Abstract: We consider the problem of testing significance of predictors in multivariate nonparametric quantile regression. A stochastic process is proposed, which is based on a comparison of the responses with a nonparametric quantile regression estimate under the null hypothesis. It is demonstrated that under the null hypothesis this process converges weakly to a centered Gaussian process and the asymptotic properties of the test under fixed and local alternatives are also discussed. In particular we show, that - in contrast to the nonparametric approach based on estimation of $L^2$-distances - the new test is able to detect local alternatives which converge to the null hypothesis with any rate $a_n \rightarrow 0$ such that $a_n\sqrt{n} \rightarrow \infty$ (here $n$ denotes the sample size). We also present a small simulation study illustrating the finite sample properties of a bootstrap version of the corresponding Kolmogorov-Smirnov test.

Keywords and phrases: Nonparametric quantile regression, significance testing, empirical processes, monotone rearrangement.

Received June 2012.

1. Introduction

Nonparametric regression methods have become very popular in the last decades because of the fact that employing a mis-specified parametric model will typically result in inconsistent estimates and as a consequence invalid statistical
inference. In recent years many authors have developed nonparametric quantile regression estimates, which provide an attractive supplement to least squares methods by focussing on the estimation of the conditional quantiles instead of the mean function [see Chaudhuri (1991), Yu and Jones (1997), Yu and Jones (1998), Dette and Volgushev (2008), Chernozhukov et al. (2010) or Bondell et al. (2010), among many others]. These references mainly discuss the case of a one dimensional predictor, but from a theoretical point of view the methods can easily be generalized to multivariate predictors. On the other hand it is well known that in practical applications such nonparametric methods suffer from the curse of dimensionality and therefore do not yield precise estimates of conditional quantile surfaces for realistic sample sizes. In such cases a natural and very important question is which predictor variables are significant.

The problem of testing significance has found considerable interest in multivariate mean regression models. Gozalo (1993) considered conditional moment tests, while Yatchew (1992) constructed a test based on semi-parametric least-squares residuals. Lavergne and Vuong (1996) suggested a directional testing procedure for discriminating between two sets of regressors without specifying the functional form of the mean regression, and Racine (1997) proposed a test based on nonparametric estimates of the partial derivatives of the conditional mean of the response. Lavergne and Vuong (2000) used the kernel method to develop a test for the significance of a subset of explanatory variables and Delgado and González-Manteiga (2001) proposed a test which is based on functionals of a $U$-process.

Because of the well known robustness properties of the conditional quantile and the fact that conditional quantiles characterize the entire distribution it is of particular interest to develop methods for testing significance of predictors in quantile regression models. Surprisingly, in quantile regression this problem has found much less attention. Variable selection in the framework of linear quantile regression models has been recently considered by Zou and Yuan (2008), Wu and Liu (2009) and Belloni and Chernozhukov (2011), among others. Jeong et al. (2012) proposed a test for significance in a multivariate quantile regression model. The work of these authors was motivated by Granger quantile causality [Granger (1969)] and they employed an idea of Zheng (1998), who proposed to transform quantile restrictions to mean restrictions. The corresponding test is based on a $U$-statistic, which estimates the distance measure

$$
\Delta = E[(P(Y \leq q_\tau(X)|X,Z) - \tau)^2 f_Z(Z)],
$$

(1.1)

where $Y$ denotes the response, $(X,Z)$ is the predictor, $f_Z$ the density of $Z$ and $q_\tau(X)$ the conditional $\tau$-quantile of $Y$ given $X$. Note that the quantity $\Delta$ vanishes if and only if the conditional quantile of $Y$ given $X$ and $Z$ does not depend on $Z$. A major drawback of this approach lies in the fact that nonparametric smoothing over both $X$ and $Z$ is needed for the construction of the estimate. This implies that the test is of very limited use when the dimension of $(X,Z)$ is larger than 3. Moreover, this test can only detect local alternatives converging to the null hypothesis $H_0 : \Delta = 0$ at a rate $n^{-1/2}h^{-(d+q)/4}$, where $d$
and $q$ are the dimensions of the predictors $X$ and $Z$, respectively, and $h$ denotes a bandwidth converging to 0 with increasing sample size $n$.

The present paper is devoted to the problem of constructing a test for the hypothesis of the insignificance of the predictor $Z$, i.e., $\Delta = 0$, in the nonparametric quantile regression model, which can detect local alternatives converging to the null hypothesis at a parametric rate and at the same time does not depend on the dimension of the predictor $Z$, such that smoothing with respect to the covariate $Z$ can be avoided. To be precise, the test proposed in this paper can detect alternatives converging to $H_0$ at any rate $a_n \to 0$ such that $a_n \sqrt{n} \to \infty$, where $n$ denotes the sample size. Our approach is based on an empirical process $T_n(x, z)$, which estimates the functional

$$T(x, z) = E[(Y \leq q_\tau(X)) - \tau I\{X \leq x\} I\{Z \leq z\}]$$

for all $(x, z)$ in the support of the distribution of the predictor $(X, Z)$, where the inequality $X \leq x$ between the vectors $X$ and $x$ is understood as the vector of inequalities between the corresponding coordinates and $I\{A\}$ denotes the characteristic function of the event $A$. The model, necessary notation and definition of this process are introduced in Section 2 and a stochastic expansion of the process $T_n(x, z)$ is established in Section 3. This result allows us to obtain the weak convergence of an appropriately scaled and centered version of $T_n(x, z)$ under the null hypothesis, fixed and local alternatives. As a result we obtain a Kolmogorov-Smirnov or a Cramer von Mises type statistic for the hypothesis of the significance of the predictor $Z$ in the nonparametric quantile regression model. Moreover, we are also able to extend the result to the case, where the dimension $q$ of the predictor $Z$ is growing with the sample size, that is $q = q_n \to \infty$ as $n \to \infty$. The finite sample properties of a corresponding bootstrap test are investigated in Section 4. As a by-product of our theoretical analysis we also obtain new results on the uniform convergence of the conditional quantile estimator proposed by Dette and Volgushev (2008). Finally all proofs, which are complicated, are deferred to an Appendix in Section A, whereas Section B contains some technical results and Section C a sketch for validity of the bootstrap procedure.

2. Model, assumptions and test statistic

Let $Y$, $X$ and $Z$ denote one-, $d$ and $q$ dimensional random variables, respectively, where $Y$ corresponds to the response and $X$ and $Z$ are the covariates. We assume that the random variables $\{(Y_i, X_i, Z_i)\}_{i=1,...,n}$ are independent identically distributed with the same distribution as $(Y, X, Z)$. Let $\tau \in (0, 1)$ be fixed. Our aim is to test whether the predictor $Z$ has influence on the conditional $\tau$-quantile of $Y$, given $(X, Z)$, or whether the variable $Z$ can be omitted. Note that this problem fundamentally differs from the question whether $Y$ is independent of $Z$ given $X$. In fact, the latter is equivalent to testing whether all quantile curves do not depend on $Z$ as opposed to looking at a particular quantile. Thus for
fixed \( \tau \in (0, 1) \) we formulate the null hypothesis as

\[
H_0 : E[I\{Y \leq q_\tau(X)\} - \tau \mid X, Z] = P(Y \leq q_\tau(X) \mid X, Z) - \tau = 0 \quad \text{a.s.,} \tag{2.1}
\]

where \( q_\tau(X) \) is defined as the conditional \( \tau \)-quantile of \( Y \), given \( X \), that is

\[
P(Y \leq q_\tau(X) \mid X) = \tau. \tag{2.2}
\]

It is easy to see that the null hypothesis (2.1) is equivalent to

\[
T(x, z) \equiv 0
\]

for all \((x, z)\) in the support of the random variable \((X, Z)\), where the functional \( T \) is defined in (1.2). This functional can be be estimated by the stochastic process

\[
T_n(x, z) = \frac{1}{n} \sum_{i=1}^{n} (I\{Y_i \leq \hat{q}_\tau(X_i)\} - \tau) I\{X_i \leq x\} I\{Z_i \leq z\}, \tag{2.3}
\]

where \((x, z) \in R_X \times R_Z, R_X \) and \( R_Z \) denote the support of the distributions of the random variables \( X \) and \( Z \), respectively, and \( \hat{q}_\tau \) is an appropriate estimate of the conditional quantile of \( Y \) given \( X \), which will be specified below. A test for the hypothesis of significance of the variable \( Z \) for the \( \tau \)th quantile curve of \( Y \) can now easily be obtained by considering a Kolmogorov-Smirnov or Cramer von Mises type statistic based on \( T_n \) and rejecting the null hypothesis for large values of this statistic. Throughout this paper we assume that the sets \( R_X \) and \( R_Z \) are compact.

In the literature, several non-parametric quantile regression estimators have been proposed [see e. g. Yu and Jones (1997, 1998), Takeuchi et al. (2006), Chernozhukov et al. (2010) or Bondell et al. (2010), among others]. In this paper we will use an approach proposed by Dette and Volgushev (2008) who constructed non-crossing estimates of quantile curves using a simultaneous inversion and isotonization of a preliminary estimator of the conditional distribution function \( F_{Y \mid X} \) of \( Y \) given \( X \). For this estimator, say \( \hat{F}_{Y \mid X}(y \mid x; p) \), we will use a smoothed local polynomial estimator of order \( p \), see e. g. Fan and Gijbels (1996). Before defining this estimator, it is necessary to introduce some notation.

- For \( d \)-dimensional vectors \( x = (x(1), \ldots, x(d)) \in \mathbb{R}^d \) and \( k = (k(1), \ldots, k(d)) \in \mathbb{N}_0^d \) define

\[
x^k := (x(1)^{k(1)}, \ldots, x(d)^{k(d)}), \quad \pi(x) := x(1) \cdot x(2) \cdot \ldots \cdot x(d)
\]

\[
\sigma(k) := k(1) + \cdots + k(d), \quad k! := k(1)! \cdot \cdots \cdot k(d)!
\]

- For \( d \)-dimensional vectors \( x \in \mathbb{R}^d \), \( k \in \mathbb{N}_0^d \) and a function \( K : \mathbb{R} \to \mathbb{R} \) define

\[
K(x) := \prod_{j=1}^{d} K(x(j)), \quad K_{h_n,k}(x) := K(x/h_n) \pi((x/h_n)^k)
\]

\[
K^{(m)}(x) := \prod_{j=1}^{d} K^{(m(j))}(x(j)), \quad K^{(m)}_{h_n,k}(x) := K^{(m)}(x/h_n)
\]
where \( \mathbf{m} = (m_1 \ldots m_d) \) is a \( d \)-dimensional vector with entries from \( \mathbb{N}_0 \) and \( K^{(\ell)} \) is the \( \ell \)th derivative of a function \( K \).

- Define \( N_j := \# \{ k \in \mathbb{N}_0^d \mid \sigma(k) = j \} \) as the number of distinct \( d \)-tuples with size \( j \), and denote the elements of this set by \( k_{1,m}, \ldots, k_{N_{m,m}} \).

With these notational conventions the local polynomial estimator \( \hat{F}_{Y|X}(y|x; p) \) of order \( p \) can be represented as [see e.g. Fan and Gijbels (1996)]

\[
\hat{F}_{Y|X}(y|x; p) := e_1'(X'WX)^{-1}X'WY,
\]

where \( e_1 \) denotes a vector of suitable dimension with first entry one and remaining entries zero, the matrices \( X, W \) and the vector \( Y \) are given by

\[
X = \begin{pmatrix}
1 & (x - X_1)^{k_1,1} & \ldots & (x - X_1)^{k_{N_i,1}} & \ldots & (x - X_1)^{k_{N_p-p,1}} \\
\vdots & \vdots & \ddots & \vdots \ddots & \vdots \\
1 & (x - X_n)^{k_1,1} & \ldots & (x - X_n)^{k_{N_i,1}} & \ldots & (x - X_n)^{k_{N_p-p,1}}
\end{pmatrix},
\]

\[
W = \frac{1}{nh_{i,n}^t} \text{Diag}(\mathbf{K}_{h_n,0}(x - X_1), \ldots, \mathbf{K}_{h_n,0}(x - X_n)),
\]

\[
Y := \left( \Omega \left( \frac{y - Y_1}{d_n} \right), \ldots, \Omega \left( \frac{y - Y_n}{d_n} \right) \right)^t,
\]

and \( \Omega \) denotes a smoothed version of the indicator function \( I\{ \cdot \leq 0 \} \), that is

\[
\Omega(v) = \int_{-\infty}^{v} \omega(u) du
\]

for a given kernel \( \omega \) with support \([-1, 1]\). Following Dette and Volgushev (2008) we consider a strictly increasing distribution function \( G : \mathbb{R} \to (0, 1) \), a nonnegative kernel \( \kappa \) with bandwidth \( b_n \), and define the functional

\[
H_{G,\kappa,\tau,b_n}(F) := \frac{1}{b_n} \int_0^1 \int_{-\infty}^{\tau} \kappa \left( \frac{F(G^{-1}(u)) - v}{b_n} \right) dv du.
\]

If \( \hat{F}_{Y|X} \) is the estimator of the conditional distribution function defined in (2.4), it is intuitively clear that \( H_{G,\kappa,\tau,b_n}(\hat{F}_{Y|X}(\cdot|x)) \) is a consistent estimate of \( H_{G,\kappa,\tau,b_n}(F_{Y|X}(\cdot|x)) \). If \( b_n \to 0 \), this quantity can be approximated as follows

\[
H_{G,\kappa,\tau,b_n}(F_{Y|X}(\cdot|x)) \approx \int_\mathbb{R} I\{F_{Y|X}(y|x) \leq \tau\} dG(y)
\]

\[
= \int_0^1 I\{F_{Y|X}(G^{-1}(v)|x) \leq \tau\} dv = G \circ F_{Y|X}^{-1}(\tau|x),
\]

and as a consequence an estimate of the conditional quantile function \( q_{\tau}(x) = F_{Y|X}^{-1}(\tau|x) \) can be defined by

\[
\hat{q}_{\tau}(x) := G^{-1}(H_{G,\kappa,\tau,b_n}(F_{Y|X}(\cdot|x))).
\]

Throughout this paper, we will assume that the kernels, the function \( G \) and the bandwidth parameters used to build the estimator satisfy the following conditions.
In the Appendix. In particular, these findings
are needed in the theoretical developments to exclude “residuals”

(K1) The kernel \( K \) has support \([-1,1]\) and is \( p + 1 \geq d + 2 \) times continuously
differentiable with uniformly bounded derivatives. Additionally the first
\( p + 1 \) derivatives of \( K \) vanish at the boundary points \(-1\) and \( 1 \).

(K2) The function \( \omega \) in (2.6) is a kernel of order \( s \geq d + 1 \), has support \([-1,1]\)
and is \( d \) times continuously differentiable. Additionally \( \omega \) has uniformly
bounded derivatives that vanish at the boundary points \(-1\) and \( 1 \).

(K3) The kernel \( \kappa \) is symmetric, positive with support \([-1,1]\) and has one
Lipschitz-continuous derivative.

(K4) \( G : \mathbb{R} \to [0,1] \) is a strictly increasing distribution function such that
\( G, G^{-1} \) are two times continuously differentiable.

(K5) \( d_n^{2s} + h_n^{p+1} = o(1/\sqrt{n}) \) and \( \log n/(n h_n^{3d+2}) + \log n/(n h_n^d d_n^{d-1}) = o(1) \)

(K6) \( \log n/n h_n^d b_n = o(1), \ b_n^2 + \log n/n h_n^d b_n + b_n(\log n)^{3/2}/\sqrt{n h_n^d} = o(1/\sqrt{n}) \)

Remark 2.1. Dette and Volgushev (2008) demonstrate that the choice of the
distribution function \( G \) has a negligible impact on the quality of the resulting
estimate provided that an obvious centering and standardization is performed.
Similarly, the estimate \( \hat{q}_r(x) \) is robust with respect to the choice of the band-
width \( b_n \) if it is chosen sufficiently small [see Dette et al. (2006)].

Remark 2.2. Dette and Volgushev (2008) only established point-wise weak
convergence of their estimator. However, for most applications such as the con-
struction of tests on the basis of this estimator, uniform results are needed.

