very simple form, and the right- and left-moving electrons are completely separated at the critical points $\delta^c = \pm\pi/2$ induced by the backward scattering potential. However, for a general phase shift $\delta$, the total Hamiltonian (13) becomes little complex and non-local. The non-locality of the interaction terms is the most prominent character of the backward scattering of the conduction electrons on the impurity, which strongly influences the low energy behavior of the system.

### III. A MAGNETIC IMPURITY SCATTERING

Now we consider a magnetic impurity scattering, the Kondo interaction term is

$$H_K = \sum_i J_0^i [s_{R\sigma}^i(0) + s_{L\sigma}^i(0)] \cdot S + \sum_i J_{2kF}^i [s_{RL\sigma}^i(0) + s_{LR\sigma}^i(0)] \cdot S^i$$

(14)

where $S$ is the impurity spin operator ($S = 1/2$), $s_{R(L)\alpha}^i(0) = \frac{1}{2}\psi^\dagger_{R(L)\alpha}(0)\sigma_{\alpha\beta}^i\psi_{R(L)\beta}(0)$, $s_{RL\sigma}^i(0) = \frac{1}{2}\psi^\dagger_{Ro\sigma}(0)\sigma_{\alpha\beta}^i\psi_{L\beta}(0)$, and $s_{LR\sigma}^i(0) = \frac{1}{2}\psi^\dagger_{Lo\sigma}(0)\sigma_{\alpha\beta}^i\psi_{R\beta}(0)$. In terms of the fields $\psi_{1(2)\sigma}(x)$, it can be written as
\[ H_K = \sum_i J_0^i [s_1^i(0) + s_2^i(0)] \cdot S^i + \sum_i J_{2kF}^i [s_1^i(0) - s_2^i(0)] \cdot S^i \]  

(15)

where \( s_1^i(0) = \frac{1}{2} \phi^{(2)\alpha}_i(0) \sigma_{\alpha\beta}^i \phi^{(2)\beta}_i(0) \). Just as for the non-magnetic impurity case, we replacing the interaction potentials \( J_0^i \) and \( J_{2kF}^i \) by the phase shifts \( \bar{\delta} \) and and \( \delta \), respectively, where \( \bar{\delta} = \arctan[J_0^\delta/(4hv_s)] \), and \( \delta = \arctan[J_{2kF}^\delta/(4hv_F)] \). Performing the unitary transformation

\[ U' = \exp\left\{ \frac{2g_s \delta}{\pi} \Phi_s(0) S^z + \frac{2\delta}{\pi} \Phi_{-s}(0) S^z \right\} \]  

(16)

where \( \Phi_{\pm s}(0) = \frac{1}{2} \left[ \Phi_{1\uparrow}(0) - \Phi_{1\downarrow}(0) \right] \pm \left[ \Phi_{2\uparrow}(0) - \Phi_{2\downarrow}(0) \right] \), and taking the gauge transformations

\[ \psi_{1\sigma}(x) = \tilde{\psi}_{1\sigma}(x)e^{i\theta_1}, \quad \psi_{2\sigma}(x) = \tilde{\psi}_{2\sigma}(x)e^{i\theta_2}, \quad \theta_1 - \theta_2 = 2\delta S^z \]  

(17)

where \( \sigma = +1 \) for spin-up \( \uparrow \), and \( \sigma = -1 \) for spin-down \( \downarrow \), we have the relations \( U'^\dagger(U + U') = H_1 + H_2 + H^{''}_2 + H_K \), where the Hamiltonians \( H_1 \) and \( H_2 \) are the same as that for the non-magnetic impurity case (3) and (11), and

\[ H_K = \frac{J_1 D}{2\pi h_F} \left\{ e^{-i(\theta_1 + \delta S^z)} \Phi_{s\uparrow}(0) e^{-i(\theta_2 + \delta S^z)} \Phi_{-s\uparrow}(0) S^+ + h.c. \right\} \]

\[ + \frac{J_2 D}{2\pi h_F} \left\{ e^{-i(\theta_1 + \delta S^z)} \Phi_{s\downarrow}(0) e^{i(\theta_2 - \delta S^z)} \Phi_{-s\downarrow}(0) S^+ + h.c. \right\} \]

(18)

\[ H^{''}_2 = \pm i \frac{V_1 \sin(2\delta)}{2} S^z \sum_{\sigma} \int_0^\infty dx [\tilde{\psi}_{L\sigma}^\dagger(x) \tilde{\psi}_{R\sigma}(x) - h.c.] [\tilde{\rho}_{R\sigma}(x) - \tilde{\rho}_{L\sigma}(x)] \]

\[ \pm i \frac{V_2 \sin(2\delta)}{2} S^z \sum_{\sigma} \int_0^\infty dx [\tilde{\psi}_{L\sigma}^\dagger(x) \tilde{\psi}_{R\sigma}(x) - h.c.] [\tilde{\rho}_{R-\sigma}(x) - \tilde{\rho}_{L-\sigma}(x)] \]

where \( J_1 + J_2 = J_0^\delta = J_0^\delta \), and \( J_1 - J_2 = J_{2kF}^\delta = J_{2kF}^\delta \). The Hamiltonian \( H^{''}_2 \), similar to \( H_2 \), has a conformal dimension \( \Delta' > 1 \), it only contributes higher order correction in the calculation correlation functions, it can be neglected as first order approximation. In the following discussion about the magnetic impurity scattering, we only consider the regions around the fixed points \( \delta = 0 \) and \( \delta^c = \pm \pi/2 \), at these fixed points the Hamiltonian \( H^{''}_2 \) is zero, it is reasonable to neglect the Hamiltonian \( H^{''}_2 \) as first order approximation. Therefore, except the Hamiltonian \( H_K \) for the magnetic impurity scattering, both for the magnetic and non-magnetic impurity scattering, there exists the same total bulk Hamiltonian \( H_1 + H_2 \).
It can be easily understood because for the magnetic impurity scattering the $J_0^z$- and $J_{2k_F}^z$-term in fact are usual forward and backward scattering potential terms, respectively. The low energy behavior of the system is completely determined by the total bulk Hamiltonian $H_1 + \tilde{H}_2$. The effect of the impurity scattering on the electrons is reflected on the change of the interactions among the electrons.

IV. CALCULATION OF ELECTRON GREEN FUNCTION

We first use the Hamiltonian $\tilde{H}$ (13) to calculate the Green function of the electron fields $\tilde{\psi}_{iR(L)\sigma}(x, \tau)$. The action of the system can be written as

\[
S = \sum_\sigma \int_0^{1/(k_BT)} d\tau \int dx \{ \bar{\psi}^\dagger_{R\sigma}(x, \tau)(\partial_\tau - i\partial_x)\psi_{R\sigma}(x, \tau) \\
+ \bar{\psi}^\dagger_{L\sigma}(x, \tau)(\partial_\tau + i\partial_x)\psi_{L\sigma}(x, \tau) \} \\
- i\sum_\sigma \int_0^{1/(k_BT)} d\tau \int dx \{ \phi_{R\sigma}(x, \tau)[\bar{\rho}_{R\sigma}(x, \tau) - \bar{\psi}^\dagger_{R\sigma}(x, \tau)\psi_{R\sigma}(x, \tau)] \\
+ \phi_{L\sigma}(x, \tau)[\bar{\rho}_{L\sigma}(x, \tau) - \bar{\psi}^\dagger_{L\sigma}(x, \tau)\psi_{L\sigma}(x, \tau)] \} \\
+ \frac{V_1}{2} \sum_\sigma \int_0^{1/(k_BT)} d\tau \int dx \{ \alpha\bar{\rho}_{R\sigma}(x, \tau)\bar{\rho}_{R\sigma}(-x, \tau) \\
+ \alpha\bar{\rho}_{L\sigma}(x, \tau)\bar{\rho}_{L\sigma}(-x, \tau) + 2\beta\bar{\rho}_{R\sigma}(x, \tau)\bar{\rho}_{L\sigma}(x, \tau) \} \\
+ \frac{V_2}{2} \sum_\sigma \int_0^{1/(k_BT)} d\tau \int dx \{ \alpha\bar{\rho}_{R\sigma}(x, \tau)\bar{\rho}_{R\sigma}(-x, \tau) \\
+ \alpha\bar{\rho}_{L\sigma}(x, \tau)\bar{\rho}_{L\sigma}(-x, \tau) + 2\beta\bar{\rho}_{R\sigma}(x, \tau)\bar{\rho}_{L\sigma}(x, \tau) \} \tag{19}
\]

