Activated carbon fiber/Fe₃O₄ composite with enhanced electromagnetic wave absorption properties

Qilong Sun, Lei Sun, YingYing Cai, Tao Ji and Guangyu Zhang

To obtain a low-density material that is capable of absorbing electromagnetic waves over a wide bandwidth, an activated carbon fiber/Fe₃O₄ composite material (ACF/Fe₃O₄) was prepared using an in situ reduction method. Scanning electron microscopy images show that Fe₃O₄ nanoparticles, approximately 10–40 nm in size, were spread uniformly over the surface of the ACF. The resulting composite exhibited superparamagnetic behavior at room temperature. The ability of the ACF and ACF/Fe₃O₄ composite to absorb electromagnetic waves over a frequency range of 8.2–18 GHz was measured using the arch method. The results showed that the maximum reflectivity of an ACF felt was −12.9 dB at 18 GHz, and the effective microwave-absorbing bandwidth (R < −10 dB) was 1.9 GHz (16.10–18 GHz). The absorption performance of the ACF was greatly enhanced by being loaded with Fe₃O₄ nanoparticles; the maximum reflectivity of the 2 mm layer of the ACF/Fe₃O₄ composite was −30.07 dB at 16.45 GHz, and the effective bandwidth (R < −10 dB) increased to 8.62 GHz (9.38–18 GHz). Coating with nano-Fe₃O₄ magnetic particles can effectively improve the absorption of electromagnetic waves by the ACF, and this technique therefore has great potential for application to the field of electromagnetic shielding.

Introduction

With the rapid development of electronic technology, electromagnetic interference has become the fourth major type of pollution, after water pollution, atmospheric pollution, and noise pollution, and constitutes a serious threat to human health. Meanwhile, the leakage of electromagnetic waves also affects the normal operation of electronic equipment, resulting in serious losses. The development of a microwave-absorbing material that is thin while having a low density, as well as having a broad, strong absorption band, would be of great significance to the improvement of the quality of human life and for the industrial production of electromagnetic protection equipment and materials.

In general, magnetic particles such as Fe₇, Co₁, Ni₇, Fe₂O₃, and carbonyl iron particles can be used to absorb electromagnetic waves due to their highly complex permeability; however, their high densities and narrow absorption bands limit their applicability. Electromagnetic wave loss is such that the overall loss is determined by both the magnetic and electrical losses. Combining a magnetic material with a dielectric can not only reduce the weight but also achieve better microwave absorption through impedance matching. Carbon fiber is a type of dielectric-loss material with a carbon content of more than 95%. It offers the advantages of low density and a low coefficient of thermal expansion, as well as good absorbency of electromagnetic waves at high frequencies, relative to magnetic metal materials. However, not every type of carbon fiber can be used as a microwave-absorbing material; this depends on the conductivity of the carbon fiber. An excessively high electrical conductivity causes the carbon fibers to reflect electromagnetic waves, which strongly affects their ability to absorb microwaves. Therefore, only carbon fibers that have been specially treated can be used to absorb microwaves. Wu et al. suggested that the use of activated carbon fiber (ACF) is an effective approach to increasing electromagnetic wave absorption because of the multiple reflections and longer propagation distance inside the composite.

In the present study, we prepared a lightweight composite material, capable of absorbing electromagnetic waves over a wide bandwidth, by coating ACF with Fe₃O₄ magnetic particles. The Fe₃O₄ magnetic particles were applied using an in situ reduction method, and the reflectivities of the ACF and ACF/Fe₃O₄ felts over a frequency range of 8.2–18 GHz were studied using the arch method.

Experimental

Materials

Viscose fiber felt (Jiangsu Sutong Carbon Fiber Co., Ltd.), phosphoric acid (Nantong Qixiang Biotechnology Co., Ltd.), anhydrous...
ferric chloride (FeCl₃; Shanghai Runjie Chemical Reagent Co., Ltd.), and glucose monohydrate (C₆H₁₂O₆·H₂O; Shanghai Runjie Chemical Reagent Co., Ltd.), all of reagent grade, were purchased and used without any further purification.