In the following discussion it turns out to be advantageous to consider a
generalization of the test statistic \( T_n \) defined in (2.3), where the indicator
functions \( I\{X_i \leq x\} \) are replaced by indicators of more general sets \( \Theta \). To
be precise let \( \Xi \) denote a collection of subsets of \( \mathbb{R}^d \) and define \( D_n := \{ x \in R_X| x - h_n 1, x + h_n 1 \} \subset R_X \} \) (here \( 1 \) denotes the \( d \)-dimensional vector with
all entries equal to 1), then all theoretical developments will be based on the statistic

\[
T_n(\Theta, z) = \frac{1}{n} \sum_{i=1}^{n} (I\{Y_i \leq \hat{q}_r(X_i)\} - \tau)I\{X_i \in \Theta \cap D_n\}I\{Z_i \leq z\}, \quad (2.9)
\]

where \( \Theta \in \Xi, z \in R_Z \). The intersection of the sets \( \Theta \in \Xi \) with the set \( D_n \)
is needed in the theoretical developments to exclude “residuals” \( I\{Y_i \leq \hat{q}_r(X_i)\} - \tau \)
corresponding to predictors close to the boundary of \( R_X \). In what follows, we
will use the abbreviation \( \Theta_n := \Theta \cap D_n \). Note that if \( \cup_{\Theta \in \Xi} \Theta \) has a positive
distance to the boundary of \( R_X \), the collection of sets \( \Xi_n := \cup_{\Theta \in \Xi} \Theta_n \) will equal \( \Xi \) whenever \( h_n \) is sufficiently small. Note also that we use the same symbol \( T_n \)
for the processes in (2.3) and (2.9) but the meaning is always clear from the
class.
Additionally to its advantages from a theoretical point of view, the consideration of a collection of sets that are more general than sets defined by indicators of rectangles will for example allow to investigate the problem of testing the significance of the variable \( Z \) on a certain subset, say \( S \subset R_X \), that is

\[
H_0^S : E[I\{Y \leq q_\tau(X)\}I\{X \in S\} | X, Z] = P(Y \leq q_\tau(X), X \in S | X, Z) = \tau P(X \in S) \tag{2.10}
\]

Note that \( H_0^S \) means that the conditional \( \tau \)-quantile of \( Y \) given \( (X, Z) \) can be represented as a function \( q_\tau(X) \) for \( X \in S \subset R_X \). In this case a natural choice for the collection \( \Xi \) is given by \( \Xi := \{(-\infty, t] \cap S | t \in \mathbb{R}^d \} \), but other choices are of course possible as well.

3. Main asymptotic results

In this section we investigate the asymptotic properties of the stochastic process defined in (2.9). For this purpose we need some additional notation and technical assumptions which are collected here for convenience and for later reference.

Define the ‘error’ variables as \( \varepsilon = Y - q_\tau(X) \) and \( \varepsilon_i = Y_i - q_\tau(X_i) \), \( i = 1, \ldots, n \). We assume that the conditional distribution function \( F_{\varepsilon|X}(\cdot|x) \) of \( \varepsilon \) given \( X = x \) has a density, say \( f_{\varepsilon|X}(y|x) \). Note that by definition we have that \( F_{\varepsilon|X}(0|x) = P(\varepsilon \leq 0|X) = \tau \). In particular, this identity continues to hold even if the null hypothesis is violated. Throughout this paper we denote by \( F_{Z|X,\varepsilon}(\cdot|x,e) \) the conditional distribution function of \( Z \) given \( (X, \varepsilon) = (x,e) \).

Define \( D := \bigcup_{\Theta \in \Xi} \Theta \), then we assume that the data-generating process satisfies the following conditions.

(A1) The conditional distribution function \( F_{Y|X}(y|x) \) is \( p+1 \) times continuously differentiable with respect to \( x, y \) and all partial derivatives are uniformly bounded on \( R_X \times \mathbb{R} \). The joint density of \( (X, Y) \) is uniformly bounded on \( R_X \times \mathbb{R} \). Moreover, \( p \geq \max(s, d + 1) \).

(A2) The density \( f_X \) of the predictor \( X \) is \( d + 1 + n_f \) times continuously differentiable with uniformly bounded partial derivatives on \( R_X \) and \( n_f > d/2 \). Moreover \( \inf_{x \in R_X} f_X(x) > 0 \).

(A3) There exist constants \( a, C_1 \) such that

\[
\inf_{(x,y):x \in R_X, |y - q_\tau(x)| \leq a} f_{Y|X}(y|x) \geq C_1.
\]

(A4) The function \( (z, x) \mapsto F_{Z|X,\varepsilon}(z|x,0) \) is H"older-continuous of order \( \gamma > 0 \) with respect to \( z \) and \( x \) uniformly in \( x \in D \), i.e.

\[
|F_{Z|X,\varepsilon}(s|x,0) - F_{Z|X,\varepsilon}(t|\xi,0)| \leq C\|(s, x) - (t, \xi)\|_\infty
\]

for some finite constant \( C \).

(A5) \( \sup_{x \in D, y \in \mathbb{R}, z \in R_Z} |f'_{\varepsilon|X,\varepsilon}(y | x, z)| < \infty \).
In conditions (A1)-(A4), \( R_X \) can be replaced by a set \( \mathcal{X} \subset R_X \) provided that \( \mathcal{D} \subset \mathcal{X} \). Finally, the following assumptions on the collection of sets \( \Xi \) are required.

(S1) The bracketing numbers of class of functions \( \mathcal{F}_1 = \{ u \mapsto I\{ u \in \Theta \} | \Theta \in \Xi \} \) satisfy \( N_{\mathcal{F}_1}(\mathcal{F}_1, \varepsilon, L^2(P_X)) \leq C \varepsilon^{-a} \) for any sufficiently small \( \varepsilon > 0 \) and a constant \( C \), where \( N_{\mathcal{F}_1} \) denotes the bracketing number [see van der Vaart and Wellner (1996)].

(S2) \( \sup_{\Theta \in \Xi} P(X_i \in \Theta, \exists j : [X_i(j) - h_n, X_i(j) + h_n] \not\subset \Theta) = o(1) \) for \( h_n \to 0 \).

**Remark 3.1.** Conditions (S1) and (S2) are not strong and for example satisfied for the collection of rectangles \( \Xi = \{ [s \leq X \leq t] | s, t \in \mathbb{R}^d \} \) if \( X \) has a uniformly bounded density with compact support. For more details on bracketing numbers and their properties we refer to the monograph of van der Vaart and Wellner (1996).

The following result gives a stochastic expansion of the process \( T_n(\Theta, z) \) under general conditions, which is crucial for deriving the asymptotic properties of the process \( T_n \). In particular, observe that this representation continues to hold under the alternative.

**Theorem 3.2.** If the assumptions \((K1)-(K6), (A1)-(A5)\) and \((S1), (S2)\) are satisfied, the process \( T_n \) can be represented as

\[
T_n(\Theta, z) = \frac{1}{n} \sum_{i=1}^{n} (I\{ \varepsilon_i \leq 0 \} - \tau) I\{ X_i \in \Theta \cap D_n \} (I\{ Z_i \leq z \} - F_{Z|X,\varepsilon}(z|X_i,0)) + o_P(n^{-1/2})
\]

uniformly with respect to \( z \in R_Z, \Theta \in \Xi \).

The proof of Theorem 3.2 is complicated and is given in the Appendix. As an immediate consequence, we obtain that under the null hypothesis \( H_0 \) the rescaled process \( \sqrt{n}T_n(\Theta, z) \) converges weakly to a centered Gaussian process.

**Corollary 3.3.** If the assumptions of Theorem 3.2 and the null hypothesis \( H_0 \) in (2.1) are satisfied, the process \( \sqrt{n}T_n \) converges weakly in \( \ell^\infty(\Xi \times R_Z) \) to a centered Gaussian process \( T \) with covariance kernel

\[
k(\Theta_1, \Theta_2, z) = \text{Cov}(T(\Theta_1, y), T(\Theta_2, z)) = \tau (1 - \tau) E \left[ I\{ X \in \Theta_1 \cap \Theta_2 \} \right]
\]

\[
\times E \left[ \left( I\{ Z \leq y \} - F_{Z|X,\varepsilon}(y|X,0) \right) \left( I\{ Z \leq z \} - F_{Z|X,\varepsilon}(z|X,0) \right) \right] X, \varepsilon \right] .
\]

As a consequence of this result we obtain the weak convergence of functionals such as the Kolmogorov-Smirnov statistic

\[
K_n = \sup_{\Theta \in \Xi} \sup_{z \in R_Z} |T_n(\Theta, z)|
\]

by an application of the continuous mapping theorem. In general the asymptotic distribution of \( K_n \) depends on certain features of the data generating process.
and in the following section we will discuss bootstrap approximations for this distribution. However, in some special cases the situation simplifies substantially.

**Remark 3.4.** In the case where the pair \((X, \varepsilon)\) and the covariate \(Z\) are independent it follows from (3.2) that

\[
\text{Cov}(\mathbb{T}(\Theta_1, y), \mathbb{T}(\Theta_2, z)) = \tau (1 - \tau) P(I\{X \in \Theta_1 \cap \Theta_2\})(F_Z(y \wedge z) - F_Z(y)F_Z(z)),
\]

where \(F_Z\) is the distribution function of the random variable \(Z\) and \(y \wedge z\) denotes the vector of minima of the corresponding coordinates of \(y\) and \(z\). If additionally \(X, Z\) are real-valued and \(\Xi = \{(-\infty, t) | t \in \mathbb{R}\}\), the asymptotic covariance in Theorem 3.2 reduces to

\[
\text{Cov}(\mathbb{T}((-\infty, t], y), \mathbb{T}((-\infty, s], z)) = \tau (1 - \tau) F_X(s \wedge t)(F_Z(y \wedge z) - F_Z(y)F_Z(z)).
\]

Hence, for univariate independent covariates \(X\) and \(Z\) with continuous distribution functions \(F_X\) and \(F_Z\), respectively, the Kolmogorov-Smirnov test is asymptotically distribution-free because in this case the statistic

\[
\sqrt{n} \sup_{x \in X, z \in Z} |T_n(x, z)| = \sqrt{n} \sup_{s, t \in [0, 1]} |T_n(F_X^{-1}(s), F_Z^{-1}(t))|
\]

converges in distribution to \(\sqrt{\tau (1 - \tau)} \sup_{s, t \in [0, 1]} |B(s, t)|\), where \(B\) is the Kiefer-Müller process on \([0, 1]^2\), i.e., a centered Gaussian process with covariance kernel

\[
\text{Cov}(B(s_1, t_1), B(s_2, t_2)) = (s_1 \wedge s_2)(t_1 \wedge t_2 - t_1t_2).
\]

The result obtained in Theorem 3.2 can also be used to derive the asymptotic properties of the test statistic under fixed alternatives. More precisely, the following result holds (note that under the null hypothesis, the centering term is zero, and thus this result is a generalization of Corollary 3.3).

**Corollary 3.5.** Under the assumptions of Theorem 3.2 the process

\[
\sqrt{n} \left( T_n(\Theta, z) - \int_{(R_X \cap \Theta_n) \times R_Z} \left( F_{Y|X,Z}(q_t(u)|u, v) - \tau \right) I\{v \leq z\} dF_{X,Z}(u, v) \right)
\]

converges weakly to the limiting process \(\mathbb{T}\) defined in Corollary 3.3.

**Remark 3.6.** A further consequence of Corollary 3.5 is that the statistic \(T_n(\Theta, z)\) converges for all \(\Theta \in \Xi\) and \(z \in R_Z\) in probability to the function

\[
\int_{(R_X \cap \Theta) \times R_Z} \left( F_{Y|X,Z}(q_t(u)|u, v) - \tau \right) I\{v \leq z\} - F_{Z|X,Z}(z|u, 0) dF_{X,Z}(u, v).
\]

Consequently, if \(\Xi\) contains sufficiently many sets (for example, if \(\Xi = \{(-\infty, x] | x \in \mathbb{R}^d\}\)), the test is consistent. In order to obtain the asymptotic distribution of the test statistic under local alternatives of the form

\[
F_{Y|X,Z}^{(n)}(q^{(n)}_\tau(u)|u, v) = \tau + a_n h(u, v)
\]

(3.3)
a result on the asymptotic behavior of $T_n(\Theta, z)$ is required when the data are generated from triangular arrays. A closer look at the proofs in the appendix shows that such a result does indeed hold under suitable modifications of the conditions in Theorem 3.2. More precisely, assume that the joint distribution of $(X, Y, Z)$ depends on $n$ and that all the constants and bounds in conditions (A1)-(A5) and (S1)-(S2) hold uniformly in $n$. A closer look at the proof of Theorem 3.2 reveals that in this case

$$T_n(\Theta, z) = \frac{1}{n} \sum_{i=1}^{n} (I\{\varepsilon_i \leq 0\} - \tau) I\{X_i \in \Theta_n\} (I\{Z_i \leq z\} - F^{(n)}_{Z|X,\varepsilon}(z|X_i, 0))$$

$$+ o_P(n^{-1/2}) \quad (3.4)$$

Since all arguments are exactly the same as those used to establish Theorem 3.2, the details are omitted for the sake of brevity. As a consequence, we see that under local alternatives

$$T_n(\Theta, z) = T_n^{(1)}(\Theta, z) + T_n^{(2)}(\Theta, z) + o_P(n^{-1/2})$$

where

$$T_n^{(1)}(\Theta, z) := \frac{1}{n} \sum_{i=1}^{n} (I\{\varepsilon_i \leq 0\} - E[I\{\varepsilon_i \leq 0\}|X_i, Z_i]) I\{X_i \in \Theta_n\}$$

$$\times (I\{Z_i \leq z\} - F^{(n)}_{Z|X,\varepsilon}(z|X_i, 0)),$$

$$T_n^{(2)}(\Theta, z) := \frac{1}{n} \sum_{i=1}^{n} (I\{\varepsilon_i \leq 0\}|X_i, Z_i) - \tau) I\{X_i \in \Theta_n\}$$

$$\times (I\{Z_i \leq z\} - F^{(n)}_{Z|X,\varepsilon}(z|X_i, 0)).$$

Here, the superscript $(n)$ emphasizes that the corresponding quantities depend on $n$ since the data are assumed to come from a triangular array. Now standard arguments show that

$$\sup_{\Theta, z} \sqrt{n} T_n^{(1)}(\Theta, z) = O_P(1)$$

$$\sup_{\Theta, z} \sqrt{n} T_n^{(2)}(\Theta, z) = O_P(1).$$

Moreover,

$$ET_n^{(2)}(\Theta, z) = \int_{(R_X \cap \Theta_n) \times R_Z} \left( F^{(n)}_{Y|X,Z}(q^{(n)}_{\theta}(u)|u, v) - \tau \right) I\{v \leq z\} dF^{(n)}_{X,Z}(u, v).$$

In particular, this implies that the test will detect all local alternatives for which the quantity

$$S_n := \sqrt{n} \sup_{\Theta, z} |ET_n^{(2)}(\Theta, z)|$$

diverges to infinity. This is due to the fact that under both $H_0$ and local alternatives the order of the bootstrap statistic $\sup_{\Theta, z} \sqrt{n} T_n(\Theta, z)$ with $T_n^*$ defined in section 4 is of order $O_P(1)$ while in the setting described above the quantity $\sup_{\Theta, z} \sqrt{n} T_n(\Theta, z)$ diverges
to infinity. For example $S_n \to \infty$ in probability if $\Xi = \{-\infty, x\} \times \mathbb{R}^d$ and $F_{Y\mid X,z}(u\mid u, v) = \tau + a_n h(u, v)$ for some function $h$ that is not identically zero on $R_X \times R_Z$ and sequence $a_n$ with $a_n \sqrt{n} \to \infty$.

**Remark 3.7.** We now give a brief discussion of the properties of the proposed test statistic when alternatives of increasing dimension are considered, i.e. when the dimension of the predictor $Z$, say $q_n$, varies with $n$. Consider the additional assumption

$(Z)$ The $L^2$ covering numbers of the classes of functions

$$\{x \mapsto F_{Z|X,z}(z|x+s,0)| z \in R_Z, \|s\|_{\infty} \leq a\}$$

and $\{\xi \mapsto I(\xi \leq z)| z \in R_Z\}$ are bounded by $C_1(C_2/\varepsilon)^{k_n}$ for some finite constants $C_1, C_2$.

Note that assumption $(Z)$ holds with $k_n = q_n$ if for each $n$ the predictor $Z$ given $(X, \varepsilon)$ has a conditional density $f_{Z|X,z}$ that satisfies

$$\sup_z |f_{Z|X,z}(z|x_1, 0) - f_{Z|X,z}(z|x_2, 0)| \leq C\|x_1 - x_2\|$$

for a finite constant $C$ independent of $n$. Under assumptions (K1)-(K6), (A1)-(A3), (Z), (A5), (S1), (S2) it is possible to prove that

$$T_n(\Theta, z) = \frac{1}{n} \sum_{i=1}^{n} (I(\varepsilon_i \leq 0) - \tau)I(X_i \in \Theta_n) (I\{Z_i \leq z\} - F_{Z|X,z}(z|X_i, 0))$$

$$+ o_P\left(\frac{k_n}{n^{1/2}}\right),$$

uniformly with respect to $z \in R_Z, \Theta \in \Xi$. In particular, this result implies that

$$\sqrt{n} \left( T_n(\Theta, z) - \int_{(R_X \cap \Theta_n) \times R_Z} \left( F_{Y|X,Z}(q_r(u)|u, v) - \tau \right) I\{v \leq z\} dF_{X,Z}(u, v) \right)$$

is of order $O_P(k_n)$. Consequently, the test is able to detect local alternatives converging to the null hypothesis with any rate $a_n$, such that $\frac{a_n}{k_n} \sqrt{n} \to \infty$ when the sample size and dimension $k_n$ of $Z$ is increasing.