where $T$ is temperature, and the auxiliary fields $\phi_{R(L)\sigma}(x, \tau)$ are the Lagrangians that introduce the constraint conditions $\bar{\rho}_{R(L)\sigma}(x, \tau) = \bar{\psi}^\dagger_{R(L)\sigma}(x, \tau)\psi_{R(L)\sigma}(x, \tau)$. We have chosen $\hbar = v_F = 1$. The Green function of the electrons $\bar{\psi}_{R(L)\sigma}(x, \tau)$ can be written as

\[
G_{R(L)\sigma}(x, \tau; x', \tau') = \frac{1}{\Omega} \int \prod D\psi \prod D\bar{\psi}^\dagger \prod D\rho \prod D\phi \psi_{R(L)\sigma}(x, \tau)\bar{\psi}_{R(L)\sigma}(x', \tau') e^{-S} \\
= \frac{1}{\Omega} \int \prod D\psi \prod D\bar{\psi}^\dagger \prod D\rho \prod D\phi G_{R(L)\sigma}(x, \tau; x', \tau', [\phi]) e^{-S} \\
= \frac{1}{\Omega} \int \prod D\psi \prod D\bar{\psi}^\dagger \prod D\rho \prod D\phi G_{R(L)\sigma}(x, \tau; x', \tau', [\rho]) e^{-S} \tag{20}
\]

where $\Omega = \int \prod D\psi \prod D\bar{\psi}^\dagger \prod D\rho \prod D\phi e^{-S}$ is the partition functional of the system, $\prod DX = \prod_\sigma DX_{R\sigma}(x, \tau)DX_{L\sigma}(x, \tau)$, where $X = (\bar{\psi}^\dagger, \bar{\psi}, \bar{\rho}, \phi)$. The Green function
\( G_{R(L)}(x, \tau; x', \tau', [\rho]) \) can be obtained by using the boson representation of the electron fields \( \psi_{R(L)}(x, \tau) \). The Green functions \( G_{R(L)}(x, \tau; x', \tau', [\phi]) \) satisfy the equation

\[
[\partial_\tau + i \partial_x + i \phi_{R(L)}(x, \tau)] G_{R(L)}(x, \tau; x', \tau', [\phi]) = -\delta(x - x')\delta(\tau - \tau')
\]  

(21)

Because this is the first order linear differential equation, we can take the following Factorization Ansatz \([27]\)

\[
G_{R(L)}(x, \tau; x', \tau', [\phi]) = G^{0}_{R(L)}(x - x', \tau - \tau') \cdot \exp\{f_{R(L)}(x, \tau, [\phi]) - f^{0}_{R(L)}(x', \tau', [\phi])\}
\]  

(22)

where \([\partial_\tau + i \partial_x]G^{0}_{R(L)}(x, \tau) = -\delta(x)\delta(\tau)\), and the fields \(f_{R(L)}(x, \tau, [\phi])\) satisfy the equation

\[
[\partial_\tau + i \partial_x]f_{R(L)}(x, \tau, [\phi]) = -i \phi_{R(L)}(x, \tau)
\]  

(23)

which can be easily solved \([28]\) \(f_{R(L)}(x, \tau, [\phi]) = k_B T \sum_n \int \frac{dp}{2\pi} f_{R(L)}(p, \omega_n, [\phi]) e^{ipx - \omega_n \tau}\), where \(f_{R(L)}(p, \omega_n, [\phi]) = i \phi_{R(L)}(p, \omega_n) / (i \omega_n + p)\). Therefore, in order to calculate the Green function \(G_{R(L)}(x, \tau; x', \tau')\), we need to know the effective action \(S_{eff}[\bar{\rho}, \phi]\). After introducing the auxiliary fields \(\phi_{R(L)}(x, \tau)\), there is only the quadratic form of the electron fields \(\psi_{R(L)}(x, \tau)\) in Eq. (19), we can integrate out them and obtain the potential function \(W(x, \tau) = Tr \ln(\partial_\tau - i \partial_x + i \phi_{Ro}) + Tr \ln(\partial_\tau + i \partial_x + i \phi_{Lo})\), which can be calculated by using the Green functions \([22]\) \(W(x, \tau) = \frac{i}{2} [\phi_{R_o}(x, \tau)] G_{Ro}(x, \tau; x' \rightarrow x, \tau' \rightarrow \tau) + \phi_{Lo}(x, \tau) G_{Lo}(x, \tau; x' \rightarrow x, \tau' \rightarrow \tau)\). After integrating out the fields \(\psi_{R(L)}(x, \tau)\), we can obtain the effective action

\[
S_{eff}[\bar{\rho}, \phi] = k_B T \sum_{\sigma} \sum_{n} \int \frac{dp}{2\pi} [A_R |\phi_{Ro}(p, \omega_n)|^2 + A_L |\phi_{Lo}(p, \omega_n)|^2] \\
- i \sum_{\sigma} \int_0^{1/(k_B T)} d\tau \int dx \{\phi_{Ro}(x, \tau) \bar{\rho}_{Ro}(x, \tau) + \phi_{Lo}(x, \tau) \bar{\rho}_{Lo}(x, \tau)\} \\
+ \frac{V_1}{2} \sum_{\sigma} \int_0^{1/(k_B T)} d\tau \int dx \{\alpha \bar{\rho}_{Ro}(x, \tau) \bar{\rho}_{Ro}(-x, \tau) \\
+ \alpha \bar{\rho}_{Lo}(x, \tau) \bar{\rho}_{Lo}(-x, \tau) + 2\beta \bar{\rho}_{Ro}(x, \tau) \bar{\rho}_{Lo}(x, \tau)\} \\
+ \frac{V_2}{2} \sum_{\sigma} \int_0^{1/(k_B T)} d\tau \int dx \{\alpha \bar{\rho}_{Ro}(x, \tau) \bar{\rho}_{Ro}(-x, \tau) \\
+ \alpha \bar{\rho}_{Lo}(x, \tau) \bar{\rho}_{Lo}(-x, \tau) + 2\beta \bar{\rho}_{Ro}(x, \tau) \bar{\rho}_{Lo}(x, \tau)\}
\]  

(24)
where \( A_{R(L)} = \mp \frac{1}{4\pi e \ln \omega + p} \). Integrating out the auxiliary fields \( \phi_{R(L)\sigma}(x, \tau) \), we can obtain the spin and charge collective excitation spectrums

\[
\epsilon_c = \pm [1 - (\alpha \pm \beta)^2 \gamma_c^2]^{1/2} p
\]

\[
\epsilon_s = \pm [1 - (\alpha \pm \beta)^2 \gamma_s^2]^{1/2} p
\]  (25)

