Defluviitalea raffinosedens sp. nov., a thermophilic, anaerobic, saccharolytic bacterium isolated from an anaerobic batch digester treating animal manure and rice straw

Shichun Ma,†‡ Yan Huang,†‡ Cong Wang,§ Hui Fan,† Liu Dong,†‡ Zheng Zhou,†‡ Xing Liu,†‡ and Yu Deng†‡,*

Abstract

A thermophilic, anaerobic, fermentative bacterium, strain A6ᵀ, was obtained from an anaerobic batch digester treating animal manure and rice straw. Cells were Gram-stain-positive, slightly curved rods with a size of 0.6–1.2 x 2.5–8.2 µm, non-motile and produced terminal spores. The temperature, pH and NaCl concentration ranges for growth were 40–60 °C, 6.5–8.0 and 0–15.0 g l⁻¹, with optimum growth noted at 50–55 °C, pH 7.5 and in the absence of NaCl, respectively. Yeast extract was required for growth. D-Glucose, maltose, D-xylene, D-galactose, D-fructose, D-ribose, lactose, raffinose, sucrose, D-arabinose, cellulose, D-mannose and yeast extract were used as carbon and energy sources. The fermentation products from glucose were ethanol, lactate, acetate, propionate, butyrate, valerate, iso-butyrate, iso-valerate, H₂ and CO₂. The G+C content of the genomic DNA was 36.6 mol%. The predominant fatty acids were C₁₂:0, iso-C₁₇:0 3-OH. Respiratory quinones were not detected. The polar lipid profile comprised phosphoglycolipids, phospholipids, glycolipids, a diphosphatidylglycerol, a phosphatidylglycerol and an unidentified lipid. Phylogenetic analyses of the 16S rRNA gene sequence indicated that the strain was closely related to Defluviitalea saccharophila DSM 22681ᵀ with a similarity of 96.0%. Based on the morphological, physiological and taxonomic characterization, strain A6ᵀ is considered to represent a novel species of the genus Defluviitalea, for which the name Defluviitalea raffinosedens sp. nov. is proposed. The type strain is A6ᵀ (=DSM 28090ᵀ = ACCC 19951ᵀ).

An anaerobic digestion is a method of waste treatment aimed at reducing the hazardous effects of wastes on the biosphere [1]. It comprises complex, redox biochemical reactions driven by various anaerobic and relatively anaerobic microorganisms, resulting in the decomposition of complex organic substances into simple compounds (mainly CH₄ and CO₂) [2]. Since the beginning of the use of culture-independent techniques, increasing numbers of ecological studies have indicated that the phylum Firmicutes is one of the predominant and widespread bacterial groups in various anaerobic digesters [3–6]. It is well known that groups of the order Clostridiales in the phylum Firmicutes (such as Clostridium, Acetivibrio, Selenomonas and Ruminococcus) are some of the most common hydrolytic bacteria in anaerobic bioreactors, especially in cellulytic environments [7–11]. Defluviitaleaceae, belonging to the order Clostridiales of the phylum Firmicutes, was erected by Jabari [12] to describe thermophilic, anaerobic, Gram-positive, rod-shaped, non-motile, terminal-spore-forming and saccharolytic bacteria. Defluviitalea saccharophila LIND6LT2ᵀ was isolated from an upflow anaerobic digester treating waste water, and was assigned as the type species of the family Defluviitaleaceae.

We collected samples from an anaerobic batch digester treating animal manure and rice straw, which was pre-enriched with PY medium (2 g peptone and 1 g yeast extract per litre distilled water) containing rice straw (5 g per litre distilled water), and a microbial consortium degrading rice straw under anaerobic methanogenic conditions at 40 °C was obtained and subcultured for 10 years. The 16S rRNA clone libraries and high-throughput sequencing analyses revealed that Clostridium, Gracilibacter, Sedimentibacter...
and uncultured *Firmicutes* were the predominant organisms of the microbial consortium (unpublished data). To reveal the ecophysiological roles of anaerobic bacteria in anaerobic digestion, strain A6<sup>T</sup> was enriched and isolated from the above-mentioned microbial consortium at 55 °C using enriched medium (basal medium containing 1 g yeast extract and 5 g sodium acetate or 3 g sodium propionate). The basal medium contained the following (per litre distilled water): NH<sub>4</sub>Cl, 1.0 g; yeast extract, 0.1 g; L-Cys-HCl, 1 g; 0.1 % (w/v) resazurin solution, 1.0 ml; macro mineral solution, 50.0 ml; trace mineral solution, 10.0 ml; and vitamin mix solution, 10.0 ml. The macro mineral solution, trace mineral solution and vitamin mix solution were prepared as described previously [13]. The agar medium was supplemented with 18.0 g agar. All the media were prepared and dispensed anaerobically under a gaseous atmosphere of 100 % N<sub>2</sub>. The pH of the medium was adjusted to 6.5–7.0 with 5 M KOH, and the media were sterilized by autoclaving at 121 °C for 30 min.