**Remark 3.8.** Jeong et al. (2012) investigated an alternative test for the hypothesis (2.1) based on ideas from Fan and Li (1996) in combination with a modification which was originally proposed by Zheng (1998). Their test is based on the statistic

$$J_n = \frac{1}{n(n-1)g_n} \sum_{i,j \neq j} L((Z_i - Z_j)/g_n)(I\{Y_i \leq \hat{q}_r(X_i)\} - \tau)(I\{Y_j \leq \hat{q}_r(X_j)\} - \tau)$$

where $L$ is a kernel and $g_n$ is a bandwidth converging to 0 with increasing sampling size. These authors claimed that a normalized version of this test statistic converges to a normal distribution. It should be pointed out here that
the proof in this paper is not correct. The basic argument of Jeong et al. (2012) consists in the statement that the fact
\[ \sup_x |q(x) - q(x)| \leq C_n \]
results in the estimate
\[ J_n U \leq J_n \leq J_n L, \]
where the statistics \( J_n U \) and \( J_n L \) are defined by
\[ J_n U = \frac{1}{n(n-1)g_n^d} \sum_{i \neq j} L((Z_i - Z_j)/g_n) \varepsilon_i U \varepsilon_j U, \]
\[ J_n L = \frac{1}{n(n-1)g_n^d} \sum_{i \neq j} L((Z_i - Z_j)/g_n) \varepsilon_i L \varepsilon_j L, \]
and \( \varepsilon_i U = I\{Y_i + C_n \leq q_{\tau}(X_i)\} - \tau, \varepsilon_i L = I\{Y_i - C_n \leq q_{\tau}(X_i)\} - \tau \) (see equation (A.11-3) in this paper). A simple calculation shows that this conclusion is not correct and in fact the inequality (3.6) does not hold. It turns out that the proof of Theorem 1 in Jeong et al. (2012) can not be corrected easily.

Even if the gap in the proof would be closed, the test of Jeong et al. (2012) still has two major drawbacks. First, it requires non-parametric smoothing with respect to the covariate \( Z \). Second, it can only detect local alternatives converging to the null hypothesis at a rate \( n^{-1/2}g_n^{-(d+q)/4} \) which is slower than the rate \( a_n n^{-1/2} \) for any \( a_n \to \infty \) detected by the test proposed in this paper and additionally depends on the dimension of the covariates.

4. Bootstrap and simulation results

In general the limit distribution derived in Theorem 3.2 depends on certain features of the data generating process which are difficult to estimate. For this reason we discuss in this section bootstrap methods that are suitable to mimic the distribution of test statistics based on \( T_n \) under the null hypothesis. Several residual wild bootstrap approximations have been proposed in the literature for quantile regression analysis [see Sun (2006) or Feng et al. (2011)]. However, the residual wild bootstrap does not yield a valid approximation of the limiting distribution in the present context because it does not lead to an expansion of the bootstrap process analogous to the one given for \( T_n \) in Theorem 3.2.

As alternative we consider the idea of process-based wild bootstrap as considered by Delgado and González-Manteiga (2001) or He and Zhu (2003). To this end let \( U_1, \ldots, U_n \) denote independent and uniformly in \([0,1]\) distributed random variables, independent of the original data \( Y_n = \{(Y_i, X_i, Z_i) | i = 1, \ldots, n\} \). Introduce Bernoulli random variables \( B_i = I\{U_i \leq \hat{\tau}\}, i = 1, \ldots, n, \) with success probability \( \hat{\tau} = \frac{\sum_{j=1}^n I\{\hat{\varepsilon}_j \leq 0\}}{n} \), where \( \hat{\varepsilon}_i = Y_i - q_{\tau}(X_i), i = 1, \ldots, n \). Define the bootstrap process as
\[ T_n(\Theta, z) = \frac{1}{n} \sum_{i=1}^n (B_i - \hat{\tau}) I\{X_i \in \Theta\} \left( I\{\hat{\varepsilon}_i \leq z\} - \hat{F}_{Z_i | X_i}(z|X_i, 0) \right), \]
where
\[ \hat{F}_{Z|X,x}(\cdot|x,y) = \frac{\sum_{j=1}^{n} I\{Z_j \leq \cdot\} L(\frac{X_j-x}{a}) N(\frac{\hat{\epsilon}_j-y}{e})}{\sum_{j=1}^{n} L(\frac{X_j-x}{a}) N(\frac{\hat{\epsilon}_j-y}{e})} \] (4.2)
denotes a kernel estimator for the conditional distribution \( \hat{F}_{Z|X,x}(\cdot|x,y) \). Here, \( L \) and \( N \) denote \( d \)- and one-dimensional kernel functions and \( a \) and \( e \) corresponding bandwidths converging to 0 with increasing sample size. Then, conditional on \( Y_n \), the process \( \sqrt{nT_n^*} \) converges weakly to the process \( T \) defined in Corollary 3.3 in probability (under suitable regularity conditions). A sketch of the proof is given in Appendix C.

In our numerical investigations, it turned out that the asymptotic representation (3.1) for the process defined in (2.3) is not very accurate for small sample sizes. For \( \Xi = \{(-\infty, x]|x \in \mathbb{R}^d\} \) we thus considered a slightly modified version of the process \( T_n \), that is
\[ \tilde{T}_n(x,z) = \frac{1}{n} \sum_{i=1}^{n} \left( I\{Y_i \leq \hat{q}_{\tau}(X_i)\} - \hat{\tau}\right) I\{X_i \leq x\} (I\{Z_i \leq z\} - \hat{F}_Z(z)) \]
where \( \hat{F}_Z(z) \) denotes the empirical distribution function of \( Z_1, \ldots, Z_n \). This process provided much better results for moderate sample sizes. As motivation for this approach, observe that under both the null hypothesis and the alternative, we have
\[ D_x := \frac{1}{n} \sum_{i=1}^{n} \left( I\{Y_i \leq \hat{q}_{\tau}(X_i)\} - \hat{\tau}\right) I\{X_i \leq x\} = o_P(n^{-1/2}), \quad \hat{\tau} = \tau + o_P(n^{-1/2}) \]
uniformly with respect to \( x \) as can be seen by taking a closer look at the proofs of the main results in the Appendix. Thus the additional correction term
\[ \delta_{x,z} := D_x \hat{F}_Z(z) + \frac{\hat{\tau} - \tau}{n} \sum_{i=1}^{n} I\{X_i \leq x\} I\{Z_i \leq z\} \]
vanishes asymptotically (uniformly with respect to \( x,z \)) under both the alternative and the null hypothesis. If, on the other hand, \( \delta_{x,z} \) is relatively large because the sample size is small, the correction term \( \delta_{x,z} \) induces an additional centering (the factor \( \hat{F}_Z(z) \) corresponds to the amount of non-zero indicators \( I\{Z_i \leq z\} \)).

The simulation results described below confirm that this is a sensible approach.

For the calculation of the test statistic
\[ \tilde{K}_n = \sup_{x,z} |\tilde{T}_n(x,z)| \] (4.3)
based on the process \( \tilde{T}_n \), we use local polynomial estimators of order two [see (2.4)]. The bandwidth \( h_n \) of this estimator is chosen as \( h_n := (\hat{\sigma}^2/2n)^{1/3/50} \) where \( \hat{\sigma}^2 \) denotes the variance estimate of Rice (1984) from the sample \( \{(X_i, Y_i)|i = \ldots \} \)
The bandwidths used in (2.5) and (4.2) are chosen as \( d_n = e = h_n \), while the choice of \( b_n \) in (2.7) is even less critical [see also Dette and Volgushev (2008)] and we use \( b_n = h_n^3 \). In fact, in the simulations it turned out that the power and size properties of the test are rather insensitive with respect to the bandwidth choice, see table 3 and related discussion in the next paragraph. The function \( \omega \) in (2.6) is chosen as \( \omega(x) := (15/32)(3 - 10x^2 + 7x^4)f(|x| \leq 1) \), which is a kernel of order 2 [see Gasser et al. (1985)]. The function \( \kappa \) in (2.7) is defined as Epanechnikov kernel while all other kernels are Gaussian kernels. For the choice of the distribution function \( G \) in (2.7) we follow the procedure described in Dette and Volgushev (2008) who suggested a normal distribution such that the 5% and 95% quantiles coincide with the corresponding empirical quantities of the sample \( Y_1, \ldots, Y_n \).

4.1. Simulation results

We simulate data from the location scale model

\[
Y_i = q_j(X_i, Z_i) + s_k(X_i, Z_i)\epsilon_i, \quad (4.4)
\]

\( j, k = 1, \ldots, 4 \) with the following quantile and scale functions

\[
\begin{align*}
q_1(x, z) &= \exp(2x^2), \quad q_2(x, z) = (x - 0.5)^2 \\
q_3(x, z) &= \exp(2x^2)z^2, \quad q_4(x, z) = \sin(2\pi(x + z)) \\
\end{align*}
\]

and

\[
\begin{align*}
s_1(x, z) &= 0.5(x + 0.2), \quad s_2(x, z) = 0.5(\sin(x) + 1.2) \\
s_3(x, z) &= 0.5(z + 0.2), \quad s_4(x, z) = 0.5\sqrt{(x + 0.2)(z + 0.2)}. \\
\end{align*}
\]

The random variables \( X \) and \( Z \) are independent and uniformly distributed on the interval \([0, 1]\) while \( \epsilon \) is standard normal. We consider the cases \( \tau = 0.5 \) and \( \tau = 0.25 \). All reported results are based on 1000 simulation runs with 300 bootstrap replications.

The bootstrap test (at level \( \alpha \)) rejects the null hypothesis that the variable \( Z \) is not significant, whenever

\[
\tilde{K}_n > K_{n,1-\alpha}^* \quad (4.7)
\]

where \( \tilde{K}_n \) is defined in (4.3) and \( K_{n,1-\alpha}^* \) denotes the \((1 - \alpha)\) bootstrap quantile of the Kolmogorov-Smirnov test statistic.

The rejection probabilities of this test under the null hypothesis are shown in Table 1 for the 50% and 25% quantile. Note that different pairs of location and scale functions in (4.5) and (4.6) correspond to the null hypothesis for \( \tau = 0.5 \) and \( \tau = 0.25 \) (more precisely the models defined by the pairs \((1, 3), (1, 4), (2, 3)\) and \((2, 4)\) correspond to the null hypothesis if \( \tau = 0.5 \) but to the alternative if \( \tau = 0.25 \)). We observe from Table 1 that the level is usually approximated very well. For \( \tau = 0.25 \) there exist some cases where the test is slightly conservative.
Significance testing in quantile regression

Table 1
Simulated rejection probabilities of the bootstrap test (4.7) for significance of the variable $Z$ in the quantile regression model (4.4) for $\tau = 0.5$ (upper part) and $\tau = 0.25$ (lower part) under various null hypotheses. The pair $(j, k)$ corresponds to the location function $q_j$ and scale function $s_k$ specified in (4.5) and (4.6), respectively.

| $\tau$ | $(j, k)$ | $\alpha = 0.025$ | $\alpha = 0.05$ | $\alpha = 0.1$ |
|--------|----------|------------------|------------------|-----------------|
|        |          | $n = 50$ | $n = 100$ | $n = 50$ | $n = 100$ | $n = 50$ | $n = 100$ |
| 0.5    | (1,1)    | 0.037  | 0.035  | 0.053  | 0.061  | 0.102  | 0.111  |
|        | (1,2)    | 0.026  | 0.025  | 0.044  | 0.048  | 0.090  | 0.101  |
|        | (1,3)    | 0.041  | 0.027  | 0.069  | 0.066  | 0.132  | 0.127  |
|        | (1,4)    | 0.040  | 0.033  | 0.060  | 0.059  | 0.120  | 0.121  |
|        | (2,1)    | 0.036  | 0.031  | 0.068  | 0.057  | 0.122  | 0.106  |
|        | (2,2)    | 0.024  | 0.028  | 0.051  | 0.046  | 0.092  | 0.085  |
|        | (2,3)    | 0.037  | 0.025  | 0.057  | 0.059  | 0.132  | 0.114  |
|        | (2,4)    | 0.027  | 0.024  | 0.050  | 0.047  | 0.109  | 0.093  |
| 0.25   | (1,1)    | 0.024  | 0.019  | 0.044  | 0.035  | 0.089  | 0.082  |
|        | (1,2)    | 0.024  | 0.019  | 0.044  | 0.037  | 0.089  | 0.092  |
|        | (2,1)    | 0.027  | 0.025  | 0.047  | 0.052  | 0.102  | 0.105  |
|        | (2,2)    | 0.016  | 0.022  | 0.036  | 0.048  | 0.089  | 0.101  |

The corresponding results for various alternatives are displayed in Table 2 and we observe a reasonable power for most cases. The power for $\tau = 0.25$ is always smaller than the power for $\tau = 0.5$. This corresponds to intuition because the 25%-quantile is more difficult to estimate than the median. The power of the test is smaller for alternatives corresponding to the location function $q_4(x, z) = \sin(2\pi(x + z))$ if the sample size is $n = 100$. However, if the sample size is larger,

Table 2
Simulated rejection probabilities of the bootstrap test (4.7) for significance of the variable $Z$ in the quantile regression model (4.4) for $\tau = 0.5$ (upper part) and $\tau = 0.25$ (lower part) under various alternatives. The pair $(j, k)$ corresponds to the location function $q_j$ and scale function $s_k$ specified in (4.5) and (4.6), respectively.

| $\tau$ | $(j, k)$ | $\alpha = 0.025$ | $\alpha = 0.05$ | $\alpha = 0.1$ |
|--------|----------|------------------|------------------|-----------------|
|        |          | $n = 50$ | $n = 100$ | $n = 50$ | $n = 100$ | $n = 50$ | $n = 100$ |
| 0.5    | (3,1)    | 0.999  | 1.000  | 1.000  | 1.000  | 1.000  | 1.000  |
|        | (3,2)    | 0.975  | 0.983  | 0.815  | 0.989  | 0.886  | 0.997  |
|        | (3,3)    | 0.997  | 1.000  | 0.999  | 1.000  | 0.999  | 1.000  |

|        | (4,1)    | 0.082  | 0.197  | 0.142  | 0.311  | 0.252  | 0.519  |
|        | (4,2)    | 0.034  | 0.070  | 0.067  | 0.119  | 0.138  | 0.237  |
|        | (4,3)    | 0.089  | 0.176  | 0.134  | 0.279  | 0.226  | 0.488  |
|        | (4,4)    | 0.070  | 0.203  | 0.123  | 0.321  | 0.218  | 0.508  |
| 0.25   | (3,1)    | 0.999  | 0.240  | 0.163  | 0.325  | 0.245  | 0.459  |
|        | (3,2)    | 0.944  | 0.078  | 0.086  | 0.133  | 0.155  | 0.225  |
|        | (3,3)    | 0.139  | 0.295  | 0.204  | 0.405  | 0.332  | 0.540  |
|        | (3,4)    | 0.036  | 0.089  | 0.106  | 0.152  | 0.176  | 0.232  |
|        | (4,1)    | 0.935  | 1.000  | 0.971  | 1.000  | 0.988  | 1.000  |
|        | (4,2)    | 0.464  | 0.857  | 0.591  | 0.913  | 0.725  | 0.954  |
|        | (4,3)    | 0.792  | 0.990  | 0.873  | 0.996  | 0.934  | 0.999  |
|        | (4,4)    | 0.900  | 1.000  | 0.948  | 1.000  | 0.975  | 1.000  |
|        | (4,1)    | 0.027  | 0.054  | 0.055  | 0.103  | 0.111  | 0.229  |
|        | (4,2)    | 0.019  | 0.031  | 0.034  | 0.061  | 0.078  | 0.132  |
|        | (4,3)    | 0.022  | 0.051  | 0.043  | 0.091  | 0.104  | 0.176  |
|        | (4,4)    | 0.021  | 0.054  | 0.053  | 0.093  | 0.104  | 0.195  |
the test also detects the alternatives with reasonable probability. For example if $n = 200$ and $\tau = 0.5$ the simulated rejection probabilities of the bootstrap test at level 5% for the alternatives (4, 2), (4, 3) and (4, 4) are given by 0.319, 0.795 and 0.821, respectively.

Next we study the impact of the choice of the bandwidth on size and power of the bootstrap test. For this purpose we consider the sample size $n = 50$ and bandwidths 0.05, 0.10, 0.15, 0.20, 0.25, 0.30, 0.35, 0.40, 0.45 and 0.50. The results for model (1, 2) and (3, 2) corresponding to the null hypothesis and alternative, respectively, are summarized in Table 3. We observe that the level and power are rather stable with respect to different choices of the bandwidth. Simulations for other scenarios yield similar results and are not shown for the sake of brevity.