It is noting that the charge and spin spectrums are influenced by the impurity scattering, which induces the exponents of the electron Green function and other correlation functions depending on the phase shift \( \delta \). After integrating out the fields \( \bar{\rho}_{R(L)\sigma}(x, \tau) \) and \( \phi_{R(L)\sigma}(x, \tau) \) in Eq.(20), and taking the Wick rotation \( \tau \to it, \ t' \to it' \), we can obtain the electron Green function expression \( \Delta t > 0 \)

\[
G_{R(L)\sigma}(x, t; x', t') = e^{i k_F \Delta x - Q_{R(L)}(x, t; x', t')}
\]

\[
Q_{R(L)}(x, t; x', t') = \frac{1}{4} \sum_j \ln[(\Delta x \mp \alpha_j \Delta t \pm i\eta)(\Delta x \mp \alpha_j - \Delta t \pm i\eta)]
\]

\[
+ \frac{1}{8} \sum_j \frac{1}{(\alpha_j^+ - 1)} \ln[(\Delta x \mp \alpha_j^+ \Delta t \mp i\eta)(\Delta x \mp \alpha_j^+ - \Delta t \pm i\eta)]
\]

\[
+ \frac{1}{8} \sum_j \frac{1}{(\alpha_j^- - 1)} \ln[(\Delta x \mp \alpha_j^- \Delta t \mp i\eta)(\Delta x \mp \alpha_j^- - \Delta t \pm i\eta)]
\]

\[
+ \frac{\alpha}{16} \sum_j \frac{\gamma_j}{\alpha_j^+} \ln \left[ \frac{(x + x' + \alpha_j^+ \Delta t - i\eta)^2(x + x' - \alpha_j^+ \Delta t + i\eta)^2}{(2x + i\eta)(2x - i\eta)(2x' + i\eta)(2x' - i\eta)} \right]
\]

\[
+ \frac{\alpha}{16} \sum_j \frac{\gamma_j}{\alpha_j^-} \ln \left[ \frac{(x + x' + \alpha_j^- \Delta t - i\eta)^2(x + x' - \alpha_j^- \Delta t + i\eta)^2}{(2x + i\eta)(2x - i\eta)(2x' + i\eta)(2x' - i\eta)} \right]
\]

\[
+ \frac{\alpha^2}{32} \sum_j \frac{\gamma_j^2}{\alpha_j^+} \ln \left[ \frac{(x + x' + \alpha_j^+ \Delta t - i\eta)^2(x + x' - \alpha_j^+ \Delta t + i\eta)^2}{(2x + i\eta)(2x - i\eta)(2x' + i\eta)(2x' - i\eta)} \right]
\]

\[
+ \frac{\alpha^2}{32} \sum_j \frac{\gamma_j^2}{\alpha_j^-} \ln \left[ \frac{(x + x' + \alpha_j^- \Delta t - i\eta)^2(x + x' - \alpha_j^- \Delta t + i\eta)^2}{(2x + i\eta)(2x - i\eta)(2x' + i\eta)(2x' - i\eta)} \right]
\]  (26)

where, \( \alpha_{j\pm}^2 = 1 - (\alpha \pm \beta)^2 \gamma_j^2, j = c, s \), \( \Delta x = x - x', \Delta t = t - t', \eta \) is the ultraviolet cut-off factor which is proportional to \( D^{-1} \). It is easily to demonstrate that at the strong coupling critical points \( \delta^c = \pm \pi/2 \), \( G_{R(L)\sigma}(0, t; 0, 0) \sim t^{-(1/g_c+1/g_s)/2} \), and at \( \delta = 0 \), \( G_{R(L)\sigma}(0, t; 0, 0) \sim t^{-(g_c+1/g_c+g_s+1/g_s)/4} \). The usual duality relation of the correlation exponents near the impurity site \( x = 0 \) between the ultraviolet \( (\delta = 0) \) and the infrared fixed points \( (\delta^c = \pm \pi/2) \) is also valid even including the spin degrees of the electrons \[29\]. However, it is more important
that the correlation exponents are depending on the phase shift $\delta$, which is consistent with that both the charge and spin collective excitation spectrums and the interaction among electrons are altered by the impurity scattering. From Eq. (24) we can obtain the density of state of the electrons which depends on the distance away from the impurity site. At the strong coupling critical points $\delta^c = \pm \pi/2$, we can obtain the relation

$$D_{R(L)}^c(x, \omega) \sim \begin{cases} \omega^{(1/g_c+1/g_s)/2-1}, & x \to 0 \\ \omega^{(g_c+1/g_c+g_s+1/g_s)/4-1}, & x \to \infty \end{cases}$$

(27)

which is consistent with previous calculations [12,21]. The impurity backward scattering suppresses the density of state of electrons near the impurity site $x = 0$, but has little influence on the electron density of state far away from the impurity.

We can also use the Hamiltonians $H_1$ (5) and $\tilde{H}_2$ (11) to calculate the Green’s function of the fermion fields $\tilde{\psi}_{1(2)} \sigma(x)$ by using the same method as above. The action of the system can be written as

$$S' = \sum_{\sigma} \int_0^{1/(k_BT)} d\tau \int dx \{ \tilde{\psi}_{1(2)} \sigma(x, \tau) (\partial_\tau - i \partial_x) \tilde{\psi}_{1(2)} \sigma(x, \tau) \\
+ i \phi_1 \sigma(x, \tau) [\tilde{\rho}_{1(2)} \sigma(x, \tau) - \tilde{\psi}_{1(2)} \sigma(x, \tau) \tilde{\psi}_{1(2)} \sigma(x, \tau)] \\
- i \phi_2 \sigma(x, \tau) [\tilde{\rho}_{1(2)} \sigma(x, \tau) - \tilde{\psi}_{1(2)} \sigma(x, \tau) \tilde{\psi}_{1(2)} \sigma(x, \tau)] \\
- i \lambda_1 \sigma(x, \tau) [\Gamma_{1(2)} \sigma(x, \tau) - \tilde{\psi}_{1(2)} \sigma(x, \tau) \tilde{\psi}_{1(2)} \sigma(x, \tau)] \\
- i \lambda_2 \sigma(x, \tau) [\Gamma_{1(2)} \sigma(x, \tau) - \tilde{\psi}_{1(2)} \sigma(x, \tau) \tilde{\psi}_{1(2)} \sigma(x, \tau)] \\
+ \frac{V_1}{4} [\tilde{\rho}_{1(2)} \sigma(x, \tau) + \tilde{\rho}_{2(2)} \sigma(x, \tau)][\tilde{\rho}_{1(2)} \sigma(-x, \tau) + \tilde{\rho}_{2(2)} \sigma(-x, \tau)] \\
+ \frac{V_2}{4} [\tilde{\rho}_{1(2)} \sigma(x, \tau) + \tilde{\rho}_{2(2)} \sigma(x, \tau)][\tilde{\rho}_{1(2)} \sigma(-x, \tau) + \tilde{\rho}_{2(2)} \sigma(-x, \tau)] \\
- \frac{V_1 \cos(2\delta)}{4} [\Gamma_{1(2)} \sigma(x, \tau) + \Gamma_{2(2)} \sigma(x, \tau)][\Gamma_{1(2)} \sigma(-x, \tau) + \Gamma_{2(2)} (-x, \tau)] \\
- \frac{V_2 \cos(2\delta)}{4} [\Gamma_{1(2)} \sigma(x, \tau) + \Gamma_{2(2)} \sigma(x, \tau)][\Gamma_{1(2)} \sigma(-x, \tau) + \Gamma_{2(2)} (-x, \tau)] \}$$