The enriched medium was inoculated with 2 % (v/v) rice straw-degrading microbial consortium and incubated for 1 week at 55 °C. For isolation, the enrichment culture was serially diluted tenfold in Hungate tubes containing molten agar medium, and the tubes were rolled following the procedures of the Hungate roll-tube technique [14–16]. Subsequently, single colonies were picked and transferred into liquid medium under anaerobic conditions. The roll-tube procedure was repeated several times until a pure culture was obtained. A single white and round colony was obtained and designated as strain A6<sup>T</sup>. This strain did not utilize acetate or propionate, but grew at low cell concentration in enriched medium, indicating that the yeast extract in the medium served as carbon and energy source during enrichment and isolation. For subsequent incubation of strain A6<sup>T</sup>, D-glucose was used as the main substrate, instead of acetate or propionate. The taxonomic description of strain A6<sup>T</sup> is reported here based on phenotypic and phylogenetic studies.

The extraction and purification of DNA, PCR amplification and sequencing of the 16S rRNA were performed as described by Huang [17]. The sequence obtained was submitted to NCBI for initial alignment with highly similar sequences in the BLASTN program. The 16S rRNA sequences from closely related organisms were retrieved from NCBI and EzTaxon. Phylogenetic trees were reconstructed with the software package MEGA version 5.0 using the neighbour-joining and maximum-likelihood methods [18]. The robustness of the topology in the phylogenetic tree was evaluated by bootstrap analysis based on 1000 replicates. Phylogenetic analysis based on the 16S rRNA gene sequence revealed that strain A6<sup>T</sup> belonged to the family *Defluvitaleaceae*, and that its closest relative was *D. saccharophilica* LIND6LT2<sup>T</sup> (96 % sequence similarity), followed by *Natrananaerovirga pectinivora* AP3<sup>T</sup> (88.9 %), *Vallitalea guaymasensis* Ra1766G1<sup>T</sup> (88.4 %), *Lactonifactor longoviformis* ED-Mt61/PGY-s6<sup>T</sup> (88.3 %) and *Anaerostipes butyraticus* LMG 24724<sup>T</sup> (88.11 %) (Fig. 1).

The cultural and morphological characteristics of the isolated strain A6<sup>T</sup> were investigated using cells cultivated on basal carbonate yeast extract and trypticase medium (BCTY medium). The BCTY medium consisted of basal medium, yeast extract (0.5 g l<sup>-1</sup>) and trypticase (0.5 g l<sup>-1</sup>). Prior to inoculation, filter-sterilized glucose solution was added as substrate (final concentration 5 g l<sup>-1</sup>) to the sterile BCTY medium. Cell morphology was examined using a scanning electron microscope (JEOL JSM-7500F) and transmission electron microscope (Hitachi H-600IV). Gram staining was performed using the traditional method [19] and spore staining was performed conventionally [20]. The presence of spores and Gram staining were observed using a phase-contrast microscope (Nikon 80i).

---

**Fig. 1.** Neighbour-joining phylogenetic tree based on 16S rRNA gene sequences showing the relationship between strain A6<sup>T</sup> and its phylogenetically close relatives. The GenBank/EMBL/DDBJ accession number for the 16S rRNA gene sequence of strain A6<sup>T</sup> is KF766957 (1413 bp). Bar, 0.02 changes per nucleotide position.
D. saccharophila DSM 22681<sup>T</sup> was obtained from the Deutsche Sammlung von Mikroorganismen und Zellkulturen GmbH (DSMZ) for comparison of its physiological and chemotaxonomic characteristics with those of strain A6<sup>T</sup>. Growth experiments to determine the pH, temperature and NaCl concentration ranges were performed in triplicate using Hungate tubes with 5 ml of BCTY medium containing glucose as the substrate. The pH range examined for growth was 5.5–10.0, and was adjusted using the following sterile anaerobic solutions (20 mM): MES (5.5, 6.0), PIPES (6.5, 7.0, 7.5), HEPES (8.0), Tricine (8.5) and CHES (9.0, 9.5, 10.0). The temperature range investigated was 35–65°C at 5°C intervals, and the NaCl concentration range was 0–25.0 g NaCl l<sup>−1</sup>. Substrate utilization tests were performed in basal medium with D-glucose, D-xylene, maltose, D-fructose, D-galactose, D-ribose, D-sucrose, D-lactose, D-mannose, D-mannitol, raffinose, L-rhamnose, cellobiose, D-arabinose, yeast extract, acetate, propionate, pyruvate and lactate. Each substrate was added at a final concentration of 20 mM (for sugars and organic acids). The strain was subcultured at least twice under the same experimental conditions prior to determination of growth rates. Elemental sulfur (1 %, w/v), sulfate (20 mM), thiosulfate (20 mM), sulfite (2 mM), nitrate (10 mM) and nitrite (2 mM) were tested as terminal electron acceptors. Growth was determined by measuring the turbidity of the cultures at a wavelength of 600 nm using a spectrophotometer (DU 730; Beckmann) as described previously [12].