We also present a numerical study with a brief investigation of a two dimensional predictor, say $Z = (Z_1, Z_2)$. Because the method proposed in this paper does not require smoothing in the $Z$-direction, the results should not be seriously affected, if the dimension of $Z$ is larger. To be precise we consider two different location functions

$$q_1(x, z_1, z_2) = x, \quad q_2(x, z_1, z_2) = z_2 \cdot x + z_1^2$$ (4.8)

and a constant scale function $s(x, z_1, z_2) = 0.5$ in model (4.4). Note that $q_1$ corresponds to the null hypothesis, while $q_2$ represents an alternative. The results of the bootstrap test for the median are listed in Table 4 for the sample size $n = 50$ and we observe in these examples similar satisfactory properties as in the one-dimensional setting.

Instead of using the bootstrap test statistic $T_n^*(\Theta, z)$ defined in (4.1) one could think about using a similar version with $\tau$ instead of $\hat{\tau}$, that is

$$\tilde{T}_n^*(\Theta, z) = \frac{1}{n} \sum_{i=1}^{n} (\tilde{B}_i - \tau) I\{X_i \in \Theta\} \left( I\{Z_i \leq z\} - \hat{F}_{Z|X,\varepsilon}(z|X_i, 0) \right)$$ (4.9)

with $\tilde{B}_i = I\{U_i \leq \tau\}, i = 1, \ldots, n$. It turned out in our simulation study, that in many cases, especially for the median, the results are nearly the same.

### Table 3

| $\tau$ | $h$ | 0.05 | 0.10 | 0.15 | 0.20 | 0.25 | 0.30 | 0.35 | 0.40 | 0.45 | 0.50 |
|--------|-----|------|------|------|------|------|------|------|------|------|------|
| 0.5    | (1,2) | 0.037 | 0.036 | 0.037 | 0.037 | 0.047 | 0.054 | 0.061 | 0.061 | 0.047 | 0.044 |
|        | (3,2) | 0.565 | 0.724 | 0.774 | 0.793 | 0.821 | 0.825 | 0.802 | 0.855 | 0.837 | 0.837 |
| 0.25   | (1,2) | 0.017 | 0.031 | 0.037 | 0.033 | 0.031 | 0.048 | 0.042 | 0.049 | 0.041 | 0.063 |
|        | (3,2) | 0.164 | 0.362 | 0.435 | 0.485 | 0.516 | 0.528 | 0.571 | 0.567 | 0.571 | 0.571 |

### Table 4

| $\alpha$ | 0.025 | 0.050 | 0.100 |
|----------|-------|-------|-------|
| $q_1$    | 0.026 | 0.042 | 0.096 |
| $q_2$    | 0.998 | 1.000 | 1.000 |
Significance testing in quantile regression

Table 5
Simulated rejection probabilities of the bootstrap test based on $\tilde{T}_n^*(\Theta, z)$ defined in (4.9) for significance of the variable $Z$ with $n = 50$ in the quantile regression model (4.4) for $\tau = 0.5$ (upper part) and $\tau = 0.25$ (lower part) under various null hypotheses. The pair $(j, k)$ corresponds to the location function $q_j$ and scale function $s_k$ specified in (4.5) and (4.6), respectively.

| $\tau$ | $(j, k)$ | $\alpha = 0.025$ | $\alpha = 0.05$ | $\alpha = 0.1$ |
|--------|----------|------------------|------------------|------------------|
| 0.5    | (1,1)    | 0.020            | 0.037            | 0.071            |
|        | (1,2)    | 0.019            | 0.036            | 0.079            |
|        | (1,3)    | 0.020            | 0.036            | 0.089            |
|        | (1,4)    | 0.010            | 0.023            | 0.043            |
|        | (2,1)    | 0.043            | 0.069            | 0.125            |
|        | (2,2)    | 0.032            | 0.067            | 0.124            |
|        | (2,3)    | 0.042            | 0.079            | 0.134            |
|        | (2,4)    | 0.042            | 0.076            | 0.125            |
| 0.25   | (1,1)    | 0.015            | 0.028            | 0.057            |
|        | (1,2)    | 0.023            | 0.035            | 0.081            |
|        | (2,1)    | 0.014            | 0.032            | 0.069            |
|        | (2,2)    | 0.025            | 0.041            | 0.082            |

Table 6
Simulated rejection probabilities of the bootstrap test based on $\hat{T}_n^*(\Theta, z)$ defined in (4.9) for significance of the variable $Z$ with $n = 50$ in the quantile regression model (4.4) for $\tau = 0.5$ (upper part) and $\tau = 0.25$ (lower part) under various alternatives. The pair $(j, k)$ corresponds to the location function $q_j$ and scale function $s_k$ specified in (4.5) and (4.6), respectively.

| $\tau$ | $(j, k)$ | $\alpha = 0.025$ | $\alpha = 0.05$ | $\alpha = 0.1$ |
|--------|----------|------------------|------------------|------------------|
| 0.5    | (3,1)    | 1                | 1                | 1                |
|        | (3,2)    | 1                | 1                | 1                |
|        | (3,3)    | 1                | 1                | 1                |
|        | (3,4)    | 1                | 1                | 1                |
|        | (4,1)    | 0.094            | 0.164            | 0.278            |
|        | (4,2)    | 0.087            | 0.148            | 0.249            |
|        | (4,3)    | 0.086            | 0.141            | 0.249            |
|        | (4,4)    | 0.110            | 0.172            | 0.306            |
| 0.25   | (1,3)    | 0.065            | 0.117            | 0.182            |
|        | (1,4)    | 0.028            | 0.057            | 0.098            |
|        | (2,3)    | 0.118            | 0.181            | 0.270            |
|        | (2,4)    | 0.045            | 0.075            | 0.146            |
|        | (3,1)    | 0.924            | 0.966            | 0.988            |
|        | (3,2)    | 0.404            | 0.541            | 0.697            |
|        | (3,3)    | 0.742            | 0.833            | 0.917            |
|        | (3,4)    | 0.891            | 0.943            | 0.983            |
|        | (4,1)    | 0.015            | 0.029            | 0.089            |
|        | (4,2)    | 0.024            | 0.041            | 0.083            |
|        | (4,3)    | 0.018            | 0.041            | 0.090            |
|        | (4,4)    | 0.016            | 0.036            | 0.088            |

However, there are several situations where the use of $\hat{\tau}$ instead of $\tau$ yields better results. In particular this is the case for the 0.25 quantile where the test based on $\hat{T}_n^*(\Theta, z)$ is more conservative than the one based on $T_n^*(\Theta, z)$ (see Tables 5 and 6, which show the rejection probabilities of the bootstrap test based on the process (4.9) for the sample size $n = 50$ in the scenarios considered in Table 1 and 2). Moreover, the choice of the bandwidth has a smaller impact on the bootstrap test based on $T_n^*(\Theta, z)$ than on the test based on $\hat{T}_n^*(\Theta, z)$. 
Simulated rejection probabilities of the bootstrap test based on $\tilde{T}_n^*(\Theta, z)$ defined in (4.9) for various bandwidths. The sample size is $n = 50$ and the lower and upper part correspond to the 50% and 25% quantile, respectively. The pair $(j, k)$ corresponds to the location function $q_j$ and scale function $s_k$ specified in (4.5) and (4.6), respectively.

| $\tau$ | $h$ | 0.05 | 0.10 | 0.15 | 0.20 | 0.25 | 0.30 | 0.35 | 0.40 | 0.45 | 0.50 |
|--------|----|------|------|------|------|------|------|------|------|------|------|
| 0.5    | (1,2) | 0.018 | 0.034 | 0.037 | 0.04 | 0.046 | 0.044 | 0.062 | 0.06 | 0.045 | 0.048 |
|        | (3,2) | 0.583 | 0.723 | 0.764 | 0.75 | 0.823 | 0.797 | 0.817 | 0.83 | 0.822 | 0.823 |
| 0.25   | (1,2) | 0.008 | 0.02 | 0.022 | 0.031 | 0.038 | 0.045 | 0.04 | 0.042 | 0.037 |
|        | (3,2) | 0.08 | 0.32 | 0.387 | 0.451 | 0.522 | 0.533 | 0.521 | 0.57 | 0.55 | 0.578 |

This is clearly visible from a comparison of Table 3 with Table 7, which shows the impact of the choice of the bandwidth on the bootstrap test based on the statistic $\tilde{T}_n^*(\Theta, z)$ defined in (4.9). In our experience, both using $\hat{\tau}$ instead of $\tau$ and considering $\hat{F}_Z$ in $\tilde{T}_n$ has a stabilizing effect on the test statistic when the sample size is small.

5. Some concluding remarks

The results presented in this paper have several important extensions, which open interesting directions for future research. First, as pointed out by the referee and the Associate Editor, one might replace the indicators $I\{X_i \leq x\}$ by a collection of more general functions $g(X_i)$ where the functions $g$ range over some class, say $\mathcal{G}$. If for a given class of functions $\mathcal{G}$ the assumption

$$0 = \sup_{g \in \mathcal{G}} \sup_z \left| E \left[ (I\{Y_i \leq q_\tau(X_i)\} - \tau)g(X_i)I\{Z_i \leq z\} \right] \right|$$

is equivalent to

$$P(Y \leq q_\tau(X) \mid X, Z) = \tau \ \text{a.s.}$$

one would obtain a consistent test of the null hypothesis $H_0$ in (2.1). Under suitable technical assumptions, results on the asymptotic distribution of the test statistic similar to the ones provided in Section 3 can be derived. Moreover, one would expect that the choice of the class $\mathcal{G}$ would influence the power properties of the test. However, quantifying such an influence in a general setting seems to be very challenging, since it will require results on the behavior of quantiles of suprema of general Gaussian processes indexed by classes of functions.

Secondly, in some cases it is also of interest to investigate if the predictor $Z$ is irrelevant for all quantiles that is

$$E[I\{Y \leq q_\tau(X)\} - \tau \mid X, Z] = P(Y \leq q_\tau(X) \mid X, Z) - \tau = 0 \ \text{for all} \ \tau \in (0, 1).$$

This corresponds to the hypothesis of conditional independence and a test statistic can easily be obtained from the stochastic process $\{L_n(\tau, x, z) \mid \tau \in (0, 1), x \in R_X, z \in R_Z\}$, where

$$L_n(\tau, x, z) = \frac{1}{n} \sum_{i=1}^n (I\{Y_i \leq \hat{q}_\tau(X_i)\} - \tau)I\{X_i \leq x\}I\{Z_i \leq z\},$$

(4.10)
In order to study properties of a corresponding test such as sup, sup_x |L_n(τ, x, z)| one has to prove weak convergence of the process (4.10). We expect that this is possible under suitable assumptions. However, a rigorous proof requires additional technical work which will be beyond the scope of the present paper and therefore deferred to future research.

Acknowledgements

The authors thank Martina Stein, who typed parts of this manuscript with considerable technical expertise. This work has been supported in part by the Collaborative Research Center “Statistical modeling of nonlinear dynamic processes” (SFB 823, Teilprojekt C1, C4) of the German Research Foundation (DFG). We would also thank the referee and the associate editor for their constructive comments on the first version of this paper.

Appendix A: Appendix: Proofs

Throughout this section, introduce the abbreviation Θ_n := Θ ∩ D_n with D_n := \{x : [x - h_n, x + h_n] ⊂ \mathbb{R} \}.  

Lemma A.1. If assumptions (K1)-(K6) and (A1)-(A3) are satisfied, then

\[
\hat{q}_r(x) = q_r(x) - \frac{1}{\hat{F}_X(0|x)} \int_{-1}^{1} \kappa(v) \Delta_S(q_{r+v\theta_n}(x)|x) dv + o_P(n^{-1/2}) \\
= : \hat{q}_{r,L}(x) + o_P(n^{-1/2})
\]

uniformly in x ∈ D_n where Δ_S(x|y) is defined in Lemma B.1 and has the property

\[
\sup_{v \in [-1,1]} |Δ_S(q_{r+v\theta_n}(x)|x)| = o_P \left( d_n + \left( \frac{\log n}{nh_n^d} \right)^{1/2} \right).
\]

Moreover, \( \hat{q}_{r,L}(x) \) is, with probability tending to one, \( d + 1 \) times continuously differentiable with derivatives bounded uniformly on \( D_n \).

Proof. Apply part (a) of Lemma B.4 to \( F_{Y|X}(\cdot|x) \) and part (c) of the same Lemma with \( F_1(\cdot|x) = F_{Y|X}(\cdot|x), F_2(\cdot|x) = \hat{F}_{Y|X}(\cdot|x; p) \). Combined the results with Lemma B.1 yields the assertion. \( \square \)

Lemma A.2. If assumptions (K1)-(K6), (A1)-(A4), (S1) and (S2) are satisfied, then

\[
\int \hat{F}_X(0|s)(\hat{q}_r(s) - q_r(s)) I\{s ∈ \Theta_n\} f_X(s) F_{Z|X}(z|s, 0) ds \\
= -\frac{1}{n} \sum_{i=1}^{n} \left( I\{\varepsilon_i ≤ 0\} - T \right) I\{X_i ∈ \Theta_n\} F_{Z|X}(z|X_i, 0) + o_P\left( \frac{1}{\sqrt{n}} \right)
\]

uniformly with respect to \( \Theta ∈ \Xi, z ∈ \mathbb{R}_Z \).
Proof. From Lemma A.1 we obtain the representation

\[
- \int f_{x|X}(0|s)(q_{r}(s) - q_{T}(s))I\{s \in \Theta_n\}f_{X}(s)F_{Z|X,x}(z|s,0)ds
\]

\[
= \int_{-1}^{1} \kappa(v) \int \Delta_{S}(q_{r+vb_n}(s)|s)I\{s \in \Theta_n\}f_{X}(s)F_{Z|X,x}(z|s,0)dsdv + o_P(n^{-1/2})
\]

\[
= \int_{-1}^{1} \kappa(v) \int \frac{1}{nh_n^d} \sum_{i} \mathbf{M}(s) \left( \Omega \left( \frac{q_{r+vb_n}(s) - Y_i}{d_n} \right) - F_{Y|X}(q_{r+vb_n}(s)|X_i) \right)
\]

\[
\times \left( \mathbf{K}_{h_n,0}(s - X_i), \ldots, \mathbf{K}_{h_n,k_{N_p,p}}(s - X_i) \right)^t
\]

\[
\times I\{s \in \Theta_n\}(I_1(X_i; \Theta_n, h_n) + I_2(X_i; \Theta_n, h_n))f_{X}(s)F_{Z|X,x}(z|s,0)dsdv
\]

\[
+ o_P(n^{-1/2}),
\]

where

\[
\mathbf{M}(s) := e^{t} \left( \sum_{j=0}^{n_f} (-1)^j \left( \frac{\mathcal{M}(K)^{-1} f_X(x)}{f_X(x)} \right) \sum_{1 \leq |m| < n_f} h_n^{|m|} f_X^{(m)}(x) \mathcal{M}(K)^{-1} \right)
\]

and

\[
I_1(X; \Theta_n, h_n) := I\{i \in I : |X(j) - h_n, X(j) + h_n| \subset \Theta_n\},
\]

\[
I_2(X; \Theta_n, h_n) := I\{i \in I : |X(j) - h_n, X(j) + h_n| \not\subset \Theta_n, \}
\]

\[
\otimes_{j=1}^{d} [X(j) - h_n, X(j) + h_n] \cap \Theta_n \neq \emptyset\}.
\]

We will now proceed to show that the first part in the above decomposition \[i.e.\] the part containing \(I_1\) determines the asymptotic expansion and establish at the end of the proof that the part corresponding to \(I_2\) is asymptotically negligible.