(28)

where the auxiliary fields $\lambda_{1(2)} \sigma(x, \tau)$ introduce the constraint conditions $\Gamma_{1(2)} \sigma(x, \tau) = \tilde{\psi}^\dagger_{1(2)} \sigma(x, \tau) \tilde{\psi}_{2(1)} \sigma(x, \tau)$. The Green functions of the fermions $\tilde{\psi}_{R(L)} \sigma(x, \tau)$ can be written as
\begin{equation}
G_{11(22)\sigma}(x, \tau; x', \tau') = \frac{1}{\Omega} \int \prod D\bar{\psi} \prod D\psi^\dagger \prod D\bar{\phi} \prod D\phi \bar{\psi}_{1(2)\sigma}(x', \tau') \psi_{1(2)\sigma}(x, \tau) e^{-S'} = \frac{1}{\Omega} \int \prod D\bar{\psi} \prod D\psi^\dagger \prod D\bar{\phi} \prod D\phi G_{11(22)\sigma}(x, \tau; x', \tau', [\phi, \lambda]) e^{-S'}
\end{equation}

where $G_{11(22)\sigma}(x, \tau; x', \tau', [\phi, \lambda])$ satisfy the linear differential equation

\begin{equation}
(D + i\phi_\sigma, i\lambda_\sigma) \begin{pmatrix} G_{11}, G_{12} \\ i\lambda_\sigma, D + i\phi_\sigma \end{pmatrix} = -\begin{pmatrix} \delta(x-x')\delta(\tau-\tau'), 0 \\ 0, \delta(x-x')\delta(\tau-\tau') \end{pmatrix}
\end{equation}

where $D = \partial_\tau - i\partial_x$, $G_{ij} = G_{ij}(x, \tau; x', \tau', [\phi, \lambda])$, $i, j = 1, 2$, and we have taken $\phi_{1\sigma}(x, \tau) = \phi_{2\sigma}(x, \tau)$ and $\lambda_{1\sigma}(x, \tau) = \lambda_{2\sigma}(x, \tau)$, because in the action $S'$ there only appears the terms $\bar{\rho}_{1\sigma} + \bar{\rho}_{2\sigma}$ and $\Gamma_{1\sigma} + \Gamma_{2\sigma}$, after integrating out the fields $\bar{\rho}_{1(2)\sigma}(x, \tau)$ and $\Gamma_{1(2)\sigma}(x, \tau)$ we have the relations $\phi_{1\sigma}(x, \tau) = \phi_{2\sigma}(x, \tau)$ and $\lambda_{1\sigma}(x, \tau) = \lambda_{2\sigma}(x, \tau)$. Using the factorization Ansatz

\begin{equation}
\begin{cases}
G_{11(22)} = \frac{1}{2} G^0(x, \tau; x', \tau') [e^{\tilde{f}_\sigma(x, \tau) - \tilde{f}_\sigma(x', \tau')} + e^{\tilde{f}_\sigma(x', \tau') - \tilde{f}_\sigma(x, \tau)}] e^{f_\sigma(x, \tau) - f_\sigma(x', \tau')}
G_{12(21)} = \frac{1}{2} G^0(x, \tau; x', \tau') [e^{\tilde{f}_\sigma(x, \tau) - \tilde{f}_\sigma(x', \tau')} - e^{\tilde{f}_\sigma(x', \tau') - \tilde{f}_\sigma(x, \tau)}] e^{f_\sigma(x, \tau) - f_\sigma(x', \tau')}
\end{cases}
\end{equation}

where $D G^0(x, \tau; x', \tau') = -\delta(x-x')\delta(\tau-\tau')$. If the fields $f_\sigma(x, \tau)$ and $\tilde{f}_\sigma(x, \tau)$ satisfy the equations

\begin{equation}
\begin{cases}
D f_\sigma(x, \tau) = -i\phi_\sigma(x, \tau)
D \tilde{f}_\sigma(x, \tau) = -i\lambda_\sigma(x, \tau)
\end{cases}
\end{equation}

we can easily prove that the expression (31) is the exact solution of the Eq.(30). After integrating out the fields $\psi_{1(2)\sigma}(x, \tau)$, $\bar{\rho}_{1(2)\sigma}(x, \tau)$ and $\Gamma_{1(2)\sigma}(x, \tau)$, we can obtain the effective action

\begin{equation}
S_{\text{eff}}[\phi, \lambda] = k_B T \sum_n \int \frac{dp}{2\pi} \left\{ A(p, \omega_n) [|\phi_c(p, \omega_n)|^2 + |\phi_s(p, \omega_n)|^2] + A(p, \omega_n) [|\lambda_c(p, \omega_n)|^2 + |\lambda_s(p, \omega_n)|^2]
+ \frac{1}{V_1 + V_2} \phi_c(p, -\omega_n) \phi_c(p, \omega_n) + \frac{1}{V_1 - V_2} \phi_s(p, -\omega_n) \phi_s(p, \omega_n)
- \frac{1}{(V_1 + V_2) \cos(2\delta)} \lambda_c(p, -\omega_n) \lambda_c(p, \omega_n) - \frac{1}{(V_1 - V_2) \cos(2\delta)} \lambda_s(p, -\omega_n) \lambda_s(p, \omega_n) \right\}
\end{equation}
where \( A(p, \omega_n) = \frac{1}{2\pi p} p \cdot wn \), \( \phi_{c(s)}(p, \omega_n) = \frac{\sqrt{2}}{2} [\phi_1(p, \omega_n) \pm \phi_1(p, \omega_n)] \), and \( \lambda_{c(s)}(p, \omega_n) = \frac{\sqrt{2}}{2} [\lambda_1(p, \omega_n) \pm \lambda_1(p, \omega_n)] \). Using the effective action \( S_{\text{eff}}[\phi, \lambda] \), we can obtain the relations after taking the Wick rotation (\( \Delta t > 0 \))

\[
< e^{f_\sigma(x,t)-f_\delta(x',t')} > = \left[ \frac{(\Delta x - \Delta t + i\eta)^2}{(\Delta x - \alpha_\epsilon \Delta t + i\eta)(\Delta x - \alpha_\delta \Delta t + i\eta)} \right]^{1/4} \cdot \prod_j \left[ (\Delta x + \alpha_j \Delta t - i\eta)(\Delta x - \alpha_j \Delta t + i\eta) \right]^{-\mu_j/4}
\]

\[
< e^{\tilde{f}_\sigma(x,t)-\tilde{f}_\delta(x',t')} > = \left[ \frac{(\Delta x - \Delta t + i\eta)^2}{(\Delta x - \bar{\alpha}_\epsilon \Delta t + i\eta)(\Delta x - \bar{\alpha}_\delta \Delta t + i\eta)} \right]^{1/4} \cdot \prod_j \left[ (\Delta x + \bar{\alpha}_j \Delta t - i\eta)(\Delta x - \bar{\alpha}_j \Delta t + i\eta) \right]^{-\bar{\mu}_j/4}
\]

\[
\cdot \prod_j \left[ \frac{(x + x' + \alpha_j \Delta t - i\eta)^2(x + x' - \alpha_j \Delta t + i\eta)^2}{(2x + i\eta)(2x - i\eta)(2x' + i\eta)(2x' - i\eta)} \right]^{-\nu_j/8}
\]

where \( \alpha_j^2 = 1 - \gamma_j^2 \), \( \bar{\alpha}_j^2 = 1 - \cos^2(2\delta) \gamma_j^2 \), \( \mu_j = \frac{1}{2}(\frac{1}{\alpha_j} - 1) \), \( \bar{\mu}_j = \frac{1}{2}(\frac{1}{\bar{\alpha}_j} - 1) \), \( \nu_j = \frac{\gamma_j}{2\alpha_j} \), and \( \bar{\nu}_j = -\frac{\gamma_j \cos(2\delta)}{2\bar{\alpha}_j} \), where \( j = c, s \). The Green functions of the fermions \( \tilde{\psi}_{1(2)\sigma}(x, t) \) can be written as

\[
G_{11(22)}(x, t, x', t') = G^0(x, t; x', t') < e^{f_\sigma(x,t)-f_\delta(x',t')} > < e^{\tilde{f}_\sigma(x,t)-\tilde{f}_\delta(x',t')} >
\]

In the impurity-free case, \( \delta = 0 \), the Green functions \( G_{11(22)}(0, t; 0, 0) \) have the asymptotic form in the long time limit

\[
G_{11(22)}(0, t; 0, 0) \sim t^{-(g_\epsilon + 1/g_\epsilon)/4-(g_s + 1/g_s)/4}
\]

At the strong coupling critical points \( \delta^c = \pm \pi/2 \), they have the form

\[
G_{11(22)}^c(0, t; 0, 0) \sim t^{-\frac{1}{2\sigma} - \frac{1}{2\sigma}}
\]

It would be pointed out that at \( \delta = 0 \) and the strong coupling critical points \( \delta^c = \pm \pi/2 \), the Green functions \( G_{R(L)}(0, t; 0, 0) \) and \( G_{11(22)}(0, t; 0, 0) \) both have the same asymptotic form in the long time limit which is different from previous mean field approximation calculation.
From Eq. (38), we can obtain the density of state of the fermions $\bar{\psi}_{1(2)\sigma}(x)$ at the strong coupling critical points $\delta^c = \pm \pi/2$

$$D^c_{1(2)}(0, \omega) \sim \omega^{(1/g_c+1/g_s)/2-1}$$

which is consistent with Eq. (27) for the $x \to 0$ case. It is clearly shown in (27) and (38) that the density of state of electrons near the impurity is suppressed by the backward scattering, but the density of state of electrons far away from the impurity remains intact.

