The Single Server Queue and the Storage Model: Large Deviations and Fixed Points

Moez DRAIEF *

Abstract
We consider the coupling of a single server queue and a storage model defined as a Queue/Store model in [6, 7]. We establish that if the input variables, arrivals at the queue and store, satisfy large deviations principles and are linked through an exponential tilting then the output variables (departures from each system) satisfy large deviations principles with the same rate function. This generalizes to the context of large deviations the extension of Burke’s Theorem derived in [6, 7].

Keywords: Single server queue, storage model, large deviations, Burke’s theorem.

1 Introduction

A celebrated theorem of Burke [1] asserts that when a Poisson process \( \{a_n, n \in \mathbb{Z} \} \) with mean inter-arrival time \( 1/\lambda \) is input to a single server queue whose service times \( \{s_n, n \in \mathbb{Z} \} \) are i.i.d. exponentials (\( \text{./M/1/\infty} \) following the Kendall nomenclature) with mean \( 1/\mu < 1/\lambda \), the equilibrium departure process \( \{d_n, n \in \mathbb{Z} \} \) from the queue is also a mean \( 1/\lambda \) Poisson process. In this sense the mean \( 1/\lambda \) Poisson process is a fixed point for the \( \text{./M/1/\infty} \) operator. In [6, 7], we prove a generalization of Burke’s theorem to the couple of departures and the sequence of times spent at the very back of the queue \( \{r_n, n \in \mathbb{Z} \} \). The sequence \( \{r_n, n \in \mathbb{Z} \} \) can also be seen as the sequence of departures from a storage model, where \( s_n \) is the amount of \( P \) Supplied at slot \( n+1 \), and \( a_n \) is the amount of \( P \) Asked for at the same slot. More precisely, we show that under the conditions of Burke’s theorem the couple of output variables from the Queue/Store model \( \{(d_n, r_n), n \in \mathbb{Z} \} \) has the same law as the couple of input variables \( \{(a_n, s_n), n \in \mathbb{Z} \} \).

In this paper, we consider the fixed point question at large deviations scaling. A similar result has been presented by Ganesh et al. in [11] for discrete-time queues. Assuming that the input variables satisfy a large deviations principle, we show that if their laws are linked through an exponential tilting, then the large deviations principle is preserved by the Queue/Store system (i.e. the output variables satisfy large deviations principles with the same rate functions as the input variables).

This paper is organized as follows: section 2 is devoted to giving some background on large deviations that will be useful for our analysis. The Queue/Store model is presented in section 3. Section 4 focuses on the workload process. We define the concept of effective bandwidth in section 5. Finally, in section 6, we derive a large deviations principle for the output variables of the Queue/Store model (§6.1) and we give the condition on the rate functions of the input variables (§6.2) which are preserved by the Queue/Store operator.

1
2 Large deviations

Let \((\Omega, \mathcal{F}, P)\) be a probability space and \(x = \{x_n, n \in \mathbb{N}\}\) be a sequence of i.i.d. random variables. We define the sequence of partial sums \(X = \{X_n, n \in \mathbb{N}\}\) by

\[
X_n = \sum_{i=1}^{n} x_i.
\]

If \(\mathbb{E}|x_0| < \infty\), then \(X\) satisfies the strong law of large numbers, i.e.,

\[
\lim_{n \to \infty} \frac{X_n}{n} = \mathbb{E}x_0, \text{ a.s.}
\]

We also focus on the fluctuation of a random variable around its mean. Suppose \(\mathbb{E}x_0^2 < \infty\) then the central limit theorem gives the fluctuations of the scale of \(O(1/\sqrt{n})\), of \(X_n/n\) around \(\mathbb{E}x_0\). More precisely the sequence \(\sqrt{n}(X_n/n - \mathbb{E}x_0)\) converges in law a Gaussian random variable with mean zero and variance the one of \(x_0\). Large deviations theory deals with the fluctuations of the scale of \(O(1)\).

**Definition 2.1.** Let \(X\) be a real Hausdorff space. A function \(I: X \to [0, \infty]\) is a rate function if \(I\) is lower semi-continuous, i.e. the sets \(\{x : I(x) \leq \alpha\}\) are closed, for all \(\alpha \in \mathbb{R}\). In addition, if these sets are compact then \(I\) is a good rate function.

