Abstract

Background:

Health literacy is defined as the ability to understand basic health information with such competence as to be able to use this information to enhance health. Lower health literacy is associated with increased post-operative complications, reduced satisfaction and compliance. To ensure accessibility and comprehension by the general public, many international health organisations suggest that health literature has a reading grade level equivalent to the American sixth grade. However, previous studies show that this rarely occurs.

Total ankle replacement (TAR) technology has rapidly progressed with new prosthesis showing increasingly improving outcomes. However, TAR remains a complex procedure which may be challenging to explain to the patient. Thus, many patients will turn to the internet for more information and as a ‘quasi-second opinion’. If the health education materials provided on the internet is not accessible to patients, it can leave them overwhelmed and confused. The aim of the study is to evaluate the readability of information on the internet with regards to Total Ankle Replacement

Methods:

110 websites from the two main search engines (Google and Bing) were assessed using the terms ‘total ankle replacement’ and ‘total ankle arthroplasty’. Once duplicates had been removed and exclusion criteria were applied, 36 unique websites were categorised and underwent analysis using readability software (WEB FX readability tool). The websites were assessed for readability using the Fleisch Reading Ease Score (FRES) and the Reading Grade Level (RGL). A score of greater than 65 for FRES and an RGL of six or less were considered acceptable. Differential and Inferential statistical analysis was performed using SPSS.

Results:

The mean FRES score was 54.95 (SD: ± 13.2); this was significantly below the recognised acceptable standard score of 65 (P<.0001). An ANOVA conducted showed significant difference between FRES scores based on categories (P=.041) with post-hoc testing showing that the difference between commercial and non-physician scores was the most significant (P=.016; CI:3.84-61.66).

The mean RGL was 8.31 (SD: ± 1.95). One-way t-tests showed that these scores were significantly higher than the acceptable standard (P<.0001; CI: 1.64-2.97). ANOVA testing showed a significant difference based on category (P=.028) with post hoc testing showing significant difference between non physician and commercial scores (P=.012, CI: 0.71-9.33).

Conclusion:
The majority of the websites pertaining to total ankle replacement are significantly beyond the comprehension levels of the general public. This will affect the patient’s ability to discern the complexities and potential complications of total ankle arthroplasty, with serious ramifications for consent as well as post-operative rehabilitation and compliance.

**Level of Evidence:** not applicable

### Introduction

Painful ankle osteoarthritis affects approximately 1% of the adult population and is associated with similar levels of psychological distress and physical limitations as have previously been associated with hip and knee arthritis [1-2]. Approximately 70-80% of symptomatic ankle arthritis is post-traumatic, usually associated with a previous ankle fracture [3-5], though repetitive ligamentous injuries have also been linked to long term degeneration of the ankle joint [1, 5-6]. Other rare secondary causes of ankle osteoarthritis include rheumatoid diseases, haemophilia, haemochromotosis, avascular necrosis and post-infective states [7-8].

For most patients, ankle arthritis will present insidiously and non-operative treatment such as bracing, anti-inflammatory medications and intra-articular injections may help to provide pain relief and improve function [9-12]. As the arthritis progresses and conservative treatments fail, patients will turn to surgical options such as ankle arthrodesis and total ankle arthroplasty (TAA) to seek long term pain relief and functional restoration [5].

The primary indication for Total Ankle Replacement (TAR) is end stage ankle arthritis [13]. Previous literature reviews have shown that TAR is a good treatment option for end stage arthritis with the ability to restore function and mobility as well as relieve pain [5, 14-20]. Concerns regarding long term function and mobility with ankle arthrodesis combined with the growing success and evidence in hip and knee ankle arthroplasty have sparked a revolution in developing an equivalent procedure for the ankle [5, 21-22]. Advances in implant design and surgical technique have yield better outcomes in recent years; current literature shows a five-year failure rate of 10 % for TAR compared to a 50% failure rate previously associated with first generation TAA implants [5, 21, 23-24]. Further analysis shows a 77% survival rate at 10 years [23-24]. TAA is also associated with improved post-operative range of motion [14-20] and reduced rates of primary revision compared to ankle arthrodesis [20, 25-27].

Despite these advances, TAR is not without complication. Residual pain is frequent, effecting between 23-60% of recipients’ [24], and this must be communicated to patients pre-operatively within the parameters of their consent. Also, TAA works best in older, lower demand patients, meaning that those who were active or sporty before their arthritis became debilitating may not benefit from this surgical option [1, 5, 28-29]. TAR also requires a demanding post-operative regime that requires strict compliance; this includes plaster cast immobilisation of the limb for six weeks post-operatively [1, 28-30].
As TAR is such a complex operation which is still undergoing development and innovation and is still associated with many biomechanical and surgical complications, it can be difficult to explain this procedure succinctly to the patient. Many patients may become confused or overwhelmed by the information they are being given but may be too embarrassed to seek clarity. Often, these patients will instead access the internet as a means to further understand their procedure and to seek a ‘quasi-second opinion’[31]. Thus, it is of the upmost importance that the information on the internet be as inclusive and accessible to patients as possible to ensure adequate health literacy.