V. SCATTERING OF ELECTRONS ON THE IMPURITY SITE $X=0$

We now study the scattering of electrons on the impurity site $x = 0$. There is some controversy on this topics. One usually believes that at zero temperature the electrons are completely reflected on the impurity site, therefore there exist the boundary conditions $\psi_{R\sigma}(x, t) = \pm \psi_{L\sigma}(-x, t)$, because the backward scattering potential is renormalized to infinity as temperature going to zero. However, our exact solution of the Green functions $G_{11}(x, t; x', t')$ and $G_{22}(x, t; x', t')$ in (36) both have the same expressions even at the strong coupling critical points $\delta^c = \pm \pi/2$. Therefore, at zero temperature even though the electrons are completely reflected on the impurity site, it does not mean that the boundary conditions $\psi_{R\sigma}(x, t) = \pm \psi_{L\sigma}(-x, t)$ are correct. In this section, we give a correct boundary condition which heavily depends on the phase shift $\delta$.

The influence of the impurity scattering on the electron fields $\psi_{R(L)\sigma}(x)$ is determined by the unitary transformation $U$, after simple calculation we can obtain the relations

$$U^\dagger \psi_{R\sigma}(x) U = \frac{1}{2} e^{i\theta_1} e^{\frac{i}{2} \text{sgn}(x)} \{ [1 + e^{-i\delta(1+\text{sgn}(x))}] \bar{\psi}_{R\sigma}(x) $$
$$+ [1 - e^{-i\delta(1+\text{sgn}(x))}] \bar{\psi}_{L\sigma}(-x) \}$$

$$U^\dagger \psi_{L\sigma}(x) U = \frac{1}{2} e^{i\theta_1} e^{\frac{i}{2} \text{sgn}(x)} \{ [1 - e^{i\delta(1-\text{sgn}(x))}] \bar{\psi}_{R\sigma}(-x) $$
$$+ [1 + e^{i\delta(1-\text{sgn}(x))}] \bar{\psi}_{L\sigma}(x) \}$$

where for simplicity we have taken the gauge parameters $\theta_{1(2)}$ satisfying $\theta_1 - \theta_2 = \delta$. For
more clearly showing the influence of the impurity scattering on electron fields, we consider
the following two cases. One is for the case of \( x > 0 \), the relations (40) can be rewritten as
\[
U^\dagger \psi_R(x) U = \frac{1}{2} e^{i \theta_1} e^{i \frac{\pi}{4}} [(1 + e^{-i 2 \delta}) \bar{\psi}_R(x) + (1 - e^{-i 2 \delta}) \bar{\psi}_L(-x)]
\]
\[
U^\dagger \psi_L(x) U = e^{i \theta_1} e^{-i \frac{\pi}{4}} \bar{\psi}_L(x) \tag{41}
\]
Another one for the case of \( x < 0 \), the relations (40) can be rewritten as
\[
U^\dagger \psi_R(x) U = e^{i \theta_1} e^{-i \frac{\pi}{4}} \bar{\psi}_R(x) \tag{42}
\]
\[
U^\dagger \psi_L(x) U = \frac{1}{2} e^{i \theta_1} e^{i \frac{\pi}{4}} [(1 - e^{i 2 \delta}) \bar{\psi}_R(x) + (1 + e^{i 2 \delta}) \bar{\psi}_L(x)]
\]
The physical explanation of Eqs. (41) and (42) is that a right-moving electron from \(-\infty\) to \(+\infty\) and a left-moving electron from \(+\infty\) to \(-\infty\) are reflected at the impurity site \( x = 0 \). For a general phase shift \( \delta \), the right- and left-moving electrons are only partially reflected on the impurity. However, at the strong coupling critical points \( \delta^c = \pm \pi / 2 \), the right- and left-moving electrons are completely reflected on the impurity site. This can be easily shown from Eqs. (41) and (42)

\[
U^\dagger \psi_{R\sigma}(x) U|_{\delta^c} = \begin{cases} 
    e^{i \theta_1} e^{i \frac{\pi}{4}} \bar{\psi}_L(-x), & x > 0 \\
    e^{i \theta_1} e^{-i \frac{\pi}{4}} \bar{\psi}_R(x), & x < 0
\end{cases}
\]
\[
U^\dagger \psi_{L\sigma}(x) U|_{\delta^c} = \begin{cases} 
    e^{i \theta_1} e^{-i \frac{\pi}{4}} \bar{\psi}_L(x), & x > 0 \\
    e^{i \theta_1} e^{i \frac{\pi}{4}} \bar{\psi}_R(-x), & x < 0
\end{cases}
\]
(43)

It can be easily seen that there exists a relative phase shift \( \Delta \delta = \pi / 2 \) between in and out electron wave functions as the right- and left-moving electrons are completely reflected on the impurity site \( x = 0 \), which is different from the boundary conditions \( \psi_{R\sigma}(x, t) = \pm i \bar{\psi}_{L\sigma}(-x, t) \). Therefore, Eq. (43) means that at zero temperature this infinity one-dimensional system breaks into two half-infinity subsystems at the impurity site \( x = 0 \), but the electron fields have a twisted boundary condition. Eq. (43) is consistent with the calculation of the Green function of the fields \( \bar{\psi}_{1(2)\sigma}(x, t) \) at the strong coupling critical points \( \delta^c = \pm \pi / 2 \).
VI. FERMI-EDGE SINGULARITY FUNCTION OF X-RAY ABSORPTION

There is some debating about the Fermi-edge singularity of X-ray absorption because previous perturbation approximation calculations give different singularity exponents. Now we re-calculate the exponent of the Fermi-edge singularity function of X-ray absorption which is determined by the correlation function

\[ I_\sigma(t) = \langle e^{iH_1t} \psi_{1\sigma}^{\dagger}(0)e^{-i(H_1+H_{im})t}\psi_{1\sigma}(0) \rangle = \langle P(t)\tilde{\psi}_{1\sigma}^{\dagger}(0,t)U(t)U^\dagger(0)\tilde{\psi}_{1\sigma}(0,0) \rangle \]  

(44)

where \( P(t) = e^{iH_1t}e^{-i(H_1+\tilde{H}_2)t} \sim 1 \), and \( U(t) = e^{i(H_1+\tilde{H}_2)t}Ue^{-i(H_1+\tilde{H}_2)t} \). In order to calculate the correlation function (44), we need to know the correlation functions of the boson fields \( \Phi_{\pm s}(x,t) \) and \( \Phi_{\pm c}(x,t) \) near the impurity site \( x = 0 \), where \( \Phi_{\pm c}(x,t) = \frac{1}{2}\{[\Phi_{1\uparrow}(x,t) + \Phi_{1\downarrow}(x,t)] \pm [\Phi_{2\uparrow}(x,t) + \Phi_{2\downarrow}(x,t)]\}. \)