**Definition 2.2.** A sequence \(\{x_n, n \in \mathbb{N}\}\) in \(X\) satisfies a large deviations principle with the rate function \(I: X \to [0, \infty]\), if for each Borel subset \(\mathcal{B}\) of \(X\),

\[
- \inf_{x \in \mathcal{B}^\circ} I(x) \leq \liminf_{n \to \infty} \frac{1}{n} \log \mathbb{P}(x_n \in \mathcal{B}) \leq \limsup_{n \to \infty} \frac{1}{n} \log \mathbb{P}(x_n \in \mathcal{B}) \leq - \inf_{x \in \mathcal{B}} I(x),
\]

where \(\mathcal{B}^\circ\) denotes the interior of \(\mathcal{B}\) and \(\mathcal{B}\) its closure.

Throughout the rest of this section, we are interested in real-valued random variables.

**Definition 2.3.** The cumulant generating function of a real-valued random variable \(x\) is given by

\[
\Lambda_X(\theta) = \log \mathbb{E}e^{\theta x}, \quad \forall \theta \in \mathbb{R},
\]

which can be infinite.

Using Hölder’s inequality and Fatou’s lemma, we check that \(\Lambda_X\) is convex, lower semi-continuous and for all \(\theta\) in the effective domain of \(\Lambda_X\) (i.e. \(\{\theta : \Lambda_X(\theta) < \infty\}\)), we have

\[
\Lambda_X'(\theta) = \frac{\mathbb{E}(X_0e^{\theta X_0})}{e^{\Lambda_X(\theta)}}.
\]

We define the Legendre transform of \(\Lambda_X\) as

\[
I_X(x) = \sup_{\theta \in \mathbb{R}} \{\theta x - \Lambda_X(\theta)\}.
\]
The function $I_X$ is positive, convex, and lower semi-continuous. If $\Lambda_X$ is finite at the origin then
$$\Lambda_X'(0) = \mathbb{E}X_0, \text{ and } I_X(\mathbb{E}X_0) = 0.$$ Moreover, we easily check that
$$I_X(x) = \sup_{\theta \geq 0} \{ \theta x - \Lambda_X(\theta) \} \quad \text{for } x \geq \mathbb{E}x_0$$
$$I_X(x) = \sup_{\theta \leq 0} \{ \theta x - \Lambda_X(\theta) \} \quad \text{for } x \leq \mathbb{E}x_0.$$ (2)

We recall the statement of Cramér’s theorem for real-valued random variables.

**Theorem 2.4.** Let $\{x_n, n \in \mathbb{N}\}$ be an i.i.d. sequence of real-valued random variables and let $\Lambda_X$ be its cumulant generating function which we suppose finite at the origin. Then the sequence of random variables $\{X_n/n, n \in \mathbb{N}^*\}$, where $X_n = \sum_{i=1}^{n} x_i$, satisfies a large deviations principle with rate function $I_X$ defined in (1): for each closed subset $F$ of $\mathbb{R}$,
$$\limsup_{n \to \infty} \frac{1}{n} \log \mathbb{P}(S_n \in F) \leq - \inf_{x \in F} I_X(x).$$ (3)

and for each open subset $O$ of $\mathbb{R}$
$$\liminf_{n \to \infty} \frac{1}{n} \log \mathbb{P}(S_n \in O) \geq - \inf_{x \in O} I_X(x).$$ (4)

The inequalities (3) and (4) are known as the upper and lower bounds of the large deviations principle. For the different extensions of Cramér theorem we refer to [5]. We can have a large deviations principle for a couple of independent random variables.

**Theorem 2.5.** Let $\mathcal{X}$ and $\mathcal{Y}$ be two real Hausdorff spaces, and $\{x_n, n \in \mathbb{N}\}$ and $\{y_n, n \in \mathbb{N}\}$ be two sequences satisfying large deviations principles on $\mathcal{X}$ and $\mathcal{Y}$, with rate functions $I_X$ and $I_Y$. Suppose that they are independent, then the sequence $\{(x_n, y_n), n \in \mathbb{N}\}$ satisfies a large deviations principle on $\mathcal{X} \times \mathcal{Y}$ with rate function
$$I_{X,Y}(x, y) = I_X(x) + I_Y(y).$$

In this paper, we will establish large deviations principles relying on indirect methods. Once we have a large deviations principle for one sequence of random variables, we can effortlessly obtain large deviations principles for a whole class of random sequences, namely those obtained via continuous transformations. We present the contraction principle, the tool that enables this.

