| 21 (outward)                  | -1091.44       | -1.13  |

U = gas phase energy (AMBER’s ff14SB), W = solvation energy (GB geometry optimizations with PBSA single-point energy corrections) His157 CA, CB, CG and CD2 were fixed while conformational searching was applied to all other VM2 ‘live’ atoms.

Methodology for generation of His157 “inward” to “outward” energy path.

Initial morphing conformations. The Morph Conformations capability in UCSF Chimera,1,2 with rigid corkscrew interpolation, was used to generate an initial set of conformations that morph between the lowest free energy “inward” and “outward” NcLPMO9D monomer conformations produced by VM2. (See the section: Mining minima (VM2) free energy calculations, Figure 9, for VM2 NcLPMO9D calculation details.) A total of 21 NcLPMO9D monomer conformers were generated, including conformer 1 corresponding to “inward” His157 and conformer 21 corresponding to “outward” His157.
Relaxed energy path using VM2. Each of the initial morphing conformations, generated via rigid interpolation, was then used to initiate a constrained VM2 conformational search, where the His157 CA, CB, CG and CD2 atoms were fixed in space, but all other atoms in the VM2 live set were allowed to move, generating a reaction path that allowed for relaxation of the NcLPMO9D structure during the His157 inward/outward flip. The lowest energy, i.e., the gas phase plus solvation energy (U+W), conformation found for each of the 21 constrained VM2 conformational searches was taken as a structure on the reaction path. The energies (U+W) and relative energies along this reaction path are reported in Table S1. The details of the forcefield and solvation treatment, as well as protein ‘cutout’ model, were identical to those used for the original VM2 free energy calculations reported in the main paper. (Note that we do not report VM2 free energies for the reaction path, as currently only U+W is available in VM2 calculations when there are live atoms fixed in space.)
**Supplementary Figures**

**Figure S1.** VM2 calculated relative energies, $\Delta(U+W)$, for reaction coordinate pathway from His157 inward to outward conformation. See Table S6 and description of methodology for transition reaction coordinate and path energy generation above.
Figure S2. DFT active site model and convergence behavior of superoxo species bound with His157 NE2-protonated. The starting and ending structures are shown as insets.
Figure S3. DFT active site model and convergence behavior of hydroperoxyl species bound with His157 deprotonated. The starting and ending structures are shown as insets.
Figure S4. DFT active site model and convergence of hydroperoxo species bound after 1 electron reduction with His157 deprotonated. The starting and ending structures are shown as insets.
Figure S5. DFT active site model and convergence behavior of hydroperoxo species bound after 2 electron reduction with His157 deprotonated. The starting and ending structures are shown as insets.
Figure S6. X-ray structure of LPMO9D His157 Molecule A after direct exposure to acidic conditions. Structural alignment of LPMO9D Molecule A neutron diffraction data collected at pH 4.4/pD 4.8 using vapor exchange (coral) with an X-ray diffraction dataset of Molecule A following a direct pH 4.4/pD 4.8 soak (blue) and X-ray diffraction of the resting state of LPMO9D Molecule B (PDB 5TKG) at pH 6.0 (magenta). H atoms displayed in white and D atoms displayed in turquoise.
Figure S7. X-ray structure of LPMO9D His157 Molecule B after direct exposure to acidic conditions. Structural alignment of LPMO9D Molecule B neutron diffraction data collected at pH 4.4/pD 4.8 using vapor exchange (light green) with an X-ray diffraction dataset of Molecule B following a direct pH 4.4/pD 4.8 soak (purple) and X-ray diffraction of the resting state of LPMO9D Molecule B (PDB 5TKG) at pH 6.0 (yellow). H atoms displayed in white and D atoms displayed in turquoise.