The liquid fermentation products were determined by GC (Agilent 7890A) using an FFAP column (30 m×320 μm×0.25 μm) and a flame ionization detector with N<sub>2</sub> as the carrier gas at a flow rate of 36 ml min<sup>−1</sup>. H<sub>2</sub> and CO<sub>2</sub> were analysed by GC (Agilent 7820A) using a porapak Q packed column (2 m×30 μm) and thermal conductivity detector with N<sub>2</sub> as the carrier gas at a flow rate of 30.0 ml min<sup>−1</sup> and column temperature of 80°C. H<sub>2</sub>S production was determined photochemically as described by Cord-Ruwisch [21]. Sulfate, nitrate and nitrite were measured by ion chromatography (Dionex ICS-3000) using an IonPac AG12A column with 2.7 mM Na<sub>2</sub>CO<sub>3</sub> and 0.3 mM NaHCO<sub>3</sub> as eluent at a flow rate of 1.2 ml min<sup>−1</sup>.

Strain A6<sup>T</sup> formed white and round colonies after 2 days at 55°C. Cells were non-motile and slightly curved rods with a size of 2.5–7.6×1–0.58 μm, occurring singly or in pairs (Fig. 2). Furthermore, the strain was Gram-stain-positive and formed spores at high temperature. The temperature, pH and NaCl concentration ranges for growth of the strain were 40–65°C (optimum 50°C), 6.5–8.0 (optimum 7.5) and 0–20 % (w/v) (optimum 0 %), respectively (Fig. S1, available in the online Supplementary Material). The maximum growth rate of the strain was 0.58 h<sup>−1</sup> when glucose was used as the substrate in BCTY medium under the above-mentioned optimum conditions.

It is noteworthy that the addition of yeast extract enhanced growth of strain A6<sup>T</sup>. Similar to D. saccharophila LIND6LT2<sup>T</sup>, growth of strain A6<sup>T</sup> was improved with increasing concentrations of yeast extract. Elemental sulfur, thiosulfate, sulfate, sulfite and nitrate were not used as electron acceptors. While the strain was able to ferment D-glucose, maltose, D-xylene, D-galactose, D-fructose, D-ribose, D-lactose, raffinose, sucrose, D-arabinose, cellobiose, D-mannose and yeast extract, it could not utilize D-mannitol, L-rhamnose, peptone, acetate, propionate, pyruvate or lactate. Moreover, cellulose was not hydrolysed by strain A6<sup>T</sup>. The fermentation products of the strain in a saccharide-utilizing culture were H<sub>2</sub>, CO<sub>2</sub>, ethanol, lactate, acetate, propionate, butyrate, valerate, traces of iso-butyrate, and iso-valerate.

The DNA G+C content, cellular fatty acid composition, respiratory quinones and polar lipids were evaluated by the Identification Service of the DSMZ (Braunschweig, Germany). The DNA G+C content was determined by using HPLC as described by Mesbah et al. [22]. The cellular fatty acid composition was determined by saponification, methylation and extraction as described earlier with minor modifications [23, 24]. Fatty acids were analysed using the Sherlock MIS system (MIDI). Respiratory quinones were extracted using methanol/

hexane [25, 26], followed by phase separation into hexane. Respiratory lipoquinones were separated by TLC on silica gel (Macherey-Nagel Art. No. 805023), using hexane/tetrabutylmethylether (9:1, v/v) as the solvent and further analysed by HPLC. Polar lipids were extracted using chloroform/methanol/0.3% aqueous NaCl mixture (1:2:0.8, by vol.) and separated by two-dimensional silica gel TLC (Macherey-Nagel Art. No. 18135). The total lipid content was detected using the method described by Tindall et al. [27].