**Theorem 2.6.** If $\{x_n, n \in \mathbb{N}\}$ satisfies a large deviations principle on $\mathcal{X}$ with rate function $I_X$, and if $f : \mathcal{X} \to \mathcal{Y}$ is a continuous function, then the sequence $\{y_n, n \in \mathbb{N}\}$ defined by $y_n = f(x_n)$ satisfies a large deviations principle on $\mathcal{Y}$ with rate function
$$I_Y(y) = \inf_{x, f(x) = y} I_X(x).$$

Sometimes $f$ is “almost continuous”, i.e. the sequence $\{y_n, n \in \mathbb{N}\}$ is close to a sequence $\{f(x_n), n \in \mathbb{N}\}$, where $f$ is continuous.
Definition-Proposition 2.7. Let \( \{x_n, n \in \mathbb{N}\} \) and \( \{y_n, n \in \mathbb{N}\} \) be two sequences on \( \mathcal{X} \). They are said exponentially equivalent, if for all \( \epsilon > 0 \),

\[
\limsup_{n \to \infty} \log P(\|x_n - y_n\| > \epsilon) = -\infty.
\]

In this case, if \( \{x_n, n \in \mathbb{N}\} \) satisfies a large deviation principle then \( \{y_n, n \in \mathbb{N}\} \) satisfies a large deviations principle, and \( I_X = I_Y \).

Theorem 2.8. If \( \{x_n, n \in \mathbb{N}\} \) satisfies a large deviations principle on \( \mathcal{X} \) with rate function \( I_X \), and if \( \{y_n, n \in \mathbb{N}\} \) and \( \{f(x_n), n \in \mathbb{N}\} \) are exponentially equivalent, with \( f : \mathcal{X} \to \mathcal{Y} \) continuous, then \( \{y_n, n \in \mathbb{N}\} \) satisfies a large deviations principle on \( \mathcal{Y} \) with rate function

\[
I_Y(y) = \inf_{x \in \mathcal{X}, f(x) = y} I_X(x).
\]

For a thorough presentation of large deviations’ results and applications, we refer to [5].

3 The Model

Let \( A = \{A_n, n \in \mathbb{Z}\} \) be a point process and assume that \( A_0 \leq 0 < A_1 \) and \( A_n < A_{n+1} \), \( \forall n \in \mathbb{Z} \). We define the \( \mathbb{R}_+ \)-valued sequence of r.v.’s \( a = \{a_n, n \in \mathbb{Z}\} \) by \( a_n = A_{n+1} - A_n \). Let \( s = \{s_n, n \in \mathbb{Z}\} \) be another \( \mathbb{R}_+ \)-valued sequence of r.v.’s. The sequences \( a \) and \( s \) are the input variables of the model.

Define the sequence of r.v.’s \( \mathcal{D} = \{D_n, n \in \mathbb{Z}\} \) by

\[
D_n = \sup_{k \leq n} \left[ A_k + \sum_{i=k}^n s_i \right].
\]

(5)

A priori the \( D_n \)’s are valued in \( \mathbb{R} \cup \{+\infty\} \). Assume that \( a \) and \( s \) are such that the \( D_n \)’s are almost surely finite. Set \( d_n = D_{n+1} - D_n \) and \( d = \{d_n, n \in \mathbb{Z}\} \). Define an additional sequence of r.v.’s \( r = \{r_n, n \in \mathbb{Z}\} \), valued in \( \mathbb{R}_+ \), by

\[
r_n = \min(D_n, A_{n+1}) - A_n.
\]

(6)