Health literacy is defined as the ability to understand basic health information with such competence as to be able to use this information to enhance health [32]. Lower levels of health literacy have been shown to be associated with higher inpatient hospital service utilisation and increased post-operative complications and costs [33-39]. A lack of health literacy has been shown to significantly impact post-operative rehabilitation compliance, which is particularly pertinent in the case of TAR [37, 28-30]. While simplistic, the key to improving health literacy is to ensure that the materials provided to the health consumers are easily understandable [40]. When we consider that the majority of Americans read at an 8th grade level or lower, it is not difficult to discern that a complex procedure such as TAR may be beyond their comprehension, resulting in negative outcomes [40-43]. Furthermore, TAR has a very specific and lengthy post-operative rehabilitation process which includes several weeks of non-weight bearing [28-30]. A failure to understand this completely will reduce compliance and effect post-operative complication and patient satisfaction rates [37-39]. For all of these reasons the United States Department of Health and Human Services (USDHSS) and National Institute of Health (NIH) has previously recommended that health education material be written at a reading grade level (RGL) of no higher than the sixth grade in a bid to increase accessibility [40-41]. However, previous studies have shown that this level is often exceeded [40, 44-48].

We conducted an extensive literature search and have not found any previously published study which has sought to determine the accessibility of information about TAR on the internet. The aim of this study, therefore, is to evaluate the readability of information on the internet with regards to Total Ankle Replacement/Arthroplasty.

**Methods And Materials**

On a single day in the month of June 2020, we searched for websites on Google and Bing using the terms *total ankle replacement* and *total ankle arthroplasty* [49](SUFE). For each of these searches, the first three pages of returned hits were evaluated (n=110). The reasoning behind this methodology and limit was based on evidence provided by previous studies which have shown that most people do not look beyond the first two pages of website hits and that the majority of people only look at the first page of hits [49-50]. The figures for the returned hits for each search engine and each search term are shown in Table 1.

Duplicate websites were removed first and then the remaining websites were accessed and evaluated based on the exclusion criteria. Medical journals, sites requiring logins or composed solely of videos were
excluded. This is in accordance with previous studies which felt that medical journals would be beyond the capacity of the majority of the population [51]. Following this review of the initial 110 websites, 36 unique webpages underwent further in-depth analysis. A breakdown of this aspect of the methodology is shown via Flow Diagram in Figure 1.

The next step in the analysis was to categorise the 36 included websites by type; following the methodology used in previous studies these categories included academic, physician, non-physician, commercial, media and news, social media and non-specified [49-51]. Any website linked to a university or teaching hospital was considered academic while physician websites referred specifically to any private website owned by a doctor in private practice. Non-physician referred to websites created by other multidisciplinary team members such as physical therapists, radiographers and occupational therapists. Commercial denoted websites which contained advertising or were trying to sell products. Social media was added as a category to acknowledge the increased influence of Facebook, Instagram, Tinder and TikTok in the modern era [49-51]. Finally, sites which did not fall into any of the above categories were classed as unspecified. A list of all included sites is available to review in Appendix 1.

Once classified, the websites were transferred to the online readability software. While there are several types available on the internet, the WEB FX readability software was used in this study. Once uploaded, the readability software was used to calculate and produce a Flesch Reading Ease Score (FRES) and a Reading Grade Level (RGL) for each website [44,52]. The FRES is defined as a determination of how difficult a passage in English is to understand [44-47, 49,51]. Among readability scoring systems, the FRES is the only metric where a higher score indicates an increased readability. A FRES score of 65 or greater is considered acceptable [44,49]. FRES scores between 30-50 are considered difficult to read and scores of less than 30 are considered exceptionally difficult to read and are on par with Harvard Law Review [44,49]. Table 2 shows a complete breakdown of the FRES scoring system [49].

The Reading Grade Level (RGL) is defined as the ‘cumulative score for the readability of a passage’. As previously stated, it is recommended that educational materials generated for health consumers be written at no more than a sixth-grade level of education [40-41].