First, note that

\[
\int \frac{1}{nh_n^d} \sum_{i} \mathbf{M}(s) \left( \Omega \left( \frac{q_{r+vb_n}(s) - Y_i}{d_n} \right) - F_{Y|X}(q_{r+vb_n}(s)|X_i) \right)
\]

\[
\times \left( \mathbf{K}_{h_n,0}(s - X_i), \ldots, \mathbf{K}_{h_n,k_{N_p,p}}(s - X_i) \right)^t
\]

\[
\times I\{s \in \Theta_n\}(I_1(X_i; \Theta_n, h_n) + I_2(X_i; \Theta_n, h_n))f_{X}(s)F_{Z|X,x}(z|s,0)ds
\]

\[
= \int_{[-1,1]^d} \frac{1}{n} \sum_{i} \mathbf{M}(X_i + h_n)s) \left( \Omega \left( \frac{q_{r+vb_n}(X_i + sh_n) - Y_i}{d_n} \right) - F_{Y|X}(q_{r+vb_n}(X_i + sh_n)|X_i) \right)
\]

\[
\times \left( \mathbf{K}_{1,0}(s), \ldots, \mathbf{K}_{1,k_{N_p,p}}(s) \right)^tI_1(X_i; \Theta_n, h_n)f_X(X_i + sh_n)
\]

\[
\times F_{Z|X,x}(z|X_i + sh_n,0)ds.
\]

Observe that every entry of \(\mathbf{M}\) is by assumption continuously differentiable with respect to \(s\) and the derivative is uniformly bounded. The class of functions
defined by
\[
\{(x, y) \mapsto \Omega\left(\frac{q_{\alpha}(x + a) - y}{d_n}\right)|\alpha(j)| \leq 1, j = 1, \ldots, d, |\zeta - \tau| \leq \alpha\}
\]
where \(\alpha\) is a small positive number that covers numbers that satisfy the assumptions of part 1 of Lemma B.3 in Appendix B. This follows from Lemma B.2 together with the fact that under the assumptions (A1), (A3) the mapping \((\zeta, a) \mapsto q_{\alpha}(x + a)\) satisfies
\[
\sup_x |q_{\alpha}(x + a_1) - q_{\alpha}(x + a_2)| \leq C(|\zeta_1 - \zeta_2| + \|a_1 - a_2\|_\infty)
\]
for some finite constant \(C\) (this inequality is a consequence of the implicit function theorem). Moreover, it follows from the smoothness assumptions on \(F_{Y|X}\) and the properties of \(\Omega\) that
\[
\sup_{|v| \leq 1, |t| \leq 1} \left| E\left[\Omega\left(\frac{q_{\tau + v h_n}(X_i + s h_n) - Y_i}{d_n}\right) - F_{Y|X}(q_{\tau + v h_n}(X_i + s h_n)|X_i)|X_i\right]\right| \leq R_n
\]
a.s., where \(R_n\) is a nonrandom quantity of order \(o(1/\sqrt{n})\). Thus the smoothness properties of \(F_{Z|X,z}, F_{Y|X}\) and \((\zeta, x) \mapsto q_{\alpha}(x)\) imply that by Lemma B.2 and Lemma B.3 in Appendix B we have
\[
\frac{1}{n} \sum_i M(X_i + h_n s) \left(\Omega\left(\frac{q_{\tau + v h_n}(X_i + s h_n) - Y_i}{d_n}\right) - F_{Y|X}(q_{\tau + v h_n}(X_i + s h_n)|X_i)})ight)
\]
\[
\times (K_{1,0}(s), \ldots, K_{1,k_{N,p},p}(s))^t I\{X_i \in \Theta_n, h_n\} f_X(X_i + s h_n)
\]
\[
\times F_{Z|X,z}(z|X_i + s h_n, 0)
\]
\[
= \frac{1}{n} \sum_i M(X_i) \left(K_{1,0}(s), \ldots, K_{1,k_{N,p},p}(s))^t I\{X_i \in \Theta_n\} f_X(X_i) F_{Z|X,z}(z|X_i, 0)
\]
\[
\times \left(\Omega\left(\frac{q_{\tau + v h_n}(X_i + s h_n) - Y_i}{d_n}\right) - F_{Y|X}(q_{\tau + v h_n}(X_i + s h_n)|X_i)\right)
\]
\[
+ o_P(n^{-1/2})
\]
uniformly with respect to \(|v| \leq 1, s \in [-1, 1]^d, \Theta \in \Xi\) and \(z \in R_Z\). Finally, noting that
\[
\Omega\left(\frac{q_{\tau + v h_n}(X_i + s h_n) - Y_i}{d_n}\right) = \Omega\left(\frac{q_{\tau + v h_n}(X_i + s h_n) - q_{\tau}(X_i) - \varepsilon_i}{d_n}\right)
\]
yields
\[
\sup_{v, s, t} \left|\Omega\left(\frac{q_{\tau + v h_n}(X_i + s h_n) - Y_i}{d_n}\right) - I(\varepsilon_i \leq 0)\right| \leq ||\Omega||_\infty I\{|\varepsilon_i| \leq R_n\} \quad \text{a.s.,}
\]
where $R_n = O(h_n + b_n + d_n)$ is a non-random quantity. This, together with an application of Lemma B.3, shows that

\[
\frac{1}{n} \sum_i M(X_i)(K_{1,0}(s), \ldots, K_{1,k_{N,p}}(s))^t I\{X_i \in \Theta_n\} f_X(X_i) F_{Z|X,e}(z|X_i, 0) 
\times \left( \Omega \left( q_{r+v_h}(X_i + sh_n) - Y_i \right) \right) 
= \frac{1}{n} \sum_i M(X_i)(I\{\varepsilon_i \leq 0\} - F_{\varepsilon|X}(0|X_i)) (K_{1,0}(s), \ldots, K_{1,k_{N,p}}(s))^t 
\times I\{X_i \in \Theta_n\} f_X(X_i) F_{Z|X,e}(z|X_i, 0) + o_P(n^{-1/2}).
\]

In particular, noting that $F_{\varepsilon|X}(0|X_i) = \tau$, the above result implies

\[
\int f_{\varepsilon|X}(0|s)(\tilde{q}_r(s) - q_r(s)) I\{s \in \Theta_n\} f_X(s) F_{Z|X,e}(z|s, 0) ds 
= \frac{1}{n} \sum_i M(X_i)(I\{\varepsilon_i \leq 0\} - \tau) (\mu_0(K), \ldots, \mu_{k_{N,p}}(K))^t I\{X_i \in \Theta_n\} 
\times f_X(X_i) F_{Z|X,e}(z|X_i, 0) + o_P(n^{-1/2}),
\]

where $\mu_K(K) := \int_{R^d} K_{1,k}(u) du$. Now from the definition of $M$ it is easy to see that

\[
M(x) = c_1^t (M_0(x)^{-1} + h_n R_M(x)) = c_1^t \left( \frac{M(K)^{-1}}{f_X(x)} + h_n R_M(x) \right)
\]

where $R_M$ denotes a vector whose entries are uniformly bounded and Lipschitz-continuous with respect to $x$. Thus applying Lemma B.3 we obtain

\[
\frac{1}{n} \sum_i M(X_i)(I\{\varepsilon_i \leq 0\} - \tau) (\mu_0(K), \ldots, \mu_{k_{N,p}}(K))^t I\{X_i \in \Theta_n\} 
\times f_X(X_i) F_{Z|X,e}(z|X_i, 0) 
= \frac{1}{n} \sum_{i=1}^n (I\{\varepsilon_i \leq 0\} - \tau) I\{X_i \in \Theta_n\} F_{Z|X,e}(z|X_i, 0) + o_P(n^{-1/2}),
\]

which completes the first part of the proof.

It remains to show that

\[
\frac{1}{n} \sum_i l_2(X_i; \Theta_n, h_n) \int_{-1}^1 \kappa(v) \int \frac{1}{h_n^s} M(s) \left( \Omega \left( \frac{q_{r+v_h}(s) - Y_i}{d_n} \right) \right) 
\times F_{Y|X}(q_{r+v_h}(s)|X_i) 
\times (K_{h_n,0}(s - X_i), \ldots, K_{h_n,k_{N,p}}(s - X_i))^t I\{s \in \Theta_n\} 
\times f_X(s) F_{Z|X,e}(z|s, 0) ds dv = o_P(n^{-1/2})
\]
uniformly with respect to $\Theta \in \Xi, z \in R^2$. To this end, consider the $(n$-dependent) class of functions $F_n$ with elements

$$f_{z, \Theta_n, h_n, b_n}(x, y) = \int_{-1}^{1} \frac{1}{h_n} M(s) \left( \Omega \left( \frac{q_{r+b_n}(s) - y}{d_n} \right) - F_{Y|X}(q_{r+b_n}(s)|x) \right) \times (K_{h_n, 0}(s - x), \ldots, K_{h_n, k_{N,p,p}}(s - x))^t I\{s \in \Theta_n\}$$

indexed by $z \in \mathcal{Z}, \Theta \in \Xi$ contains uniformly bounded elements (the bound is also uniform with respect to $n$). Moreover, there exists a finite positive constant $C$ such that

$$N_1(F_n, \varepsilon, L^2(P_X)) \leq \left( N_1(F_{n,1}, \varepsilon/C, L^2(P_X)) N_1(F_{n,2}, \varepsilon/C, L^2(P_X)) \right)^2,$$

where $F_{n,1} := \{s \mapsto I\{s \in \Theta_n\}|\Theta \in \Xi\}$ and $F_{n,2} := \{s \mapsto F_{Z|X,\varepsilon}(z|s, \varepsilon)|z \in \mathcal{Z}\}$. To see that this holds, observe the decomposition

$$f_{z, \Theta_n, h_n, b_n}(x, y) = f_{z, \Theta_n, h_n, b_n}^{(1)}(x, y) + f_{z, \Theta_n, h_n, b_n}^{(2)}(x, y)$$

$$:= \frac{1}{h_n} \sum_{j=1}^{2} \int \kappa(v) I\{|x - s| \leq h_n\} \int \chi_{\{s \in \Theta_n\}}(s, y, s, v) I\{s \in \Theta_n\}$$

where $g_{1,n}$ and $g_{2,n}$ denote non-positive and non-negative, uniformly bounded functions, respectively. Moreover, $g_{j,n}$ do not depend on $\Theta_n$ or $z$. Obviously, it suffices to bound the bracketing number of $F_{j,n} := \{s \mapsto f_{z, \Theta_n, h_n, b_n}^{(j)}(x, y)\}$ for $j = 1, 2$ separately. If we denote by $\{b_{L,j}, b_{U,j}\}$ a collection of $\varepsilon$--brackets (with respect to $L^2(P_X)$) for $\{s \mapsto F_{Z|X,\varepsilon}(z|s, \varepsilon)\}$. Then a collection of $\varepsilon/C$ brackets for $F_{n,2}$ (with respect to $L^2(P_X, Y)$) is given by

$$B_{K,j}(x, y) := \frac{1}{h_n} \int \kappa(v) I\{|x - s| \leq h_n\} \int \chi_{\{s \in \Theta_n\}}(s, y, s, v) b_{K,j}(s) ds dv,$$

where $K = U, L$. To see this, observe that

$$E[(B_{L,j}(X_1, Y_1) - B_{U,j}(X_1, Y_1))^2] \leq \int \int g_{2,n}(x, y, s, v) \frac{1}{h_n} \kappa(v) I\{|x - s| \leq h_n\} \chi_{\{s \in \Theta_n\}}(s, y, s, v) ds dv$$

$$\times \int \int \kappa(v) I\{|x - s| \leq h_n\} \chi_{\{s \in \Theta_n\}}(s, y, s, v) b_{U,j}(s) - b_{L,j}(s))^2 ds dv$$

$$\times \int \chi_{\{s \in \Theta_n\}}(x, y, s, v) ds dv$$

$$\leq C_1 \int \chi_{\{s \in \Theta_n\}}(x, y, s, v) ds dv$$

for some finite constant $C_1$. A bound for $F_{n,2}$ can be derived by similar arguments. Thus (A.1) is established. Combining the bound in (A.1) with the assumptions (S1) and (S2), the estimate $\sup_{z, \Theta_n} E[f_{z, \Theta_n, h_n, b_n}(X_1, Y_1)] = o(n^{-1/2})$, 
and the results from Lemma B.2 and Lemma B.3 yields the assertion after noting that by assumption \( \sup_{\theta \in \Xi} EL_2(X_i; \Theta_n, h_n) = o(1) \).

**Lemma A.3.** Under the assumptions of Theorem 3.2 it holds that

\[
T_n(\Theta_n, z) = \frac{1}{n} \sum_{i=1}^{n} (I(\xi_i \leq 0) - \tau) I\{X_i \in \Theta_n\} I\{Z_i \leq z\} + op(n^{-1/2})
\]

\[
+ \int (F_{\xi|X,Z}(\tilde{q}_{\tau, L}(s) - q_{\tau}(s), t) - F_{\xi|X,Z}(0, s, t)) \times
\]

\[
I\{s \in \Theta_n\} I\{t \leq z\} dF_{X,Z}(s, t),
\]

uniformly with respect to \( \Theta \in \Xi, z \in R_Z \), where \( F_{X,Z} \) denotes the joint distribution function of \( X, Z \).

**Proof.** Note that \( T_n(\Theta, z) = \frac{1}{n} \sum_{i=1}^{n} (I(\xi_i \leq 0) - \tau) I\{X_i \in \Theta\} I\{Z_i \leq z\} \), and that the assertion is equivalent to

\[
\sup_{\Theta \in \Xi, z \in Z} \left| \frac{1}{n} \sum_{i=1}^{n} (I(\hat{\xi}_i \leq 0) - I(\xi_i \leq 0)) I\{X_i \in \Theta\} I\{Z_i \leq z\} \right|
\]

\[
- E\left[ (I(\hat{\xi}_L \leq 0) - I(\xi \leq 0)) I\{X \in \Theta\} I\{Z \leq z\} \mid (Y_i, X_i, Z_i)_{i=1,\ldots,n} \right]
\]

\[
= op\left( \frac{1}{\sqrt{n}} \right).
\]

Here we define \( \hat{\xi}_i = Y_i - \hat{q}_{\tau}(X_i), \hat{\xi}_L = Y - \hat{q}_{\tau, L}(X) \), where we assume that the sample \( (Y_i, X_i, Z_i), i = 1, \ldots, n, \) is independent from the generic variable \( (Y, X, Z) \). The proof now proceeds in two steps. First, note that by Lemma A.1 we have \( \hat{q}_{\tau} - \hat{q}_{\tau, L} = o_P(n^{-1/2}) \) uniformly on \( D_n \) and thus there exists a deterministic sequence \( \gamma_n = o(n^{-1/2}) \) with

\[
P\left( \sup_{x \in D_n} |\hat{q}_{\tau}(x) - \hat{q}_{\tau, L}(x)| \leq \gamma_n \right) \to 1. \tag{A.2}
\]

Now on the set \( \{|\hat{q}_{\tau}(x) - \hat{q}_{\tau, L}(x)| \leq \gamma_n\} \), the probability of which tends to one, we have

\[
\sup_{\Theta \in \Xi, z \in Z} \left| \frac{1}{n} \sum_{i=1}^{n} (I(\hat{\xi}_i \leq 0) - I(\hat{\xi}_{i,L} \leq 0)) I\{X_i \in \Theta\} I\{Z_i \leq z\} \right|
\]

\[
\leq \frac{1}{n} \sum_{i=1}^{n} I\{|\hat{\xi}_{i,L} | \leq \gamma_n\} I\{X_i \in D_n\}.
\]

Next, note that \( I\{|\hat{\xi}_{i,L} | \leq \gamma_n\} = I\{|\xi_i - g(X_i)| \leq \gamma_n\} \) for \( g = \hat{q}_{\tau, L} - q_{\tau} \). Now the assertion follows since the \( (n\text{-independent}) \) class of functions

\[\{(\epsilon, \xi) \mapsto I\{|\epsilon - g(\xi)| \leq \gamma_n\} I\{\xi \in D_n\} \mid g \in C^{d+1}_{\text{in}}(R_X)\}\]

satisfies the assumptions of part 1 of Lemma B.3 whenever \( n \) is sufficiently large, see the proof of Lemma A.3 in Neumeyer and Van Keilegom (2010) for a similar
reasoning, and \( \hat{q}_r - q_r \in C_1^{d+1}(\mathcal{D}_n) \) with probability converging to one by Lemma A.1. Here \( C_1^{d+1}(\mathcal{D}_n) \) is the class of \( d+1 \) times differentiable functions \( g \) defined on \( \mathcal{D}_n \). Further, note that
\[
\sup_{g \in C_1^{d+1}(\mathcal{D}_n)} E \left[ I \{ |\varepsilon_i - g(X_i)| \leq \gamma_n \} I \{ X_i \in \mathcal{D}_n \} \right] = o(n^{-1/2}).
\]
This, together with (A.2), and an application of Lemma B.3, shows that
\[
\sup_{\Theta \in \Xi, z \in \mathbb{Z}} \left| \frac{1}{n} \sum_{i=1}^{n} (I \{ \hat{\varepsilon}_i \leq 0 \} - I \{ \varepsilon_i \leq 0 \}) I \{ X_i \in \Theta_n \} I \{ Z_i \leq z \} \right| = o_P(n^{-1/2}).
\]
Similar arguments applied to the \((n\text{-dependent})\) class functions
\[
\left\{ (\varepsilon, \xi, \zeta) \mapsto (I \{ \varepsilon \leq g(\xi) \} - I \{ \varepsilon \leq 0 \}) I \{ \xi \in \Theta_n \} I \{ \zeta \leq z \} \mid g \in C_1^{d+1}(R_X), \Theta \in \Xi, z \in \mathbb{Z} \right\}
\]
yield
\[
\sup_{\Theta \in \Xi, z \in \mathbb{Z}} \left| \frac{1}{n} \sum_{i=1}^{n} (I \{ \hat{\varepsilon}_i - \xi \leq 0 \} - I \{ \varepsilon_i \leq 0 \}) I \{ X_i \in \Theta_n \} I \{ Z_i \leq z \} \right|
\]
\[= -E \left[ (I \{ \hat{\varepsilon}_L \leq 0 \} - I \{ \varepsilon \leq 0 \}) I \{ X \in \Theta_n \} I \{ Z \leq z \} \mid (Y_i, X_i, Z_i), i = 1, \ldots, n \right] \]
\[= o_P(n^{-1/2}).\]
and thus the proof is complete. \( \square \)

\textbf{Proof of Theorem 3.2.} Starting from the stochastic expansion given in Lemma A.3 we obtain by Taylor’s expansion
\[
T_n(\Theta_n, z) = \frac{1}{n} \sum_{i=1}^{n} (I \{ \varepsilon_i \leq 0 \} - \tau) I \{ X_i \in \Theta_n \} I \{ Z_i \leq z \}
\]
\[+ \int f_{\varepsilon|X,Z}(0|s,t)(\hat{q}_r(s) - q_r(s)) I \{ s \in \Theta_n \} I \{ t \leq z \} dF_{X,Z}(s,t)
\]
\[+ \int f'_{\varepsilon|X,Z}(\xi, s, n|s,t)(\hat{q}_r(s) - q_r(s))^2 I \{ s \in \Theta_n \} I \{ t \leq z \} dF_{X,Z}(s,t)
\]
\[+ o_P(\frac{1}{\sqrt{n}})
\]
for some \( \xi, s, n \) between 0 and \( \hat{q}_r(s) - q_r(s) \) where the last line is of order \( o_P(n^{-1/2}) \) due to Lemma A.1 and the assumptions \( d_2^* + \log n / nh_1^d = o(n^{-1/2}) \), \( \sup_{x \in \mathcal{D}, y \in R, z \in R} |f'_{\varepsilon|X,Z}(y|x, z)|| < \infty \). Note that
\[
\int f_{\varepsilon|X,Z}(0|s,t)(\hat{q}_r(s) - q_r(s)) I \{ s \in \Theta_n \} I \{ t \leq z \} dF_{X,Z}(s,t)
\]
\[= \int F_{Z|X,z}(z|s, 0) f_{\varepsilon|X}(0|s) f_X(s)(\hat{q}_r(s) - q_r(s)) I \{ s \in \Theta_n \} ds.
\]
By Lemma A.2 we thus have

\[ T_n(\Theta_n, z) = \frac{1}{n} \sum_{i=1}^{n} (I(\xi_i \leq 0) - \tau) I\{X_i \in \Theta_n\} \left( I\{Z_i \leq z\} - F_{Z|X,z}(z|X_i,0) \right) \]

+ \text{op} \left( \frac{1}{\sqrt{n}} \right).