The sequences \( d \) and \( r \) are the output variables of the model. In view of the future analysis, it is convenient to introduce the sequence \( w = \{w_n, n \in \mathbb{Z}\} \) of random variables valued in \( \mathbb{R}_+ \), defined by

\[
w_n = D_n - s_n - A_n = \sup_{k \leq n-1} \left[ \sum_{i=k}^{n-1} (s_i - a_i) \right]^+.
\]

(7)

These random variables satisfy the following recursion (Lindley’s equation)

\[
w_{n+1} = [w_n + s_n - a_n]^+.
\]

(8)

Using the variables \( w_n \), we can give alternative definitions of \( D_n \) and \( r_n \):

\[
\forall l \leq n, \quad D_n = \left[ w_l + A_l + \sum_{i=l}^n s_i \right] \vee \max_{l \leq k \leq n} \left[ A_k + \sum_{i=k}^n s_i \right].
\]

(9)

\[
r_n = \min\{w_n + s_n, a_n\} = s_n + w_n - w_{n+1}.
\]

(10)

We now interpret the variables defined above in two different contexts: a queueing model and a storage model.
3.1 The single-server queue

We are concerned with a single server queue where each customer is characterized by an instant of arrival in the queue and a service demand. Customers are served upon their arrival in the queue and in their order of arrival. Since there is a single server, a customer may have to wait in a buffer before the beginning of its service. Using Kendall’s nomenclature, our model is a ./1/∞/FIFO queue. The customers are numbered by $Z$ according to their order of arrival in the queue (customer 1 being the first one to arrive strictly after instant 0). Let $A_n$ be the instant of Arrival of customer $n$ and $s_n$ its Service time. Then the variables defined in (5)-(8) have the following interpretations:

- $D_n$ is the instant of departure of customer $n$ from the queue, after completion of its service; $\{d_n, n \in Z\}$ is the sequence of inter-departure times;
- $w_n$ is the waiting time of customer $n$ in the buffer between its arrival and the beginning of its service;
- $r_n$ is the time spent by customer $n$ at the very back of the queue.

The variables $\{r_n, n \in Z\}$ are less classical in queueing theory [9].

3.2 The storage model

Some product $P$ is supplied, sold and stocked in a store in the following way: Events occur at integer-valued epochs, called slots. At each slot, an amount of $P$ is supplied and an amount of $P$ is asked for by potential buyers. The rule is to meet all demands, if possible. The demand of a given slot which is not met is lost. The supply of a given slot which is not sold is not lost and is stocked for future consideration.

Let $s_n$ be the amount of $P$ Supplied at slot $n + 1$, and let $a_n$ be the amount of $P$ Asked for at the same slot. In this context, the variables in (5)-(8) can be interpreted as follows:

- $w_n$ is the level of the stock at the end of slot $n$. It evolves according to (8);
- $r_n$ is the demand met at slot $n + 1$, see equation (10); it is the amount of $P$ departing at slot $n + 1$;

The variables $\{D_n, n \in Z\}$ do not have a natural interpretation in this model.

It is important to remark that while the equations driving the single server queue and the storage model are exactly the same, the relevant variables are different. The important variables are the ones corresponding to the departures from the system. The departures are coded in the variables $\{d_n, n \in Z\}$ for the single server queue and in the variables $\{r_n, n \in Z\}$ for the storage model. For a more detailed discussion of these two models we refer to [7].

3.3 Rare events

We recall that $w_n$ is the waiting time of customer $n$ before it starts its service (respectively the level of the stock at the end of slot $n$) and it is given by

$$w_n = (w_{n-1} + s_{n-1} - a_{n-1})^+ = \sup_{m \leq n} \left[ \sum_{k=m}^{n-1} s_k - a_k \right].$$

(11)
We assume that the sequences \( a = \{a_n, n \in \mathbb{Z}\} \) and \( s = \{s_n, n \in \mathbb{Z}\} \) are stationary and ergodic. Under the stability condition \( \mathbb{E}s_0 < \mathbb{E}a_0 \), we can use the above expression of \( w_n \) to give its asymptotic behaviour using the large deviations properties of the input variables \( a = \{a_n, n \in \mathbb{Z}\} \) and \( s = \{s_n, n \in \mathbb{Z}\} \). We start with an example.