According to the Hamiltonians \( H_1 \) and \( \tilde{H}_2 \), the correlation functions of the boson fields \( \Phi_{+c(s)}(x,t) \) are completely determined by the Hamiltonian

\[ H' = \frac{\hbar v_c}{4\pi} \int dx[\partial_x \bar{\Phi}_{+c}(x)]^2 + \frac{\hbar v_s}{4\pi} \int dx[\partial_x \bar{\Phi}_{+s}(x)]^2 \]  

(45)

where \( \bar{\Phi}_{+c}(x) = \cosh(\chi_c)\Phi_{+c}(x) - \sinh(\chi_c)\Phi_{+c}(-x) \), and \( \bar{\Phi}_{+s}(x) = \cosh(\chi_s)\Phi_{+s}(x) - \sinh(\chi_s)\Phi_{+s}(-x) \), where the parameters \( \chi_c(s) \) are defined as \( \tanh(2\chi_c(s)) = \gamma_c(s) \). It is worth noting that the Hamiltonian (45) is independent of the impurity scattering. By simple calculation, we can obtain the correlation functions in the long time limit

\[ <e^{-i\Phi_{+c}(0,t)}e^{i\Phi_{+c}(0,0)}> \sim t^{-1/g_c} \]

\[ <e^{-i\Phi_{+s}(0,t)}e^{i\Phi_{+s}(0,0)}> \sim t^{-1/g_s} \]  

(46)

Using the Green functions \( G_{11(22)}(0,t;0,0) \) and Eq. (46), we can determine the correlation functions of the boson fields \( \Phi_{-c(s)}(0,t) \), because the fermion fields \( \bar{\psi}_{1(2)\sigma}(x) \) can be written as in terms of the boson fields \( \Phi_{\pm c}(x) \) and \( \Phi_{\pm s}(x) \)

\[ \bar{\psi}_{1(2)\sigma}(x) \sim \exp\{i\frac{1}{2}[\Phi_{+c}(x) \pm \Phi_{-c}(x) + \sigma\Phi_{+s}(x) \pm \sigma\Phi_{-s}(x)]\} \]  

(47)
Comparing the Green functions $G_{11}(22)(0,t;0,0)$ with Eq. (46), we can easily obtain the correlation functions in the long time limit

$$
\langle e^{-i\Phi_{-c}(0,t)} e^{i\Phi_{-c}(0,0)} \rangle \sim t^{-\bar{g}_c}
$$

$$
\langle e^{-i\Phi_{-s}(0,t)} e^{i\Phi_{-s}(0,0)} \rangle \sim t^{-\bar{g}_s}
$$

where $\bar{g}_{c(s)} = \sqrt{1 - \cos(2\delta)\gamma_{c(s)}}/\sqrt{1 + \cos(2\delta)\gamma_{c(s)}}$. Using Eqs. (46) and (48), we can obtain

$$
I_\sigma(\omega) \sim \omega^\kappa, \quad \kappa = -1 + \frac{1}{4} (\frac{1}{\bar{g}_c} + \frac{1}{\bar{g}_s}) + (1 - \frac{2|\delta|}{\pi})^2 \bar{g}_c + \bar{g}_s.
$$

It is noting that the exponent of the Fermi-edge singularity function depends on the phase shift $\delta$, therefore the impurity scattering influences its low energy behavior. At the strong coupling critical points $\delta_c^c = \pm \pi/2$, the exponent $\kappa$ takes the value $\kappa_c = -1 + \frac{1}{4\bar{g}_c} + \frac{1}{2\bar{g}_s}$. For the interaction-free case, $g_c = g_s = 1$, it takes $\kappa_c = -1/4$. For the spinless repulsive interacting fermion system ($V_2 = 0, g_c = g_s = g$, and $\bar{g}_c = \bar{g}_s$), using the same method as above, at the strong coupling critical points $\delta_c^c = \pm \pi/2$ we can easily obtain $\kappa_c = -\frac{7}{8} + \frac{1}{2g}$. For a free spinless fermion system, $g = 1$, the $\kappa_c$ is $-3/8$. This Fermi-edge singularity should be seen in future experiment. These results at $\delta_c^c = \pm \pi/2$ are the same as that in Ref. [3–6], and different from that in Ref. [7] for the interaction-free case. In these two cases, for small repulsive interaction of the electrons, i.e., $g \sim 1$ (spinless), or $g_c \sim g_s \sim 1$, there is the Fermi-edge singularity produced by the backward scattering of the deep core-level hole. However, a stronger repulsive interaction of electrons will sweep off (i.e., $\kappa \geq 0$) the Fermi-edge singularity induced by the backward scattering of the deep core-level hole.

VII. FRIEDEL OSCILLATION AND CHARGE NEUTRALITY

This is another important issue of the impurity scattering in one-dimensional system which shows new character different from that in high dimensional system, where the impurity can be a point-like testing charge. Now we take the following impurity scattering Hamiltonian
\[ H_{im} = U(0) \sum_\sigma [\rho_{R\sigma}(0) + \rho_{L\sigma}(0)] \]
\[ + U(2k_F)[\psi_{R\sigma}^\dagger(0)\psi_{L\sigma}(0) + \psi_{L\sigma}^\dagger(0)\psi_{R\sigma}(0)] \]  

(50)

where \( U(0) = Q_{test}(V_1 + V_2) \) is usual forward scattering potential, \( U(2k_F) = Q_{test}V_{2k_F} \) is the backward scattering potential and \( Q_{test} \) is a test charge residing at \( x = 0 \). Now the unitary transformation \( U \) is replaced by the following one

\[ \bar{U} = \exp\{i \sum_\sigma \{ \frac{g_v \tilde{\delta}}{2\pi} [\Phi_{1\sigma}(0) + \Phi_{2\sigma}(0)] + \frac{\delta}{2\pi} [\Phi_{1\sigma}(0) - \Phi_{2\sigma}(0)] \} \} \]  

(51)

where the phase shifts \( \tilde{\delta} \) and \( \delta \) are defined as \( \tilde{\delta} = \arctan\left[ \frac{U(0)}{\bar{\psi}R\sigma(x)} \right] \), and \( \delta = \arctan\left[ \frac{U(2k_F)}{\bar{\psi}L\sigma(x)} \right] \). It must be reminded that the forward scattering does not alter the interaction among electrons, therefore the Green functions of electrons we obtained remain invariant after including the forward scattering term.

The total density field of electrons reads

\[ \rho(x) = \frac{1}{2} \sum_\sigma [\rho_{R\sigma}(x) + \rho_{L\sigma}(x)] \]
\[ + \frac{1}{2} \sum_\sigma [\psi_{R\sigma}^\dagger(x)\psi_{L\sigma}(x) + e^{i2k_Fx}\psi_{L\sigma}^\dagger(-x)\psi_{R\sigma}(x)] \]  

(52)

In terms of the electron fields \( \bar{\psi}_{R(L)}\sigma(x) \), we can easily obtain the relations which describe the influence of the impurity scattering on the electron density field

\[ \rho_{>}(x) = \bar{U}^\dagger \rho(x \geq 0) \bar{U} \]
\[ = \frac{g_v}{\pi} \delta(x) + \frac{1}{2} \sum_\sigma [\beta \bar{\rho}_{R\sigma} + \bar{\rho}_{L\sigma}(x) + \alpha \bar{\rho}_{L\sigma}(-x)] \]
\[ + \frac{i}{4} \sin(2\delta) \left[ \psi_{R\sigma}^\dagger(\bar{\psi}_{L\sigma}(-x) - \psi_{L\sigma}(x)] \right]  
\[ + \frac{1}{2} \left[ \left( \cos(\delta) \psi_{R\sigma}^\dagger(x) \bar{\psi}_{L\sigma}(x) - i \sin(\delta) \psi_{L\sigma}^\dagger(\bar{\psi}_{R\sigma}(x) + e^{-i2k_Fx-ig_v\bar{\delta}} + h.c. \right) \right] \]  