This completes the proof. \( \square \)

**Proof of Corollary 3.3 and 3.5.** Define the sequence of \( n \)-dependent classes of functions

\[ \mathcal{F}_n := \left\{ (e, \xi, \zeta) \mapsto e I\{\xi \in \Theta \cap D_n\} (I\{\zeta \leq z\} - F_{Z|X,z}(z|\xi,0)) \mid \Theta \in \Xi, z \in R_Z \right\} \]

and note that it is indexed by the totally bounded metric space \((\Xi \times R_Z, \rho)\) with metric

\[ \rho((\Theta_1, y), (\Theta_2, z)) := \left( E[(W_{\Theta_1,y} - W_{\Theta_2,z})^2] \right)^{1/2} \]

where \( W_{\Theta,z} := (I\{\zeta_1 \leq 0\} - \tau) I\{X_1 \in \Theta\} (I\{Z_1 \leq z\} - F_{Z|X,z}(z|X_1,0)) \).

Moreover, it satisfies the assumptions of part 2 of Lemma B.3. A simple calculation in combination with the assumption \( \sup_{\Theta \in \Xi} P(X_i \in \Theta \cap D_n) = o(1) \) shows that all the assumptions of Theorem 2.11.23 in van der Vaart and Wellner (1996) are satisfied. In particular, the covariances \( \text{Cov}(W_{\Theta_1,y}, W_{\Theta_2,z}) \) converge to \( k(\Theta, y, \Theta', z) \) given in Corollary 3.3. This implies that the process

\[ \sqrt{n} \left( T_n(\Theta_n, z) - \tilde{T}_n(\Theta_n, z) \right) = \frac{1}{n} \sum_{i=1}^{n} \left( (I(\xi_i \leq 0) - \tau) I\{X_i \in \Theta_n\} (I\{Z_i \leq z\} - F_{Z|X,z}(z|X_i,0)) - \tilde{T}_n(\Theta_n, z) \right) \]

+ \text{op} \left( \frac{1}{\sqrt{n}} \right),

where \( \tilde{T}_n(\Theta_n, z) := E \left[ (I(\xi_i \leq 0) - \tau) I\{X_i \in \Theta_n\} (I\{Z_i \leq z\} - F_{Z|X,z}(z|X_i,0)) \right] \) converges weakly to the centered Gaussian process \( T(\Theta, z) \) described in Corollary 3.3. Thus Corollary 3.3 and 3.5 follow after a straightforward calculation of the expectation \( \tilde{T}_n(\Theta_n, z) \). Now the proof is complete. \( \square \)

**Appendix B: Technical results**

Before stating the main results of this section, we discuss some basic properties of the local polynomial estimator \( \hat{F}_{Y|X}(y|x;p) \). To this end, we note that

\[ \mathbf{X}' \mathbf{WY} = (V_{n,0}(x,y), V_{n,k_1}(x,y), \ldots, V_{n,k}\mathbb{K}_p(x,y))' \]

with

\[ V_{n,k}(x,y) := \frac{h_k^{|n|}}{nh_k^d} \sum_{i=1}^{n} K_{h_k,k}(x-X_i) \Omega \left( \frac{y-Y_i}{d_n} \right). \]
Lemma B.1. Under the assumptions (K1), (K2), (K5), (A1), (A2) it holds that

$$
\hat{F}_{Y|X}(y|x;p) - F_{Y|X}(y|x) = c_1 \left( \sum_{j=0}^{n_f} \left( - \frac{M(K)^{-1}}{f_X(x)} \sum_{1 \leq |m| < n_f} h_n^{|m|} f_X^{|m|}(x) M_m \right)^j \frac{M(K)^{-1}}{f_X(x)} \right) \\
\times (T_{n,0,S}(x,y), \ldots, T_{n,k_{N_p,p,S}}(x,y))^T + O_P(n^{-1/2}) \\
= \Delta_S(y|x) + O_P(n^{-1/2}) = O_P(d_n^* + \left( \frac{\log n}{nh_n^d} \right)^{1/2})
$$

uniformly with respect to $(x,y) \in \mathcal{D}_n \times \mathcal{Y}$, where $\mathcal{Y}$ is any bounded subset of $\mathbb{R}$ and $M_k$ denote some matrices with uniformly bounded entries that are independent of $n, x, y$ and

$$
T_{n,k,S}(x,y) := \frac{1}{nh_n^d} \sum_i K_{h_n,k}(x - X_i) \left( \Omega \left( \frac{y - Y_i}{d_n} \right) - F_{Y|X}(y|X_i) \right).
$$

Moreover, the quantity $\Delta_S(y|x)$ is, with probability tending to one, $d + 1$ times continuously differentiable with respect to $x$ and $y$ and all its partial derivatives of corresponding orders are uniformly bounded on $\mathcal{D}_n \times \mathcal{Y}$.

Proof. At the end of the proof, we will establish the following two representations

$$
\hat{F}_{Y|X}(y|x;p) = F_{Y|X}(y|x) + c_1 (X^T W X)^{-1} (h_n^0 T_{n,0,S}(x,y), \ldots, h_n^p T_{n,k_{N_p,p,S}}(x,y))^T + O_P(h_n^{p+1}), \quad (B.1)
$$

$$
(X^T W X)^{-1} = H^{-1} \left( \sum_{j=0}^{n_f} \left( - \frac{M(K)^{-1}}{f_X(x)} \sum_{1 \leq |m| < n_f} h_n^{|m|} M_m f_X^{|m|}(x) \right)^j \frac{M(K)^{-1}}{f_X(x)} \right) + O_P(h_n^{n_f}) H^{-1}, \quad (B.2)
$$

where $M_0, \ldots, M_{k_{N_p,p,n_f}}$ denote some matrices that do not depend on $n, x, M_0 = M(K)$ is invertible, $H$ is a diagonal matrix with entries $1, h_n, h_n^2, \ldots, h_n^2, h_n^p, \ldots, h_n^p$ and the term $h_n^{|m|}$ appears $N_k$ times in this vector. By definition we have

$$
\partial_y \partial_x^m T_{n,k,S}(x,y) = \frac{1}{nh_n^{d+|m|}} \sum_i K_{h_n,k}(x - X_i) \left( \frac{1}{dh_n} \omega^{(r-1)} \left( \frac{y - Y_i}{d_n} \right) - F_{Y|X}(y|X_i) \right),
$$

and tedious but straightforward calculations including integration-by-parts and substitutions yield the estimates

$$
\sup_{(x,y) \in \mathcal{D}_n \times} E[|\partial_y \partial_x^m T_{n,k,S}(x,y)|] = O(d_n^{p-r}),
$$
\[
\sup_{(x,y) \in D_n} E[(\partial_y \partial_x^m T_{n,k,S}(x,y))^2] = O\left(\frac{1}{n h_n^{d+2|m|} d_n^{3/2(r-1)}}\right).
\]

A combination of parts 1, 2 and 6 of Lemma B.2 shows that, for every \(n\), the class of functions
\[
\mathcal{F}_n = \left\{(u,v) \mapsto K_{h_n,k}^{(m)}(x-u)\left(\frac{1}{d_n^r}\omega^{(r-1)}(y-u) - F_{Y|X}(y|u)\right) | x \in \mathbb{R}, y \in \mathbb{R}\right\}
\]
satisfies the assumptions of part 2 of Lemma B.3 with constants not depending on \(n\), which, together with the above estimates gives
\[
\sup_{(x,y) \in D} |\partial_y \partial_x^m T_{n,k,S}(x,y)| = O_P\left(\frac{\log n}{n h_n^{d+2|m|} d_n^{3/2(r-1)}}\right)^{1/2} + O(d_n^{-r}). \quad (B.3)
\]
Combining (B.1), (B.2) and (B.3) yields
\[
e^f_1(X^tWX)^{-1}(h_n^0 T_{n,0,S}(x,y), \ldots, h_n^p T_{n,k_{N,p},p,S}(x,y))^t = e^f_1 \left(\sum_{j=0}^{n} \left(\frac{M(K)^{-1}}{JX(x)} \sum_{1 \leq |l| < n} h_n^{|l|} M_l f_X^{(l)}(x)\right) j M(K)^{-1}\right)
\times (T_{n,0,S}(x,y), \ldots, T_{n,k_{N,p},p,S}(x,y))^t + o_P(n^{-1/2}),
\]
and thus the proof of the first part of the Lemma is complete.

For a proof of the differentiability results, note that the \(d+1\)-fold differentiability of the product of every entry of a scalar product between two vectors follows from the \(d+1\)-fold differentiability of every entry of both vectors. This establishes that \(\Delta_S(y|x)\) is \(d+1\) times continuously differentiable with respect to both components and that all partial derivatives are uniformly bounded. By the results in (B.3) the proof is thus complete once we establish (B.1) and (B.2).

**Proof of (B.1)** A Taylor expansion of \(F_{Y|X}(y|x)\) gives
\[
\frac{1}{n h_n^d} \sum_{i} K_{h_n,k}(x-X_i) F_{Y|X}(y|x)
\]
\[
= \frac{1}{n h_n^d} \sum_{0 \leq |m| \leq p} \partial_x^m F_{Y|X}(y|X_i) \frac{h_n^{|m|}}{m!} \sum_{i} K_{h_n,k+m}(x-X_i) + O_P(h_n^{m+|p+1|}).
\]
This fact, combined with
\[
e^f_1(X^tWX)^{-1} \left(\begin{array}{c}
h_n^{|m|} \sum_i K_{h_n,m}(x-X_i) \\
\vdots \\
h_n^{p+|m|} \sum_i K_{h_n,k_{N,p},m}(x-X_i)
\end{array}\right) = I\{m = 0\},
\]
yields the representation
\[
F_{Y|X}(y|x) = e^f_1(X^tWX)^{-1} \left(\begin{array}{c}
h_n^0 \sum_i K_{h_n,0}(x-X_i) F_{Y|X}(y|x) \\
\vdots \\
h_n^p \sum_i K_{h_n,k_{N,p}}(x-X_i) F_{Y|X}(y|x)
\end{array}\right)
\]
Thus we obtain a representation of the form

\[
\hat{F}_{Y|X}(y|x) = F_{Y|X}(y|x) + e_1^{(t)}(X'WX)^{-1}(h_0^0 T_{n,0,s}(x,y), \ldots, h_p^p T_{n,k_{N_{n,p}},s}(x,y))^t + O_P(h_n^{p+1}).
\]

**Proof of (B.2)** The elements of the matrix \(X'WX\) are of the form

\[
(X'WX)_{k,l} = \frac{1}{nh^d_n} \sum_i K_{h_n,0}(x - X_i)(x - X_i)^m = \frac{h_i^{|m|}}{nh^d_n} \sum_i K_{h_n,m}(x - X_i)
\]

where \(m = m_1 + m_2\) and \(m_1, m_2\) denote the \(k'\)th and \(l'\)th entry in the tuple of vectors \((0, k_1, \ldots, k_{N_n,1}, k_1, 2, \ldots, k_{N_n,p})\), respectively. In particular, \(d + 1 + n_f\)-fold continuous differentiability of \(f_X\) implies that

\[
\frac{1}{nh^d_n} \sum_i K_{h_n,k}(x - X_i) = \sum_{|i| < n_f} \mu_{|i|+|h|}(K) h_i^{(|i|)} f_X^{(i)}(x) + O_P\left(\frac{\log n}{nh^d_n}\right)^{1/2} + h_n^{n_f}.
\]

Thus we obtain a representation of the form

\[
X'WX = H \left( \sum_{|i| < n_f} h_i^{(|i|)} M_i f_X^{(i)}(x) + 1_{N \times N} O_P(h_n^{n_f}) \right) H
\]

where \(M_0, \ldots, M_{k_{N_{n,p}} - 1}\) denote some matrices that do not depend on \(n, x\), \(M_0 = M(K)\) is invertible and \(H\) is a diagonal matrix with entries \(1, h_n, \ldots, h_n, h_n^2, \ldots, h_n^2, \ldots, h_n^d\) where the term \(h_i^{(|i|)} \) appears \(N_k\) times in this vector [see the definition at the beginning of the section]. Thus for \(h_n\) sufficiently small an application of the Neumann series yields (B.2) with probability tending to one.

**Lemma B.2. Bounds on bracketing numbers**

1. Define \(\mathcal{F} + \mathcal{G} := \{f + g | f \in \mathcal{F}, g \in \mathcal{G}\}\), \(\mathcal{F} \mathcal{G} := \{fg | f \in \mathcal{F}, g \in \mathcal{G}\}\). Then

\[
N_{\|\|}(\mathcal{F} + \mathcal{G}, \varepsilon, \rho) \leq N_{\|\|}(\mathcal{F}, \varepsilon/2, \rho) N_{\|\|}(\mathcal{G}, \varepsilon/2, \rho).
\]

If additionally the classes \(\mathcal{F}, \mathcal{G}\) are uniformly bounded by the constant \(C\), we have

\[
N_{\|\|}(\mathcal{F} \mathcal{G}, \varepsilon, ||.||) \leq N_{\|\|}^2(\mathcal{F}, \varepsilon/4C, ||.||) N_{\|\|}^2(\mathcal{G}, \varepsilon/4C, ||.||)
\]

for any seminorm \(\|\|\) with the additional property that \(|f_2| \leq |f_2|\) implies \(\|f_1\| \leq \|f_2\|\).
2. Let $\mathcal{F}_n$ denote a class of functions $f_x$ indexed by the bounded interval $x \in [-A, A]$ which are bounded by a given constant and have support of the form $[x-h, x+h]$. If $\sup_{f \in \mathcal{F}} |f(a) - f(b)| \leq C|a-b|h^{-k}$ for some universal constant $C$ we have $N_1(\mathcal{F}_n, \varepsilon, L^2(P_X)) \leq C\gamma\varepsilon^{-(2k+1)}$ provided that $P_X$ has a uniformly bounded density. Here $\gamma$ denotes a constant which does not depend on $n$.

3. Consider the class of functions

$$\mathcal{F}_n := \{(x, y) \mapsto \Omega\left(\frac{g(x) - y}{d_n}\right) | g \in \mathcal{G}\},$$

where $\Omega$ is Lipschitz-continuous and there exist constants $C_1, C_2$ such that $\Omega$ is constant on $(-\infty, C_1]$ and $[C_2, \infty)$. Assume additionally that the distribution of $(X,Y)$ has a uniformly bounded density, then

$$N_1(\mathcal{F}_n, \varepsilon, L^2(P_{XY})) \leq C_5 N_1(\mathcal{G}, C_6\varepsilon^2, \| \cdot \|_{\infty})$$

for some constants $C_5, C_6$ independent of $n$.