**Example** Suppose that customers arrive in a deterministic fashion, i.e. \( a_n = 1, \forall n \), and that the sequence \( \{s_n, n \in \mathbb{Z}\} \) is i.i.d. with

\[
P(s_n = 2) = 1 - P(s_n = 0) = p < \frac{1}{2}.
\]

The process \( \{w_n, n \in \mathbb{Z}\} \) is a discrete time birth-and-death process with stationary distribution

\[
P(w_0 = q) = \left(\frac{p}{1 - p}\right)^q.
\]

We get

\[
\frac{1}{n} \log P(w_0 \geq nq) = -\delta q,
\]

where \( \delta = \log \frac{1 - p}{p} \).

This approximation remains valid under general conditions on the input variables, with an expression of \( \delta \) that depends upon the rate functions associated to the sequences \( a \) and \( s \).

Indeed it has been proved \[2, 8, 13\] that the stationary version of \( w_n \) satisfies the following property

\[
\lim_{n \to \infty} \frac{1}{n} \log P(w_0 > nq) = -\delta q,
\]

or alternatively

\[
P(w_0/n > q) \asymp e^{-n\delta q}.
\]

First we give a heuristic proof of this result which will be asserted rigorously in section 4. We assume the sequences \( \{a_n, n \in \mathbb{Z}\} \) and \( \{s_n, n \in \mathbb{Z}\} \) i.i.d. mutually independent with

\[
\Lambda_A(\theta) = \log \mathbb{E}e^{\theta a_0}, \quad \Lambda_S = \log \mathbb{E}e^{\theta s_0},
\]

finite near the origin. Let \( x_n = s_n - a_n \) for all \( n \in \mathbb{Z} \), and \( X_k = \sum_{i=1}^{k} x_{-i} \) for all \( k \in \mathbb{N} \) then \( w_0 = \sup_{k \geq 0} X_k \), with \( X_0 = 0 \). Using Cramér’s theorem (Theorem 2.4), the sequences \( \{a_n, n \in \mathbb{Z}\} \) and \( \{s_n, n \in \mathbb{Z}\} \) satisfy large deviations principles on \( \mathbb{R} \) with rate function \( I_A \) and \( I_S \) the Legendre transforms of \( \Lambda_A \) and \( \Lambda_S \). Thus the sequence \( \{x_n, n \in \mathbb{Z}\} \) satisfies a large deviations principle with rate function \( I_X \), which is the Legendre transform of \( \Lambda_X(\theta) = \Lambda_S(\theta) + \Lambda_A(-\theta) \), i.e. \( \mathbb{P}(\frac{X_n}{n} > x) \asymp e^{-nI_X(x)} \). Moreover,

\[
P(w_0 \geq nq) = P(\sup_{k \geq 0} X_k \geq nq) = P(\cup_{k \geq 0} \{X_k \geq qn\}) \leq \sum_{k=1}^{\infty} P(X_k \geq qn).
\]

Since \( \mathbb{P}(X_k \geq nq) = \mathbb{P}(\frac{X_k}{k} \geq \frac{nq}{k}) \asymp e^{-kI_X(qn/k)} \), we check that

\[
P(w_0 \geq nq) \asymp \sum_{k=1}^{\infty} e^{-nqI_X(qn/k)} \cdot \frac{1}{k}.
\]

(13)
We conclude using the principle of the largest term, i.e.

$$\sum_{k=1}^{\infty} e^{-nq \frac{I_X(nq/k)}{nq/k}} \approx e^{-qn\delta}$$

where $\delta = \inf_{x>0} \frac{I_X(x)}{x}$ and we get \([12]\). The principle of the largest term translates the fact that rare events occur in the most likely way. Indeed, the dominant term in \([13]\), which gives the explosion of the waiting times in the queueing system (or the overflow of the stock in the storage model), happens following the most probable scenario.

4 Large deviations for the workload process

First, we give the assumptions under which the approximation \([12]\) is fulfilled. For more general assumptions we refer to the paper by Ganesh et al. \([12]\).