The major whole-cell fatty acids of strain A6T were C16:0 (30.6%), iso-C17:1 (30.3%), C14:0 (18.1%), C16:1ω7c (5.6%), C16:0 N-alcohol (3.2%), C13:0 3-OH (2.9%), C13:1 AT 12–13 (1.0%), C18:0 (0.8%), C12:0 (0.7%), C18:1ω7c (0.4%), C16:1ω5c (0.3%), C18:1ω9c (0.3%) and an unknown component (5.7%) (Table 1). Respiratory quinones were not detected. The polar lipid profile comprised phosphoglycolipids, phospholipids, glycolipids, a diphosphatidylglycerol and a phosphatidylglycerol (Fig. S2). The DNA G+C content of strain A6T was 36.6 mol%, which is similar to that of D. saccharophila LIND6LT2T (35.2 mol%) [12].

Although strain A6T was found to be phenotypically comparable to D. saccharophila LIND6LT2T with respect to cell morphology, optimum pH and temperature for growth, electron acceptors, and polar lipid profile, it differed with respect to major cellular fatty acids and substrate utilization. Unlike D. saccharophila LIND6LT2T, strain A6T did not ferment D-mannitol or L-rhamnose, but fermented D-galactose, D-fructose, D-ribose, lactose, raffinose and D-arabinose

The G+C content. In addition, strain A6<sup>T</sup> could be easily distinguished from <i>N. pectinivora</i>, <i>V. guaymasensis</i>, <i>L. longoviformis</i> and <i>A. butyraticus</i> by growth temperature and DNA G+C content. In addition, strain A6<sup>T</sup> and <i>N. pectinivora</i> could also be differentiated based on the utilization of pectin.

Therefore, based on the data from phylogenetic, physiological and chemotaxonomic analyses, strain A6<sup>T</sup> can be considered to represent a novel species of the genus <i>Defluvitalae</i>, belonging to the family <i>Defluvitalaceae</i>, order <i>Clostridiales</i>, and phylum <i>Fiircutes</i>, for which we propose the name <i>Defluvitalae raffinosedens</i> sp. nov.

**DESCRIPTION OF DEFLUVITALAE RAFFINOSEDENS SP. NOV**

<i>Defluvitalae raffinosedens</i> (raf.fi.nos.e’dens. N.L. neut. n. raffinosum raffinose; L. pres. part. eddies eating; N.L. part. adj. raffinosedens raffinose-eating).

Cells are Gram-stain-positive, slightly curved rods with a size of 2.5–7.6 μm, non-motile, occur singly or in pairs, and form spores at high temperature. Growth occurs at 40–65 °C (optimum 50 °C), pH 6.5–8.0 (optimum 7.5) and an NaCl concentration of 0–20% (w/v). Cells are thermophilic and anaerobic, and hydrolyse d-glucose, maltose, d-xylose, d-galactose, d-fructose, d-ribose, lactose, d-mannose, raffinose, sucrose, d-arabinose, cellobiose and yeast extract. Yeast extract is required for growth. The major cellular fatty acids are C<sub>16:0</sub>, iso-C<sub>17:1</sub>, C<sub>14:0</sub>, C<sub>16:1ω7c</sub>, C<sub>16:0</sub> N-alcohol and C<sub>13:0</sub> 3-OH. Respiratory quinones are not found. The polar lipids are phosphoglycolipids, phospholipids, glycolipids, a diphosphatidylglycerol and a phosphatidylglycerol.

The type strain is A6<sup>T</sup> (=DSM 28090<sup>T</sup>=CC19 19951<sup>T</sup>), isolated from an anaerobic batch digester treating animal manure and rice straw. The G+C content of the genomic DNA of the type strain is 36.6 mol%.

Int J Syst Evol Microbiol 2010;60:1108–1112.

Five reasons to publish your next article with a Microbiology Society journal

1. The Microbiology Society is a not-for-profit organization.
2. We offer fast and rigorous peer review – average time to first decision is 4–6 weeks.
3. Our journals have a global readership with subscriptions held in research institutions around the world.
4. 80% of our authors rate our submission process as ‘excellent’ or ‘very good’.
5. Your article will be published on an interactive journal platform with advanced metrics.

Find out more and submit your article at microbiologyresearch.org.