(53)

\[ \rho_{<}(x) = \bar{U}^\dagger \rho(x < 0) \bar{U} \]
\[ = \frac{1}{2} \sum_\sigma [\beta \bar{\rho}_{L\sigma}(x) + \bar{\rho}_{R\sigma}(x) + \alpha \bar{\rho}_{R\sigma}(-x)] \]
\[ + \frac{i}{4} \sin(2\delta) \left[ \psi_{L\sigma}^\dagger(\bar{\psi}_{R\sigma}(x) - \psi_{R\sigma}(x)] \right]  
\[ + \frac{1}{2} \left[ \left( \cos(\delta) \psi_{L\sigma}^\dagger(x) \bar{\psi}_{R\sigma}(x) + i \sin(\delta) \psi_{R\sigma}^\dagger(x) \bar{\psi}_{R\sigma}(x) + e^{-i2k_Fx+ig_v\bar{\delta}} + h.c. \right) \right] \]  

(54)
At the strong coupling critical points $\delta^c = \pm \pi/2$, using the Green functions of the electron fields $\bar{\psi}_{R(L)\sigma}(x)$, we can easily obtain the electron density

$$<\rho^c_>,<(x) > \sim \cos\left(\frac{2k_F x \pm g_c \tilde{\delta}}{x(g_c+g_s)/2}\right)$$

which shows the unusual Friedel oscillation different from that in high dimensional system.

The total charge induced by the testing charge $Q_{test}$ can be obtained

$$Q^c = \int dx <\rho^c_>,<(x) U^\dagger \rho(x) U >$$

$$= -\frac{g_c \tilde{\delta}}{\pi} - a \int_0^\infty dx \frac{\sin(g_c \tilde{\delta}) \sin(2k_F x) + \cos(g_c \tilde{\delta}) \cos(2k_F x)}{x(g_c+g_s)/2}$$

where $a$ is a constant, and we have chosen $\sum_{\sigma} \int dx [\bar{\rho}_{R\sigma}(x) + \bar{\rho}_{L\sigma}(x)] = 0$. In the case of $\tilde{\delta} \sim 0$, i.e., weak forward scattering, $Q^c$ can be rewritten as

$$Q^c = -(1 - g_c^2)Q_{test}[1 + a\pi \int_0^\infty dx \frac{\sin(2k_F x)}{x(g_c+g_s)/2}] - a \int_0^\infty dx \frac{\cos(2k_F x)}{x(g_c+g_s)/2}$$

The last term derives from the backward scattering, because we have taken the phase shift $\delta^c = \pm \pi/2$ (corresponding to $Q_{test}U(2k_F) \to \pm \infty$), it is independent of the testing charge $Q_{test}(\neq 0)$. The charge neutrality means that the relation is rigorously satisfied, $Q^c = Q_{test}$. However, Eq. (57) shows that $Q^c$ depends on some parameters such as the bandwidth and the size of the system. Therefore, the conduction electrons cannot completely screen the test charge. Some boundary charge is needed to retain the charge neutrality of the system. This conclusion is consistent with the previous calculation [30].

VIII. IMPURITY SUSCEPTIBILITY OF MAGNETIC IMPURITY SCATTERING

The magnetic impurity scattering described by the Kondo interaction term, which is different from the non-magnetic impurity scattering, we cannot use the unitary transformation $U'$ (16) completely to eliminate the Kondo interaction term. The spin-exchange interaction term $\bar{H}_K$ (18) determines the low energy behavior of the magnetic impurity. Here we only consider the low temperature dependence of the impurity susceptibility which is completely
determined by the two phase shifts $\bar{\delta}$ and $\delta$. For simplicity, we use a spinless fermion to represent the magnetic impurity spin, $S^- = f$, $S^+ = f^\dagger$, and $S^z = f^\dagger f - 1/2$, the Hamiltonian $\bar{H}_K$ (58) can be written as

$$\bar{H}_K = K_1[\Psi^\dagger(0)f + f^\dagger\Psi(0)] + K_2[\bar{\Psi}^\dagger(0)f + f^\dagger\bar{\Psi}(0)]$$

where $K_1(2) = J_{1(2)} \left( \frac{D}{2\pi\hbar v_F} \right)^{1/2}$, $\Psi(0) = \left( \frac{D}{2\pi\hbar v_F} \right)^{1/2} e^{-i(1+2\bar{\delta}/\pi)\Phi_s(0)} e^{-i(1+2\delta/\pi)\Phi_s(0)}$ and $\bar{\Psi}(0) = \left( \frac{D}{2\pi\hbar v_F} \right)^{1/2} e^{-i(1+2\bar{\delta}/\pi)\Phi_s(0)} e^{i(1-2\delta/\pi)\Phi_s(0)}$ are anyon fields which anticommute with the fermion field $f$. Now we consider three regions determined by the phase shifts $\bar{\delta}$ and $\delta$ under the condition $g_s(c) \leq 1$, i.e., for the repulsive interacting electron system.

**A. The case of $\bar{\delta} \sim 0$ and $\delta \sim \pm \pi/2$**

In these regions, the physical property of the system is completely determined by the Hamiltonian at the critical fixed points $\bar{\delta} = 0$ and $\delta^c = \pm \pi/2$. The Hamiltonian $\bar{H}_K$ (58) can be rewritten as at these critical fixed points

$$\bar{H}_K = K[\chi^\dagger(0)f + f^\dagger\chi(0)]$$

where $K = K_1$ and $\chi(0) = \Psi(0)$ for $\delta = -\pi/2$, and $K = K_2$ and $\chi(0) = \bar{\Psi}(0)$ for $\delta = \pi/2$. We have neglected the term with high conformal dimension. According to Eqs. (46) and (59), we can obtain the Green function of the impurity fermion $f$

$$< f^\dagger(\omega)f(-\omega) > \sim \frac{1}{i\omega - \Sigma(\omega)}, \quad \Sigma(\omega) \sim |\omega|^{-1+1/g_s}$$

If $g_s = 1$, i.e., the interaction-free electron system, the self-energy of the impurity fermion $\Sigma(\omega)$ becomes a constant, the system becomes usual one-channel Kondo problem. If $g_s < 1/2$, i.e., the strong interaction system, the exponent of the self-energy is larger than one, $-1+1/g_s > 1$, in the low energy limit the self-energy only contributes higher order correction, therefore it can be neglected, the impurity becomes free. However, If $1/2 \leq g_s < 1$, the low energy behavior of the impurity is determined by the self-energy $\Sigma(\omega)$. Based upon above discussion, we can obtain the low temperature dependence of the impurity susceptibility.
\[
\chi_{\text{im}}(T) \sim \begin{cases} 
\text{const.}, & g_s = 1 \\
T^{3-2/g_s}, & 1/2 \leq g_s < 1 \\
T^{-1}, & g_s < 1/2 
\end{cases}
\]  

Only in the interaction range \(1/2 < g_s < 1\), the exponent of the impurity susceptibility depends on the interaction among electrons. In the strong interaction limit, the impurity becomes free.

**B. The case of \(\bar{\delta} \sim -\pi/2\) and \(\delta \sim \pm \pi/2\)**

In these regions, the low energy physical property of the impurity is determined by the Hamiltonian \(\bar{H}_K\) at the critical fixed points \(\bar{\delta}^c = -\pi/2\) and \(\delta^c = \pm \pi/2\)

\[
\bar{H}_K = K[\chi^\dagger(0)f + f^\dagger\chi(0)]
\]

where \(\chi(0) = (\frac{D}{2\pi \hbar v_F})^{1/2} \exp\{i(1 - g_s)\Phi_+(0)\}\) has the conformal dimension \((1 - g_s)^2/(2g_s)\).