Assumptions:

(i) The sequences $\{a_n, n \in \mathbb{Z}\}$ and $\{s_n, n \in \mathbb{Z}\}$ are i.i.d., mutually independent. Their cumulant generating functions are given by

$$\Lambda_A(\theta) = \log \mathbb{E}e^{\theta a_0}, \quad \Lambda_S(\theta) = \log \mathbb{E}e^{\theta s_0}$$

We assume that both $\Lambda_A$ and $\Lambda_S$ are differentiable near the origin.

(ii) The stability condition

$$1/\mu = \Lambda'_S(0) = \mathbb{E}s_0 < \mathbb{E}a_0 = \Lambda'_A(0) = 1/\lambda$$

is satisfied.

Under (i) and (ii), we have

**Proposition 4.1.** The sequence $\{w_0/n, n \in \mathbb{N}^*\}$ satisfies a large deviations principle with good rate function $I_W(q) = \delta q$, i.e. $\lim_{n \to \infty} \frac{1}{n} \log \mathbb{P}(w_0/n \geq q) = -\delta q$, with

$$\delta = \inf_{0<a<s} \frac{I_{A,S}(a,s)}{s-a} = \sup \{\theta : \Lambda_S(\theta) + \Lambda_A(-\theta) \leq 0\}. \quad (14)$$

**Proof.** First we prove \([14]\). Recall that $x_n = s_n - a_n$, $X_n = \sum_{i=1}^{n} x_{i-1}$, and

$$w_0 = \sup_{k \geq 0} X_k.$$

By the independence assumption, we have

$$\Lambda_X(\theta) = \Lambda_S(\theta) + \Lambda_A(-\theta).$$

By direct application of the contraction principle, we check that

$$I_X(x) = \inf_{y>x} \{I_S(y) + I_A(y-x)\}.$$
Let \( \theta \leq \inf_{x \geq 0} I_X(x)/x \) then

\[
\theta \leq \inf_{x \geq 0} I_X(x)/x \quad \Leftrightarrow \quad \theta \leq I_X(x)/x, \forall x \geq 0
\]

\[
\Leftrightarrow \quad \theta x - I_X(x) \leq 0, \forall x \geq 0
\]

\[
\Leftrightarrow \quad \sup_{x \geq 0} \{\theta x - I_X(x)\} \leq 0
\]

\[
\Leftrightarrow \quad \Lambda_X(\theta) \leq 0 .
\]

The last equivalence is due to the fact that \( \mathbb{E}x_0 < 0 \) (stability condition) and the equation (2). We proved that

\[
\inf_{0 < a < s} \frac{I_{A,S}(a, s)}{s - a} = \inf_{x \geq 0} I_X(x)/x = \sup\{\theta : \Lambda_S(\theta) + \Lambda_A(-\theta) \leq 0\} .
\]

**Lower bound:** For \( q > 0 \), we have \( P(w_0 \geq q) \geq P(X_k \geq q) \). Notice that for \( p \geq \frac{q}{\lceil q/p \rceil} \), we have

\[
P(w_0 \geq q) \geq P\left(\frac{1}{\lceil q/p \rceil} X_{\lceil q/p \rceil} \geq p\right).
\]

Since \( \frac{1}{q} \geq \frac{1}{p} \frac{1}{\lceil q/p \rceil} \), we get

\[
\liminf_{q \to \infty} \frac{1}{q} \log P(w_0 \geq q) \geq \frac{1}{p} \liminf_{q \to \infty} \frac{1}{\lceil q/p \rceil} \log P\left(\frac{1}{\lceil q/p \rceil} X_{\lceil q/p \rceil} \geq p\right)
\]

\[
= \frac{1}{p} \liminf_{n \to \infty} \frac{1}{n} \log P\left(\frac{1}{n} X_n \geq p\right) \geq -\frac{1}{p} I_X(p),
\]

for all \( p > 0 \). We conclude that

\[
\liminf_{q \to \infty} \frac{1}{q} \log P(w_0 \geq q) \geq -\inf_{x > 0} I_X(x) = -\inf_{x > 0} \inf_{y > x} \{I_S(y) + I_A(y - x)\}
\]

\[
= -\inf_{0 < a < s} \frac{I_S(a) + I_A(a)}{s - a} .
\]