**Preparation of ACF felt**
The viscose fiber felt samples were cleaned by ultrasonication in water for 30 min to remove the textile oiling agent. Phosphoric acid was employed as an activator to prepare the viscose-based ACF. The dried viscose fiber felts were soaked in phosphoric acid solution (2.0 mol L⁻¹) for 2 h and then dried at 60 °C. The dried sample was then placed in a vacuum muffle furnace and carbonized under a nitrogen atmosphere. The carbonization temperature was 650 °C; the heating rate was 10 °C min⁻¹, and the holding time was 1 h. This produced the ACF felt.

**Preparation of ACF/Fe₃O₄ felt**
The ACF felts were immersed in saturated FeCl₃ solution (1000 mL) at 60 °C for 2 h, then 15 g of glucose monohydrate was added, followed by ultrasonication for 1 h. The sample was dried at 60 °C, after which it was subjected to a further high-temperature treatment in a vacuum muffle furnace; the treatment temperature was 750 °C, the heating rate was 15 °C min⁻¹, and the holding time was 30 min. This produced ACF/Fe₃O₄ felts. The preparation process is illustrated in Fig. 1.

**Characterization**
The surface morphologies of ACF and ACF/Fe₃O₄ were characterized using field-emission scanning electron microscopy (FESEM; S-4800, Hitachi High-Technologies) with an acceleration voltage of 3 kV.

**Results and discussion**
**Phase composition and morphology**
The XRD pattern for the ACF is shown in Fig. 3(a). ACF has a typical amorphous structure, with two strong amorphous diffraction peaks at 2θ = 23° and 2θ = 44°, corresponding to the (002) and (101) crystal planes, respectively. Fig. 3(b) shows the XRD pattern for ACF/Fe₃O₄. New crystals appear at 2θ = 30.42°, 35.74°, 40.28°, 43.46°, 53.94°, 57.24°, and 62.90°, which...
correspond, respectively, to the (220), (311), (400), (422), (511), and (400) crystal planes of the face-centered cubic Fe₃O₄ crystals [JCPDS no. 19-0269]. It is noted that glucose plays an important role in Fe₃O₄ formation because it can decompose to reductive CO gas, which can fully reduce Fe³⁺ to Fe²⁺. This explains why no Fe₂O₃ signal are found in the XRD pattern. The particle size of Fe₃O₄ at the (311) crystal surface, calculated using the Scherrer equation, is approximately 16.18 nm, indicating that the Fe₃O₄ particles prepared using this method will be nano-sized.

Note that there are some miscellaneous peaks, which may indicate the presence of FeOOH, FeO, Fe₂C, or Fe(OH)₂. FeOOH and Fe(OH)₂ are likely to be the products of trace amounts of Fe₃O₄ undergoing acid–base reactions; FeO and Fe₂C may be derived from the carbonization reactions, caused by the reaction of Fe₃O₄ with carbon (C) in the raw material or with the cracked gas containing carbon and oxygen.

The microstructures of the ACF and ACF/Fe₃O₄ were characterized by FESEM. Fig. 4(a) shows a SEM image of the ACF. The surface of the ACF is relatively smooth, and there are no particles on the surface that would indicate residual impurities. Fig. 4(b) and (c) shows SEM images of ACF/Fe₃O₄ at different magnifications. Most of the Fe₃O₄ particles are distributed uniformly over the surface of the ACF. The Fe₃O₄ particles are irregular in shape while their sizes are within a range of 15–60 nm, which corresponds to the particle size as calculated from the XRD pattern via the Scherrer equation. Fig. 4(d) showed that the as-prepared ACF/Fe₃O₄ felt was easy to bend, indicative of good flexibility after the treatment.

Chemical composition

The elemental compositions and chemical states of the ACF and ACF/Fe₃O₄ were characterized by XPS. Fig. 5(a) shows the XPS survey spectra for the ACF and ACF/Fe₃O₄. There are two distinct peaks in these spectra, corresponding to C 1s and O 1s, respectively. An additional distinct peak appears in the XPS spectrum for ACF/Fe₃O₄, which corresponds to Fe 2p. The high-resolution Fe 2p spectrum is shown in Fig. 5(b); the two peaks at binding energies of 710.9 eV and 724.5 eV correspond to the Fe 2p₃/2 and Fe 2p₁/2 spin–orbit peaks, respectively, indicating the formation of Fe₃O₄. Fig. 5(c), (d) shows the O 1s XPS spectra for the ACF and ACF/Fe₃O₄ with peak-fitting curves; three peaks are visible for both the ACF and ACF/Fe₃O₄, at 531.2 eV, 532.3 eV, and 533.2 eV, corresponding to O=C=O, C=O, and C-O, respectively. Meanwhile, the distinct peak at 530.5 eV in the O 1s spectra of ACF/Fe₃O₄ is assigned to the Fe–O bonds in Fe₃O₄, which further demonstrates the existence of Fe₃O₄.