For the interaction-free case, \(g_s = 1\), the excitation spectrum of the impurity fermion opens a gap proportional to \(K\) due to the interaction term \((62)\). In the case of \(g_s < 1\), we can obtain the self-energy of the impurity fermion at these critical fixed points

\[
\Sigma(\omega) \sim |\omega|^{1+(1-g_s)^2/g_s}
\]

and the low temperature dependence of the impurity susceptibility

\[
\chi_{\text{im}}(T) \sim \begin{cases} 
T^{3-2(1-g_s)^2/g_s}, & \bar{g} \leq g_s < 1 \\
T^{-1}, & g_s < \bar{g} 
\end{cases}
\]

where the parameter \(\bar{g}\) is determined by the equation \((1 - \bar{g})^2 = 2\bar{g}\).

**C. The case of \(\bar{\delta} \sim -\pi/2\) and \(\delta \sim 0\)**

The low energy behavior of the system in this region is determined by the Hamiltonian \(\hat{H}_K\) at the critical fixed point \(\bar{\delta}^c = -\pi/2\) and \(\delta = 0\)

\[
\hat{H} = K_1[\chi^\dagger(0)f + f^\dagger\chi(0)] + K_2[\bar{\chi}^\dagger(0)f + f^\dagger\bar{\chi}(0)]
\]

where \(\chi(0) = (\frac{D}{2\pi \hbar v_F})^{1/2} \exp\{i(1 - g_s)\Phi_+(0) + i\Phi_- (0)\}\) and \(\bar{\chi}(0) = (\frac{D}{2\pi \hbar v_F})^{1/2} \exp\{i(1 - g_s)\Phi_+(0) - i\Phi_- (0)\}\). For the interaction-free case, \(g_s = 1\), we have the relation \(\chi(0) = \bar{\chi}(0)\).
The system becomes usual asymmetric two-channel Kondo model if $K_1 \neq K_2$. It is worth noting that the $\bar{\delta} = -\pi/2$ and $\delta = 0$ is not a stable critical fixed point, because for the repulsive interaction system ($g_s(c) < 1$) the backward scattering $J_{2k_F}^\pm$-term has the conformal dimension $(g_c + g_s)/2 < 1$, it is relevant in terminology of renormalization group. The backward scattering potential $J_{2k_F}^\pm$ is renormalized to infinity in low energy limit, which corresponds to the phase shift $\delta^c = \pm\pi/2$. However, here we artificially assume that the backward scattering potential is very small at some low energy region so that we can discuss some low energy behavior of the impurity near the point $\delta = 0$.

In the case of $g_s = 1$, the system becomes usual two-channel Kondo problem. If $K_1 = K_2$, the low temperature dependence of the impurity susceptibility is $\chi_{im}(T) \sim \ln(T)$. If $K_1 \neq K_2$, the asymmetry of the two channels destroys the $\ln(T)$ dependence of the impurity susceptibility and makes it show the low temperature behavior of one-channel Kondo problem $[32]$. In the case of $g_s < 1$, the self-energy of the impurity fermion consists of two parts, one is contributed directly by the anyon fields $\chi(0)$ and $\bar{\chi}(0)$, and another one is from their hybridization,

$$
\Sigma_1(\omega) \sim (K_1^2 + K_2^2)|\omega|^{(1-g_s)^2/g_s+g_s-1}
$$

$$
\Sigma_2(\omega) \sim K_1K_2|\omega|^{(1-g_s)^2/g_s-g_s-1}
$$

(66)

It can be seen that in the range $1/4 < g_s < 1$, the impurity susceptibility has the power law temperature dependence in the low temperature region. However, in the strong interaction region $g_s < 1/4$, the impurity spin becomes free, the impurity susceptibility shows the low temperature behavior $1/T$. It is worth noting that in the three different regions $A, B$ and $C$, they all show that in the strong repulsive interaction region the impurity spin becomes free, which is the most prominent character of magnetic impurity scattering in one-dimensional electron system. These results are consistent with previous calculation for a magnetic impurity scattering in Heisenberg chain $[33]$. The physical explanation of the low temperature power-law behavior of the impurity susceptibility is that the impurity scattering suppresses the density of state of electrons near the impurity site for the repulsive interacting electron.
system, therefore the impurity spin is only partially screened, which is similarly to the non-magnetic impurity scattering case where the testing charge $Q_{\text{test}}$ is partially screened by conduction electrons.

The impurity susceptibilities in (61) and (64) are different from that in Ref.[11]. The result in Ref.[11] was obtained by taking the way that for $J_2 = 0$ (here we use present labels) and $V_1 = V_2 = 0$ the system becomes the usual one-channel Kondo problem, it is well-known that it has an infrared Fermi liquid fixed point, then they assumed that after switching electron interaction, as $\{V_1, V_2\} \to 0$ the system has the same infrared fixed point as the one-channel Kondo problem. This assumption is crucial, and its correctness is unclear. First, for an one-dimensional interacting electron system, the forward scattering potential is not generally equal to the backward scattering one because they satisfy different renormalization group equations in the low energy limit. Second, for an interaction-free electron system, the backward scattering term induced by the magnetic impurity is marginal, but for a repulsive interaction electron system, the backward scattering term is relevant, the interaction-free system has an infrared fixed point different from that of the interaction system. Generally, there does not exist a principle to guarantee that there is a smooth connection between these two infrared fixed points as the interaction potentials $V_1$ and $V_2$ go to zero.

**IX. CONCLUSION AND DISCUSSION**

Combining the basic path integral and bosonization methods, we have studied the low energy behavior of the magnetic and non-magnetic impurity scattering in an one-dimensional repulsive interacting electron system (Tomonaga-Luttinger liquid), and discussed some basic and controversial issues in this topics. Due to the linearization of the excitation spectrum of electrons near their two Fermi levels, using the factorization Ansatz we have exactly calculated the Green functions of electrons $\tilde{\psi}_{R(L)\sigma}(x)$ and fermions $\tilde{\psi}_{1(2)\sigma}(x)$ for a general phase shift $\delta$ induced by the backward scattering potential of the impurity. The influence of the backward scattering on the system is great, because the backward scattering alters the
interaction among electrons and makes the exponents of all but density-density correlation functions depend on the phase shift $\delta$. This is the most prominent character of the backward scattering in Tomonaga-Luttinger liquid.

Due to the backward scattering term is relevant, any perturbation expansion method is hard to give a rigorous description for the system from weak to strong backward scattering, therefore it is not surprised that there are some controversial issues in this topics, such as the density of state of electrons near and far away from the impurity site, the exponent of the Fermi-edge singularity function of X-ray absorption, the low temperature behavior of the impurity susceptibility, the boundary conditions of electron fields at zero temperature on impurity site, and so on. However, by using the simple unitary and global gauge transformations, the backward scattering term can be rigorously treated, and its influence on the system is incorporated to the interaction terms among electrons, then using path integral method all correlation functions we needed can be exactly calculated. Therefore, we believe that our results are correct, and can be used to justify previous results obtained by other methods.

The most important properties of the impurity scattering in Tomonaga-Luttinger liquid are that: a). At zero temperature the electrons are completely reflected on the impurity site $x = 0$, the system breaks into two subsystems at $x = 0$ but the right- and left-moving electron fields have the twisted boundary condition. b). The density of state of electrons is suppressed near the impurity site, but it mainly remains invariance as far away from the impurity. c). The exponents of correlation functions, such as the Green functions of electrons $\bar{\psi}_{R(L)\sigma}(x)$ and fermions $\bar{\psi}_{1(2)\sigma}(x)$, depend upon the phase shift $\delta$ induced by backward scattering. d). In the low energy limit, the testing charge is only partially screened by the conduction electrons. e). In the weak repulsive interaction region, the impurity susceptibility has the power-law low temperature dependence. In the strong repulsive interaction region, the impurity spin becomes free, and the impurity susceptibility has the $1/T$-type low temperature behavior.