4. For any measure $P^{U,V}$ on the unit interval with uniformly bounded density $f$, the class of functions

$$\mathcal{F} := \{u \mapsto I\{u \leq s\}|s \in [0,1]\} \cup \{u \mapsto I\{u < s\}|s \in [0,1]\}$$

can be covered by $C\varepsilon^{-2}$ brackets of $L^2(P)$ length $\varepsilon$.

5. For any measure $P$ on $\mathbb{R} \times \mathbb{R}^k$ with uniformly bounded conditional density $f_{V|U}$ the class of functions

$$\mathcal{G} := \{(u, v) \mapsto I\{v \leq f(u)\}|f \in \mathcal{F}\}$$

satisfies $N_1(\mathcal{G}, \varepsilon, \| \cdot \|_{P,2}) \leq N_1(\mathcal{F}, C\varepsilon^2, \| \cdot \|_{\infty})$ for some constant $C$ independent of $\varepsilon$.

6. Assume that $f(x;a)$ is a function indexed by the parameter $a \in A$ such that $\sup_x f(s,x) - f(t,x) \leq C|s-t|^{\theta}$ for some $\theta > 0$ and norm $\| \cdot \|$. Then the $\| \cdot \|_{\infty}$-bracketing numbers of the class of functions $\mathcal{F} = \{u \mapsto f(u|a), a \in A\}$ satisfy $N_1(\mathcal{F}, \varepsilon, \| \cdot \|_{\infty}) \leq C_1 N(A, C_2\varepsilon^{1/\theta}, \| \cdot \|)$ for some finite constants $C_1, C_2$.

**Proof.** Part 1 The first assertion is obvious from the definition of bracketing numbers. For the second assertion, note that $\mathcal{F}\mathcal{G} = (\mathcal{F} + C)(\mathcal{G} + C) - C\mathcal{F} - C\mathcal{G} + C^2$. Moreover, all elements of the classes $\mathcal{F} + C, \mathcal{G} + C$ are by construction non-negative and thus it also is possible to cover them with brackets consisting of non-negative functions and amounts equal to the brackets of $\mathcal{F}, \mathcal{G}$, respectively. Finally, observe that if $0 \leq f_t \leq f \leq f_u$ and $0 \leq g_t \leq g \leq g_u$, we also have $f_t g_t \leq f \leq f_u g_u$. Moreover $\|f_t g_t - f_u g_u\| \leq C\|f_u - f_t\| + C\|g_u - g_t\|$. Thus the class $(\mathcal{F} + C)(\mathcal{G} + C)$ can be covered by at most $\leq N_1(\mathcal{F}, \varepsilon, \| \cdot \|)N_1(\mathcal{G}, \varepsilon, \| \cdot \|)$ brackets of length $2C\varepsilon$. Finding brackets for the classes $C\mathcal{F}, C\mathcal{G}$ is trivial, and applying the first assertion of the Lemma completes the proof.
Consider two cases.

A) \( \varepsilon > 4h^{1/2} \): Divide \([0, 1]\) into \( N := 2/\varepsilon^2 \) subintervals of length \( 2\alpha := \varepsilon^2 \) with centers \( \alpha r \) for \( r = 1, \ldots, N \) and call the intervals \( I_1, \ldots, I_N \). Note that two adjacent intervals overlap by \( \alpha > 2h \). This construction ensures that every set of the form \([x - h, x + h]\) with \( x \in [h, 1 - h] \) is completely contained in at least one of the intervals defined above. Then a collection of \( N \) brackets of \( L^2 \)-length \( D \varepsilon \) for some \( D > 0 \) independent of \( h \) is given by \( (-C I \{ u \in I_j \}, C I \{ u \in I_j \}) \).

B) \( \varepsilon \leq 4h^{1/2} \): Observe that by assumption any element \( g \) of \( F \) satisfies \( |g(x) - g(y)| \leq C |x - y| h^{-k} \). Consider the points \( t_i := i/(N + 1), i = 1, \ldots, N \) with \( N := 2^{2k+1}C/\varepsilon^{2k+1} \). By construction, to every \( x \in [h, 1 - h] \) there exists \( i(x) \) with \( |t_i(x) - x| \leq \varepsilon^{2k+1}/(2^{2k+1}C) \). This implies

\[
|g(x) - g(t_i(x))| \leq C \varepsilon^{2k+1}h^{-k}/2^{2k+1}C \leq \varepsilon/2
\]

Then \( N \| . \|_\infty \)-brackets of length covering \( F \) are given by \( (g(t_i) - \varepsilon/2, g(t_i) + \varepsilon/2), i = 1, \ldots, N \). From those one can easily construct \( L^2(P_X) \)-brackets.

**Part 3** Without loss of generality, assume that \( \Omega \) equals one on \([1, \infty)\) and zero on \((-\infty, -1]\). Moreover, the assumptions on \( \Omega \) imply the existence of finite constant \( C_1, C_u \) such that \( C_1 \leq \Omega \leq C_u \). Distinguish two cases

A) \( \varepsilon \leq d_n \): Starting with \( \varepsilon^2 \) supremum norm brackets for the class \( G \) and using the Lipschitz condition yields the desired brackets.

B) \( \varepsilon > d_n \): Denote by \([g_1, t, g_1, u], \ldots, [g_{N(y), t, g_{N(y)}, u}]\) brackets for the class \( G \) of \( \| . \|_\infty \)-size \( \varepsilon \). For a function \( g \in G \), denote the bracket that contains it by \([g_j, t, g_j, u]\). Observe that

\[
\Omega \left( \frac{g(x) - y}{d_n} \right) = \begin{cases} 
0, & \text{if } y > g_j, u(x) + d_n \\
1, & \text{if } y < g_j, l(x) - d_n \\
\in [C_l, C_u], & \text{else}
\end{cases}
\]

Thus brackets of the form

\[
b_{l,j}(x) := I \{ y < g_{j, l}(x) - d_n \} + C_l I \{ g_{j, l}(x) - d_n \leq y \leq g_{j, u}(x) + d_n \}
\]

\[
b_{u,j}(x) := I \{ y < g_{j, l}(x) - d_n \} + C_u I \{ g_{j, l}(x) - d_n \leq y \leq g_{j, u}(x) + d_n \}
\]

contain every function in \( F_n \). Moreover, the \( L^2 \)-length of each such bracket is bounded by \( (C_u - C_l)(2d_n + \varepsilon) \sup_{X, Y} f_{X, Y}(x, y) \leq C \varepsilon \). This completes the proof.

**Part 4** Follows by standard arguments.

**Part 5** Follows from \(|I \{ v \leq g_1(u) \} - I \{ v \leq g_2(u) \}| \leq I \{ |v - g_1(u)| \leq 2 \| g_2 - g_2 \|_\infty \} \).

**Part 6** Obvious.

**Lemma B.3** (Basic Lemma). Assume that the classes of functions \( F_n \) consist of uniformly bounded functions (by a constant not depending on \( n \)).

1. If for some \( a < 2 \), \( N_1(F_n, \varepsilon, L^2(P)) \leq C \exp(-\varepsilon^{-a}) \) for every \( \varepsilon \leq \delta_n \) with constants \( C, c \) not depending on \( n \), then we have

\[
\sqrt{n} \sup_{f \in F_n, \| f \|_{\varepsilon, 2} \leq \delta_n} \left( \int f dP_n - \int f dP \right) = o_p^*(1),
\]
for \( \delta_n \searrow 0 \), where the \( * \) denotes outer probability, see van der Vaart and Wellner (1996) for a more detailed discussion.

2. If \( N_{\|}((F_n, \varepsilon, L^2(P)) \leq C \varepsilon^{-a} \) for every \( \varepsilon \leq \delta_n \), some \( a > 0 \) and a constant \( C \) not depending on \( n \), then we have for any \( \delta_n \sim n^{-b} \) with \( b < 1/2 \)

\[
\sqrt{n} \sup_{f \in \mathcal{F}_n, \|f\|^2_{\mathcal{F}_2} \leq \delta_n} \left( \int f dP_n - \int f dP \right) = O_P \left( \delta_n \log \delta_n \right).
\]

**Proof.** Start by observing that the uniform boundedness of elements of \( \mathcal{F}_n \) by \( D \) implies that \( F \equiv D \) is a measurable envelope function with \( L^2 \)-norm \( D \). The proof of the first part follows by arguments similar to those used for the proof of the second part and is therefore omitted. For the proof of the second part, note that for \( \eta_n \) sufficiently small

\[
a(\eta_n) := \eta_n D / \sqrt{1 + \log N_{\|}(\eta_n D, \mathcal{F}_n, L^2(P))} \geq D \eta_n / \sqrt{1 + \log C - a \log(D \eta_n)}
\]

for some finite constant \( \tilde{C} \) depending only on \( a, C, D \). Thus the bound in Theorem 2.14.2 in van der Vaart, Wellner (1996) yields for \( \delta_n \) sufficiently small

\[
\begin{align*}
E \left[ \sup_{f \in \mathcal{F}_n} \int f \, d\alpha_n \right]^* & \leq DJ_{\|}(\delta_n, \mathcal{F}_n, L^2(P)) + \sqrt{n} \int F(u) I\{F(u) > \sqrt{n} a(\delta_n)\} P(du) \\
& \leq DC_1 \int_0^{\delta_n} \log \varepsilon |d\varepsilon| + D \sqrt{n} I\{D > \tilde{C} \sqrt{n} \delta_n \} \log \delta_n \}
\end{align*}
\]

where \( \alpha_n := \sqrt{n}(P_n - P) \), \( P_n \) denotes the empirical measure, and \( C_1, C_2 \) are some finite constants. Here, the second inequality follows by a straightforward calculation and the first inequality is due to the fact that for \( \delta_n \) sufficiently small by definition

\[
J_{\|}(\delta_n, \mathcal{F}_n, L^2(P)) = \int_0^{\delta_n} \sqrt{1 + \log N_{\|}(\varepsilon D, \mathcal{F}_n, L^2(P))} d\varepsilon \leq C_1 \int_0^{\delta_n} |\log \varepsilon| d\varepsilon.
\]

Now under the assumption on \( \delta_n \), the indicator in the last line will be zero for \( n \) large enough and thus the proof is complete. \( \square \)

**Lemma B.4.** Assume that \( \kappa \) is a symmetric, uniformly bounded density with support \([-1, 1]\) and let \( b_n = o(1) \). Introduce the notation \( Q_{G, \kappa, \tau, b_n}(F) := G^{-1}(H_{G, \kappa, \tau, b_n}(F)) \).

(a) If the function \( F : [0, 1] \to \mathbb{R} \) is strictly increasing and \( F^{-1} \) is \( k \) times continuously differentiable in a neighborhood of the point \( \tau \), we have

\[
H_{id, \kappa, \tau, b_n}(F) = F^{-1}(\tau) + \sum_{i=1}^{k} \frac{b_i}{i!}(F^{-1})^{(i)}(\tau) \mu_{i+1}(\kappa) + R_n(\tau)
\]
with \(|R_n| \leq C_{k}(\kappa)|b|^k \sup_{|s-\tau| \leq b_n} |(F^{-1})^{(k)}(\tau) - (F^{-1})^{(k)}(s)|, \mu_{k}(\kappa) := \int u^{\kappa}(u) du\) and a constant \(C_{k}\) depending only on \(k\) and \(\kappa\). In particular, if \(F : \mathbb{R} \rightarrow [0, 1]\) is strictly increasing and \(F^{-1}\) is two times continuously differentiable in a neighborhood of \(\tau\) and \(G : [0, 1] \rightarrow \mathbb{R}\) is two times continuously differentiable in a neighborhood of \(F^{-1}(\tau)\) with \(G'(F^{-1}(\tau)) > 0\), we have

\[
|F^{-1}(\tau) - Q_{G,\kappa,\tau,b_n}(F)| \leq R_{n,2} = Cb_n^2 \sup_{|s-\tau| \leq R_{n,1}} \sup_{|s-\tau| \leq b_n} |(G^{-1})'(s)| (\sup_{|s-\tau| \leq b_n} |(G \circ F^{-1})''(s)|),
\]

for some constant \(C\) that depends only on \(\kappa\) where \(R_{n,1} := Cb_n^2 \sup_{|s-\tau| \leq b_n} |(G \circ F^{-1})''(s)|\).

(b) Assume that \(\kappa\) is additionally differentiable with Lipschitz-continuous derivative and that the functions \(G, G^{-1}\) have derivatives that are uniformly bounded on any compact subset of \(\mathbb{R}\) [the bound is allowed to depend on the interval]. Then for any increasing function \(F\) with uniformly bounded first derivative we have \(|H(F_1) - H(F_2)| \leq R_{n,3} + R_{n,4}\) and

\[
|Q_{G,\kappa,\tau,b_n}(F_1) - Q_{G,\kappa,\tau,b_n}(F_2)| \leq \sup_{u \in \mathbb{U}(H(F_1), H(F_2))} |(G^{-1})'(u)| (R_{n,3} + R_{n,4}),
\]

where the constant \(C\) depends only on \(\kappa\), \(\mathbb{U}(a, b) := [a \land b, a \lor b]\), and

\[
R_{n,3} := \frac{Cc_n}{b_n} \|F_1 - F_2\|_{\infty} \sup_{|v-\tau| \leq c_n} |(G \circ F^{-1})'(v)|,
R_{n,4} := \frac{R_{n,3} \|F_1 - F_2\|_{\infty} + \|F_1 - F\|_{\infty}}{b_n}
\]

with \(c_n := b_n + 2\|F_1 - F_2\|_{\infty} + \|F_1 - F\|_{\infty}\).

(c) If additionally to the assumptions made in (b), the function \(F_1\) is two times continuously differentiable in a neighborhood of \(F^{-1}(\tau)\) with \(F_1'(F_1^{-1}(\tau)) > 0\) and \(G\) is two times continuously differentiable in a neighborhood of \(F_1^{-1}(\tau)\) with \(G'(F_1^{-1}(\tau)) > 0\), we have

\[
Q_{G,\kappa,\tau,b_n}(F_1) - Q_{G,\kappa,\tau,b_n}(F_2) = \frac{1}{F_1'(F_1^{-1}(\tau))} \int_{-1}^{1} \kappa(v) \left( F_2(F_1^{-1}(\tau + vb_n)) \right. \\
- \left. F_1(F_1^{-1}(\tau + vb_n)) \right) dv + R_n,
\]

where

\[
|R_n| \leq R_{n,5} + R_{n,6} + \frac{Cb_n \sup_{|s-\tau| \leq b_n} (G \circ F^{-1})''(s) \|F_1 - F_2\|_{\infty} + R_{n,4}}{G'(F_1^{-1}(\tau))}
\]

with a constant \(C\) depending only on \(\kappa\) and

\[
R_{n,5} := \frac{1}{2} \sup_{u \in \mathbb{U}(H(F_1), H(F_2))} |(G^{-1})''(u)| (H(F_1) - H(F_2))^2
\]
\[ R_{n,6} := \sup_{u \in U(H(F_1)G(F_1^{-1})(\tau))} |(G^{-1})''(u)| \cdot |H(F_1) - G(F_1^{-1})(\tau)| \times |H(F_1) - H(F_2)|. \]

**Proof.** The proof of the first part of (a) is essentially a Taylor expansion. Details can be found in the proof of Lemma A.4 in Volgushev (2006). For a proof of the second part of (a), observe that by definition \( H_{G,\kappa,\tau,b_n}(F) = H_{id,\kappa,\tau,b_n}(F \circ G^{-1}) \). Together with the first part we obtain

\[ |H_{id,\kappa,\tau,b_n}(F \circ G^{-1}) - G \circ F^{-1}(\tau)| \leq Cb_n^2 \sup_{|s - \tau| \leq b_n} |(G \circ F^{-1})''(s)| =: R_{n,1} \]

which yields

\[
|G^{-1}(H_{G,\kappa,\tau,b_n}(F)) - F^{-1}(\tau)| \\
\leq |(G^{-1})'(\xi)| \cdot |H_{id,\kappa,\tau,b_n}(F \circ G^{-1}) - G(F^{-1}(\tau))| \\
\leq Cb_n^2 \sup_{|s - \tau| \leq b_n} |(G^{-1})'(s)| \sup_{|s - \tau| \leq b_n} |(G \circ F^{-1})''(s)| =: R_{n,2}.
\]

The proof of (a) is thus complete.