Magnetic and electromagnetic wave absorption properties

Fig. 6 shows the magnetic hysteresis loop for ACF/Fe₃O₄ over a range of –20 000 to 20 000 Oe at room temperature; its shape is a typical S-curve, corresponding to the superparamagnetic behavior. The magnetic properties including the saturation magnetization Mₛ, magnetic coercivity H_C, and remanent...
magnetization $M_r$ are 22 emu g$^{-1}$, 114 Oe and 3.4 emu g$^{-1}$, respectively. The $M_s$ of ACF/Fe$_3$O$_4$ is lower than that of bulk Fe$_3$O$_4$ (ca. 84.5 emu g$^{-1}$), which can be explained by the small size of the Fe$_3$O$_4$ nanoparticles and the addition of ACF, which is in good agreement with the findings of a previous study.\textsuperscript{18}

The microwave-absorbing properties of the ACF/Fe$_3$O$_4$ felt and ACF felt over a frequency range of 8.2–18 GHz are presented as the reflectivity $R$, as measured using the arch method. The arch method is a simple and practical method with which the reflectivity of microwave-absorbing materials can be accurately measured without destroying their structure.\textsuperscript{10,13} Fig. 7(a) shows the microwave absorption/reflectivity curve for ACF felt. The maximum reflectivity is $-12.9$ dB at 18 GHz, and the effective absorption bandwidth ($R < -10$ dB) is 1.9 GHz (16.10–18 GHz).

Fig. 6 Magnetic hysteresis loop of ACF/Fe3O4 at room temperature.

Since ACF is a nonmetallic conductive fiber material with relative high resistance, it can be regarded as a harmonic oscillator in the electromagnetic field, which resonates with incident electromagnetic waves to form a dissipative current. Such generated photocurrent is finally consumed in the material system. ACFs can also be regarded as a dipole under the action of an electromagnetic field. The surface polarization of ACFs further dissipates and decays the photocurrent, converting the electromagnetic energy to other forms of energy under the action of the surrounding matrix. Fig. 7(b) shows the absorption–reflectivity curve of ACF/Fe3O4. The absorption properties of ACF felt are greatly enhanced after loading with Fe3O4 nanoparticles, with the maximum reflectivity reaching −30.7 dB at 16.4 GHz, and the effective absorption bandwidth (R < −10 dB) is 8.2 GHz (9.8–18 GHz). Such enhanced properties are mainly due to the unique electromagnetic properties of nano Fe3O4. The attached Fe3O4 have functions of hysteresis loss, natural resonance and exchange resonance toward electromagnetic wave, resulting in significant attenuation of electromagnetic wave. Besides, magnetic nanoparticles increases the effective contact interface to electromagnetic wave, greatly enhancing the interfacial polarization effect. Thus, the enhanced absorbing property of the composite is owing to the synergistic effect of the electric loss ACF and the magnetic loss Fe3O4.

Conclusion

In summary, an ACF/Fe3O4 composite was successfully prepared using an in situ reduction method. The Fe3O4 was in the form of nanoparticles that are uniformly dispersed over the surface of the ACF and which exhibit superparamagnetism at room temperature. The maximum reflectivity of the ACF reached −12.9 dB at 18 GHz, while the effective absorption bandwidth (R < −10 dB) was 1.9 GHz. The ACF/Fe3O4 felt exhibits greatly improved microwave absorption relative to the ACF felt, with a maximum reflectivity of −30.7 dB at 16.4 GHz and an effective absorption bandwidth (R < −10 dB) of 8.2 GHz, for a thickness of 2 mm. Together, these properties indicate that ACF/Fe3O4 offers the promise of wide-ranging applicability in the fields of absorbing materials and electromagnetic shielding.