Statistics were performed using SPSS version 26 (SPSS, Chicago, IL) [53]. The level of significance was set as 5%. To determine whether sites with translation services predicted higher readability scores, 2 sample t tests were used when the data was normally distributed and the Mann-Whitney U test was used when it was not. To determine the difference between categories, ANOVA testing was performed and if this achieved significance, Post-Hoc statistics were undertaken [49,51]. RGL was compared to the 6th grade standard using a one-way t-test. A score of 65 or higher was determined to be acceptable for the FRES test; this acceptable standard was compared to the findings using a one-way t-test [49,51].

Results
A total of 36 unique websites were evaluated using the readability tool. Only six out of the thirty-six websites assessed had a FRES score greater than 65 (16.6%). The mean FRES index was 54.95 (SD: +/- 13.2), which classifies the majority of pieces as ‘fairly difficult to read’ (Table 2). The highest category score as shown in Figure 2 was the non-physician websites. Nine (25%) of the websites reviewed had FRES scores between 30-50 suggesting it would require college level education to be able to read and interpret them. A one-way t-test was performed comparing the FRES mean to the standard; this was significantly below the recognised acceptable index (p<0.0001; 95% CI: -14.52 to -5.58). An ANOVA conducted showed significant difference between FRES scores based on categories (P=0.041) with post-hoc testing showing that the difference between commercial and non-physician scores was the most significant (P=0.016; CI:3.84-61.66).

The mean RGL was 8.31 (SD: +/- 1.95). As shown in Figure 3 the worst RGL scores were in the commercial category while the best were the non-physician websites. This is consistent with the findings in Figure 2 for the FRES. One-way t-tests showed that these scores were significantly higher than the acceptable standard (p<0.0001; CI: 1.64-2.97). ANOVA testing showed a significant difference based on category (p=0.028) with post hoc testing showing significant difference between non physician and commercial scores (p=0.012, CI: 0.71-9.33).

Discussion

TAR is a biomechanical complex and technically challenging procedure which, despite advances, requires strict post-operative program compliance and carries a high risk of complications [28-30]. Thus, if patients are to be able to fully consent to this undertaking, they must have access to reliable information at a level which is easily comprehensible [54].

As observed in previous studies regarding health consumers and the internet, this study has demonstrated that the majority of health education websites regarding TAR exceed the comprehension level of the intended audience [44-50,54]. By failing to adhere to the suggested levels of readability, these websites which are meant to assist patients in understanding their procedure will instead create confusion and anxiety, potentiating the risk of patients developing cyberchondria [55]. This will affect levels of adherence with post-operative care, leading to missed appointments, increased complications, increased hospital re-admission rates and reduced satisfaction with overall treatment outcomes [33-38]. A lack of credible information may affect the patient’s ability to give informed consent in regards to a procedure [39]. As mentioned in the introduction to this article, TAR has an extremely specific post-operative course which includes a significant amount of time non-weight bearing; failure to comply with this due to a lack of understanding and adherence could result in potentially disastrous complications [28-30,37].

It is thus disquieting that the TAR sites evaluated in the study exhibited an average RGL of 8.31, well above those recommended previously [40-41,56-57]. 84% of the materials which underwent analysis scored above the recommended sixth-grade reading level with roughly 25% of the materials evaluated
were scored at readability levels advised for university textbooks. This observation has not only been noted during this specific study but appears as a consistent trend across the literature, supporting a developing worrisome trend that patients will not be able to fully perceive the information regarding TAR [33-39,49].

However, a surprising yet positive aspect which must be noted during this analysis is that although the mean RGL for the TAR websites is above the recommended standard, it is better than the quoted RGL scores for hip and knee arthroplasty in the literature. One paper by Shnaeckel et al analysed nine sets of patient education material for hip and knee arthroplasty and found them to have a cumulative RGL of 10.5 [58]. Similarly, Polishchuk et al published a study in 2012 which estimated Reading Grade Level using a different readability test, the Flesch-Kincaid. Using this test, their study shows an estimated RGL for arthroplasty materials of 11.1 [59]. These figures suggest that while TAR website Reading Grade Levels may not be compliant with the recommended standards, there is an awareness of the need to simplify the information among Foot and Ankle specialists.

This difference could be speculated to be associated with the fact that most orthopaedic surgeons are aware that the majority of patients will know someone within their social or family circles who will have had a hip or knee arthroplasty procedure that they will be able to seek counsel from. However, TAR is a rarer procedure and thus, places more onus on the physician to provide quality information to the patient. This sense of responsibility may be translated into better quality of information being presented on websites, in a bid to communicate more effectively with potential health consumers.