From now on, drop the index of \( H \) for the sake of a simpler notation. For a proof of (b), observe the decomposition

\[
H(F_1) - H(F_2) = -\frac{1}{b_n} \int_0^1 \kappa \left( \frac{F_1(G^{-1}(u)) - \tau}{b_n} \right) (F_1(G^{-1}(u)) - F_2(G^{-1}(u)))du \\
- \frac{1}{b_n} \int_0^1 \left[ \kappa \left( \frac{\xi(u) - \tau}{b_n} \right) - \kappa \left( \frac{F_1(G^{-1}(u)) - \tau}{b_n} \right) \right] \\
\times (F_1(G^{-1}(u)) - F_2(G^{-1}(u)))du
\]

for some \( |\xi(u) - F_2(G^{-1}(u))| \leq |F_1(G^{-1}(u)) - F_2(G^{-1}(u))| \). This yields the bound

\[
|H(F_1) - H(F_2)| \leq \frac{1}{b_n} \int_0^1 \kappa \left( \frac{F_1(G^{-1}(u)) - \tau}{b_n} \right) + \left| \kappa \left( \frac{\xi(u) - \tau}{b_n} \right) - \kappa \left( \frac{F_1(G^{-1}(u)) - \tau}{b_n} \right) \right| du \times \| F_1 - F_2 \|_\infty.
\]

Next, observe that by assumption \( \kappa \) is Lipschitz continuous and thus we have the inequality

\[
\left| \kappa \left( \frac{\xi(u) - \tau}{b_n} \right) - \kappa \left( \frac{F_1(G^{-1}(u)) - \tau}{b_n} \right) \right| \\
\leq \frac{L|\xi(u) - F_1(G^{-1}(u))|}{b_n} \left( I\{|F_1(G^{-1}(u)) - \tau| \leq b_n\} + I\{|\xi(u) - \tau| \leq b_n\} \right) \\
\leq \frac{2L\|F_1 - F_2\|_\infty}{b_n} I\{|F_1(G^{-1}(u)) - \tau| \leq b_n + 2\|F_1 - F_2\|_\infty\} \\
\leq \frac{2L\|F_1 - F_2\|_\infty}{b_n} I\{|F(G^{-1}(u)) - \tau| \leq b_n + 2\|F_1 - F_2\|_\infty + \|F_1 - F\|_\infty\}.
\]
Similarly
\[
\left| \kappa \left( \frac{F_1(G^{-1}(u)) - \tau}{b_n} \right) - \kappa \left( \frac{F(G^{-1}(u)) - \tau}{b_n} \right) \right| \leq \frac{2L \|F_1 - F\|_\infty}{b_n} I \{ |F(G^{-1}(u)) - \tau| \leq b_n + \|F_1 - F\|_\infty \},
\]
and moreover
\[
\left| \kappa \left( \frac{F(G^{-1}(u)) - \tau}{b_n} \right) \right| \leq CI \{ |F(G^{-1}(u)) - \tau| \leq b_n \}.
\]
Define \( c_n := b_n + 2\|F_1 - F_2\|_\infty + \|F_1 - F\|_\infty \). Note that the monotonicity of \( F, G \) implies
\[
\{ u : |F(G^{-1}(u)) - \tau| \leq c_n \} \subseteq [G(F^{-1}(\tau - c_n)), G(F^{-1}(\tau + c_n))]
\]
and
\[
|G(F^{-1}(\tau + c_n)) - G(F^{-1}(\tau - c_n))| \leq 2c_n \sup_{|v - \tau| \leq c_n} |(G \circ F^{-1})'(v)|.
\]
In particular, this implies the estimate
\[
\int_0^1 I \{ |F(G^{-1}(u)) - \tau| \leq c_n \} du \leq 2c_n \sup_{|v - \tau| \leq c_n} |(G \circ F^{-1})'(v)|.
\]
Summarizing, we have obtained the bound \( |H(F_1) - H(F_2)| \leq R_{n,3} + R_{n,4} \) where \( C \) denotes some constant depending only on the kernel \( \kappa \). Assertion (b) follows from this estimate and a Taylor expansion of \( G^{-1} \).

For a proof of assertion (c), note that after a substitution
\[
\frac{1}{b_n} \int_0^1 \kappa \left( \frac{F_1(G^{-1}(u)) - \tau}{b_n} \right) (F_1(G^{-1}(u)) - F_2(G^{-1}(u))) du
\]
\[
= \int_{-1}^1 (G \circ F_1^{-1})'(\tau + vb_n) \kappa(v) \left( F_2(F_1^{-1}(\tau + vb_n)) - F_1(F_1^{-1}(\tau + vb_n)) \right) dv
\]
\[
= (G \circ F_1^{-1})'(\tau) \int_{-1}^1 \kappa(v) \left( F_2(F_1^{-1}(\tau + vb_n)) - F_1(F_1^{-1}(\tau + vb_n)) \right) dv + r_n
\]
where
\[
|r_n| \leq Cb_n \sup_{|s - \tau| \leq b_n} |(G \circ F_1^{-1})''(s)| \cdot \|F_1 - F_2\|_\infty
\]
by a Taylor expansion of \((G \circ F_1^{-1})'\). A Taylor expansion of \( G^{-1} \) yields
\[
\left\| G^{-1}(H(F_1)) - G^{-1}(H(F_2)) - (G^{-1})'(H(F_1))(H(F_1) - H(F_2)) \right\| \leq \frac{1}{2} \sup_{u \in [H(F_1), H(F_2)]]} |(G^{-1})''(u)|(H(F_1) - H(F_2))^2
\]
where $U(a, b) := [a \land b, a \lor b]$. A Taylor expansion yields

$$\left| (G^{-1})'(H(F_1)) - (G^{-1})'(G(F_1^{-1})(\tau)) \right| \leq \sup_{u \in U(H(F_1), G(F_1^{-1})(\tau))} |(G^{-1})''(u)| \cdot \left| H(F_1) - G(F_1^{-1})(\tau) \right|$$

and combining this with the results obtained so far we arrive at

$$\left| Q(F_1) - Q(F_2) + \frac{1}{F'_1(F_1^{-1}(\tau))} \int_{-1}^{1} \kappa(v) \left( F_2(F_1^{-1}(\tau + vb_n)) - F_1(F_1^{-1}(\tau + vb_n)) \right) dv \right|$$

$$\leq \left| G^{-1}(H(F_1)) - G^{-1}(H(F_2)) - (G^{-1})'(H(F_1))(H(F_1) - H(F_2)) \right|$$

$$+ |H(F_1) - H(F_2)| \cdot \left| (G^{-1})'(H(F_1)) - (G^{-1})'(G \circ F_1^{-1}(\tau)) \right|$$

$$+ \left| \frac{H(F_1) - H(F_2)}{G'(F_1^{-1}(\tau))} + \frac{1}{F'_1(F_1^{-1}(\tau))} \int_{-1}^{1} \kappa(v) \left( F_2(F_1^{-1}(\tau + vb_n)) - F_1(F_1^{-1}(\tau + vb_n)) \right) dv \right|$$

$$\leq R_{n,5} + R_{n,6} + \frac{C b_n \sup_{|s-\tau| \leq b_n} (G \circ F_1^{-1})''(s) \left\| F_1 - F_2 \right\|_\infty + R_{n,4}}{G'(F_1^{-1}(\tau))}.$$ 

This completes the proof. \qed

**Appendix C: Bootstrap validity**

In this section we sketch a proof of conditional weak convergence of the bootstrap process $\sqrt{n}T_n^*$ to the weak limit $\mathbb{T}$ of $\sqrt{n}T_n$ under $H_0$, in probability. Let $E^*$ and $\text{Cov}^*$ denote expectation and covariance with respect to the conditional probability $P(\cdot \mid Y_n)$, given the original sample $Y_n = \{(Y_i, X_i, Z_i) \mid i = 1, \ldots, n\}$.

Introduce $V_i = (I(U_i \leq \tau) - \tau) / (\tau(1-\tau))^{1/2}$, then we have the decomposition

$$T_n^*(\Theta, z) = \sqrt{\tau(1-\tau)} \left( T_n^{(1)*}(\Theta, z) + T_n^{(2)*}(\Theta, z) + R_n^{(1)*}(\Theta, z) + R_n^{(2)*}(\Theta, z) \right),$$

where

$$T_n^{(1)*}(\Theta, z) = \frac{1}{n} \sum_{i=1}^{n} V_i \left\{ I\{X_i \in \Theta\} \left( I\{Z_i \leq z\} - F_{Z|X_i}(z|X_i, 0) \right) 
- E \left[ I\{X \in \Theta\} \left( I\{Z \leq z\} - F_{Z|X}(z|X, 0) \right) \right] \right\}$$

$$T_n^{(2)*}(\Theta, z) = \frac{1}{n} \sum_{i=1}^{n} V_i E \left[ I\{X \in \Theta\} \left( I\{Z \leq z\} - F_{Z|X}(z|X, 0) \right) \right].$$
\[ R_n^{(1)*}(\Theta, z) = \frac{1}{n} \sum_{i=1}^{n} V_i I\{X_i \in \Theta\} \left( F_{Z|X,\varepsilon}(z|X_i, 0) - \hat{F}_{Z|X,\varepsilon}(z|X_i, 0) \right) \]

\[ R_n^{(2)*}(\Theta, z) = \frac{1}{n} \sum_{i=1}^{n} \left( I\{U_i \leq \hat{\tau} - \hat{\tau} - I\{U_i \leq \tau\} + \tau\} I\{X_i \in \Theta\} \right) \times \left( I\{Z_i \leq z\} - \hat{F}_{Z|X,\varepsilon}(z|X_i, 0) \right). \]

Note that \( V_1, \ldots, V_n \) are bounded independent and identically distributed random variables with expectation zero and unit variance and are independent of the sample \((Y_i, X_i, Z_i), i = 1, \ldots, n\). Thus we have \( E^*[T_n^{(1)*}(\Theta, z)] = E^*[T_n^{(2)*}(\Theta, z)] = 0 \). With the conditional multiplier central limit theorem Th. 2.9.7 in van der Vaart and Wellner (1996) weak convergence of \( \sqrt{n}T_n^{(1)*} \) to a centered Gaussian process for almost all samples \((Y_1, X_1, Z_1), (Y_2, X_2, Z_2), \ldots \) follows directly. Further, \( \sqrt{n}T_n^{(2)*} \) is independent of the sample \((Y_1, X_1, Z_1), \ldots \) and converges weakly to

\[ \zeta E \left[ I\{X \in \Theta\} \left( I\{Z \leq z\} - F_{Z|X,\varepsilon}(z|X, 0) \right) \right], \]

where \( \zeta \) is standard normally distributed. From this one can deduce conditional weak convergence of \( \sqrt{n}(T_n^{(1)*} + T_n^{(2)*}) \) to a Gaussian process for almost all \((Y_1, X_1, Z_1), (Y_2, X_2, Z_2), \ldots \). The conditional covariance is

\[ nCov^* \left( T_n^{(1)*}(\Theta_1, y) + T_n^{(2)*}(\Theta_1, y), T_n^{(1)*}(\Theta_2, z) + T_n^{(2)*}(\Theta_2, z) \right) \]

\[ = \frac{1}{n} \sum_{i=1}^{n} I\{X_i \in \Theta_1 \cap \Theta_2\} \left( I\{Z_i \leq y\} - F_{Z|X,\varepsilon}(y|X_i, 0) \right) \times \left( I\{Z_i \leq z\} - F_{Z|X,\varepsilon}(z|X_i, 0) \right) \]

and converges almost surely to \( k(\Theta_1, y, \Theta_2, z)/(\tau(1 - \tau)) \) as defined in Corollary 3.3. Thus weak convergence of \( \sqrt{n}T_n \) to \( \mathbb{T} \) follows if we show

\[ \sup_{z, \Theta} |R_n^{(\ell)*}(z, \Theta)| = o_P\left( \frac{1}{\sqrt{n}} \right) \text{ for } \ell = 1, 2. \quad (B.4) \]

For \( \ell = 1 \) this can be deduced similarly to (but easier than) the proof of Theorem 2 in Delgado and González-Manteiga (2001). The main arguments are as follows. Note that

\[ R_n^{(1)*}(\Theta, z) = \frac{1}{n^2 a^\varepsilon e} \sum_{i=1}^{n} \sum_{j=1}^{n} V_i I\{X_i \in \Theta\} \frac{1}{f_{X,\varepsilon}(X_i, 0)} \times \left( F_{Z|X,\varepsilon}(z|X_i, 0) - I\{Z_i \leq z\} \right) L\left( \frac{X_j - X_i}{a} \right) N\left( \frac{\hat{\xi}_j}{e} \right), \]
where
\[
\hat{f}_{X,\varepsilon}(x, y) = \frac{1}{n a d e} \sum_{j=1}^{n} L \left( \frac{X_j - x}{a} \right) N \left( \frac{\hat{\varepsilon}_j - y}{e} \right)
\]
is a kernel estimator for the joint density of \(X, \varepsilon\) and is uniformly consistent (under typical assumptions on the kernels \(L\) and \(N\) and the bandwidths \(a\) and \(e\)). It can be replaced by \(f_{X,\varepsilon}(x, y)\) in \(R_n^{(1)*}(\Theta, z)\) without changing the asymptotic order. Further, by applying a Taylor expansion for the kernel \(N\) the residuals \(\hat{\varepsilon}_j\) can be replaced by the true errors \(\varepsilon_j\) and the term obtained for \(i = j\) in the representation of \(R_n^{(1)*}\) can be bounded by a constant times
\[
\frac{1}{n a d e} \sum_{i=1}^{n} |V_i| \frac{1}{f_{X,\varepsilon}(X_i, 0)} N \left( \frac{\varepsilon_i}{e} \right)
\]
which is of order \(O_P((n a d)^{-1})\) and hence \(o_P(n^{-1/2})\) by proper choice of the bandwidth. Thus it remains to consider the U-process
\[
U_n(\Theta, z) = \frac{1}{n^2 a d e} \sum_{i=1}^{n} \sum_{j=1}^{n} V_i I\{X_i \in \Theta\} \left( F_{Z|X,\varepsilon}(z|X_i, 0) - I\{Z_j \leq z\} \right)
\]
\[
\times L \left( \frac{X_j - X_i}{a} \right) N \left( \frac{\varepsilon_j}{e} \right).
\]
For fixed \((\Theta, z)\) Hoeffding’s decomposition shows that the dominating term is
\[
\frac{1}{n a d e} \sum_{i=1}^{n} V_i I\{X_i \in \Theta\} \int \left( F_{Z|X,\varepsilon}(z|X_i, 0) - F_{Z|X,\varepsilon}(z|x, 0) \right)
\]
\[
\times L \left( \frac{x - X_i}{a} \right) N \left( \frac{y}{e} \right) f_{X,\varepsilon}(x, y) d(x, y)
\]
with a variance bounded by
\[
\frac{1}{n} \int \left( \frac{1}{a^d e} \int \left( F_{Z|X,\varepsilon}(z|t, 0) - F_{Z|X,\varepsilon}(z|x, 0) \right) L \left( \frac{x - t}{a} \right) N \left( \frac{y}{e} \right) f_{X,\varepsilon}(x, y) d(x, y) \right)^2 dt,
\]
which is of order \(o(n^{-1})\) by continuity of \(t \mapsto F_{Z|X,\varepsilon}(z|t, 0)\). Thus, \(U_n(z, \Theta) = o_P(n^{-1/2})\). Uniformity of the arguments in \(z\) and \(\Theta\) and hence \((B.4)\) for \(\ell = 1\) can be obtained with methods as in Delgado and González-Manteiga (2001) (compare their term \(A_{2n}^1\) in the proof of Th. 2).

For the second remainder term we use the simple bound
\[
\sup_{\Theta, z} |R_n^{(2)*}(\Theta, z)| \leq \frac{1}{n} \sum_{i=1}^{n} I\{\tau < U_i \leq \hat{\tau} \text{ or } \hat{\tau} < U_i \leq \tau\} + |\hat{\tau} - \tau|.
\]
Note that from the proof of the main result it follows that \( \hat{\tau} = \tau + o_P(n^{-1/2}) \) (consider \( T_n(\Theta, z) \) with \( \Theta = \mathbb{R}^d, z = \infty \) componentwise). Thus for all \( \eta > 0 \) we have

\[
P \left( \sup_{\Theta, z} |R_n^{(2)}(\Theta, z)| \geq \frac{\eta}{\sqrt{n}} \right) \leq P \left( \frac{1}{n} \sum_{i=1}^{n} I\{\hat{\tau} < U_i \leq \hat{\tau} + \tau \} - \tau + \frac{\eta}{4n} \right) + P \left( \frac{1}{n} \sum_{i=1}^{n} I\{\hat{\tau} < U_i \leq \hat{\tau} \} - \tau + \frac{\eta}{4n} \right)
\]

\[
\leq P \left( \sup_{|t-t'| \leq n^{-1/2}} |G_n(t) - G_n(t')| \geq \frac{\eta}{4n} \right) + o(1) = o(1),
\]

where the last equality and thus (B.4) for \( \ell = 2 \) follows from asymptotic stochastic equicontinuity of the standard uniform empirical process \( G_n(t) = n^{-1/2} \sum_{i=1}^{n} (I\{U_i \leq t\} - t), t \in [0,1] \).