A second concerning trend noted during the analysis is the low FRES scores for the commercial, academic and physician sections shown in Figure 2. The scores for the academic websites, which are affiliated with major teaching hospitals, and for physician sites, which are private foot and ankle specialists, are 55.85 and 53.66 respectively. These FRES score, as noted in Table 2, means that these websites are at a level that requires nearly university level education to be read and understood on the first pass; this is not feasible for many patients and may leave them confused and overwhelmed. The commercial websites have a mean FRES score of 37.97, which means they require higher education to be able to understand these websites. While it must be acknowledged that commercial sites will contain more technical terms than are perhaps found in the other categories, their FRES score is approximately on par with the readability of the score given to Harvard Law Review [44-47,52]. This would be beyond the scope of comprehension for the majority of patients.

There is much scope to further improve the readability of the TAR websites and to make them compliant with the suggested RGL standards. The Agency for Healthcare Research and Quality (AHRQ) has previously advised an approach of assuming all patients and caregivers have difficulty understanding health information and should be communicated with in a manner that anyone can understand [60]. Suggested application of this method for health-related education materials includes the use of diagrams and simple words in a simple conversational style while avoiding jargon [60-65]. Videos could be used to provide an additional further understanding of the procedure and its rehabilitation course.
Orthopaedic surgeons who have a specialised interest in foot and ankle surgery should undertake the responsibility of creating easily comprehensible, high quality education materials based on these guidelines. TAR requires a unique perspective in that the material should not only provide information regarding the surgery itself but should also provide in-depth data about the post-operative care and rehabilitation. Once created, physicians and hospitals should then evaluate these materials using the widely available readability software. Ideally, they should look for a readability software that identifies complex words and offers substitutions; the authors suggest this as most experienced physicians are used to academic script and may be blinded to what constitutes a simple or complex word. An example of this would be substituting the more complex “components” for the simpler, more readily understood words “parts” [49].

The final suggestion the authors submit for improving readability and accessibility is to have websites offer translation options where possible. Society has become extensively multicultural in the last two decades and it is no longer acceptable to assume that English is the first language of every household or health consumer [49].

This study is the first to consider the readability of the information on the internet in regards to TAR. However, it must be acknowledged that there are shortcomings within the study [49]. Materials on the internet are in constant flux yet we limited are search strings to a single day. Thus, we acknowledge that there may be better websites which were missed as a result. Furthermore, the first three pages of each search engine was evaluated for each search term; while this was in keeping with the guidelines followed in previous studies, it may mean that more accessible and readable websites on later pages have been excluded [39,49].

A final limitation is the software used. The readability formulae determine the difficulty of the passage is based on the letters per word, the syllables per word or the number of words per sentence. This means that everyday words such as ‘replacement’ may generate a higher RGL than words with fewer syllables and letters such as ‘physis’ which is a medical term and would be poorly understood by the general public [49].

**Conclusions**

In conclusion, TAR is a complex procedure which has seen improved outcomes as implant quality and surgical technique improve. However, TAR is also associated with significant complications and a difficult post-operative rehabilitation process. It is therefore important that the information regarding this procedure is high yield and easily understood by health consumers.

This study has shown that the data on the internet regarding TAR is relatively inaccessible to the majority of patients and caregivers, with readability scores well above recommended levels. Given the imperative role of health literacy to patient outcomes and the increasing usage of the internet among orthopaedic patients, a substantial amount of work needs to be done to improve the readability of these websites. Until this improves, physicians should err towards their patients away from the internet.

**Tables**

Table (i): Results from searches performed
| Search Engine | Search Term                  | Number of Hits |
|---------------|------------------------------|----------------|
| Google        | Total ankle replacement      | 263,00,000     |
| Google        | Total ankle arthroplasty     | 2,120,000      |
| Bing          | Total ankle replacement      | 5,020,000      |
| Bing          | Total ankle arthroplasty     | 77,900         |

Table (ii): Breakdown of the Flesch Reading Ease Score system. A score of 65 or greater is concerned to be easily accessible to all reading levels [6].

| Score          | School level   | Notes                                                                 |
|----------------|----------------|------------------------------------------------------------------------|
| 100.00–90.00   | 5th grade      | Very easy to read. Easily understood by an average 11-year-old student. |
| 90.0–80.0      | 6th grade      | Easy to read. Conversational English for consumers.                    |
| 80.0–70.0      | 7th grade      | Fairly easy to read.                                                   |
| 70.0–60.0      | 8th & 9th grade| Plain English. Easily understood by 13- to 15-year-old students.       |
| 60.0–50.0      | 10th to 12th grade | Fairly difficult to read.                                        |
| 50.0–30.0      | College        | Difficult to read.                                                     |
| 30.0–0.0       | College graduate | Very difficult to read. Best understood by university graduates.     |