**Upper bound:** Recall that \( \Lambda_X(\theta) = \Lambda_S(\theta) + \Lambda_A(-\theta) \). By the stability condition, we have

\[
\Lambda_X'(0) = \log \mathbb{E}\left(\frac{s_1}{a_1}\right) < 0 .
\]

Moreover, \( \Lambda_X \) is differentiable near 0 with \( \Lambda_X(0) = 0 \). Thus, there is a constant \( \Theta > 0 \) such that \( \Lambda_X(\Theta) < 0 \) and \( \mathbb{E}e^{\Theta X_n} < \infty \). Applying Chernoff’s bound, we get, for \( n \in \mathbb{N} \)

\[
P(X_n \geq q) \leq e^{-\Theta q \mathbb{E}e^{\Theta X_n}} .
\]

This leads to

\[
\limsup_{q \to \infty} \frac{1}{q} \log P(X_n \geq q) \leq -\Theta .
\]

For \( N \in \mathbb{N} \), we check that

\[
P\left(\max_{0 \leq n \leq N} X_n \geq q\right) \leq N \max_{0 \leq n \leq N} P(X_n \geq q) .
\]

Allowing \( q \) go to infinity,

\[
\limsup_{q \to \infty} \frac{1}{q} \log P\left(\max_{0 \leq n \leq N} X_n \geq q\right) \leq \max_{0 \leq n \leq N} \limsup_{q \to \infty} \frac{1}{q} \log P(X_n \geq q) \leq -\Theta .
\]
We need now to have a bound for large values of \( n \). Applying the union bound, we have
\[
P(\sup_{n>N} X_n \geq q) \leq \sum_{n>N} P(X_n \geq q) \leq e^{-\Theta q} \sum_{n>N} E e^{\Theta X_n}.
\] (15)

Since \( \frac{1}{n} \log E e^{\Theta X_n} = \Lambda_X(\Theta) < 0 \), there is \( 0 < \epsilon < -\Lambda_X(\Theta) \) et \( N_\Theta \in \mathbb{N} \) such that
\[
\forall n > N_\Theta, \quad \frac{1}{n} \log E e^{\Theta X_n} \leq -\epsilon.
\] (16)

Combining (15) and (4), we obtain
\[
P\left(\sup_{n>N_\Theta} X_n > q\right) \leq e^{-\Theta q} \sum_{n>N_\Theta} e^{-\epsilon n} < \frac{e^{-\Theta q}}{1 - e^{-\epsilon}} e^{-(N_\Theta+1)\epsilon}.
\]

To sum up, we derived the following bound
\[
\limsup_{q \to \infty} \frac{1}{q} \log P\left(\sup_{n>N_\Theta} X_n \geq q\right) \leq -\Theta.
\]

Therefore, for \( \Theta > 0 \) such that \( \Lambda_X(\Theta) < 0 \), we have
\[
\limsup_{q \to \infty} \frac{1}{q} \log P\left(\sup_{n \geq 0} X_n \geq q\right) \leq -\Theta.
\]

We conclude using (14).

This result can be interpreted naively in terms of the following approximation
\[
P(\sup_{n} X_n \geq q) \approx \sup_{n} P(X_n \geq q).
\]

This is nothing more than a consequence of the fact that rare events occur in the most likely way. Moreover, using this approximation one can predict the frequency at which the waiting time (or the level of stock) overflows a given threshold. Indeed if (12) is fulfilled, then we represent the graph (in logarithmic scale) of the frequency of exceeding a level \( q \). The above approximation (Proposition 4.1) inspired numerous applications (described by Courcoubetis et al. [3]) of large deviations to the analysis of the statistics of networks of queues.

## 5 Effective bandwidth

The *bandwidth* of a traffic flow has become a classical feature in communication networks literature. We are interested in the notion of *effective bandwidth* introduced by Kelly in [15], which gives an analytical way of describing the properties of a stochastic flow by means of rare events occurring in the network through which it passes.

In practice, the queues and stores we are interested in have finite capacities, i.e. the queue (respectively the store) rejects customers (respectively stock) each time the waiting time (respectively the amount of stock) overpasses a given threshold. In the queueing context, we assume \( \{s_n, n \in \mathbb{Z}\} \) given and we seek the (deterministic) minimal value \( a_p \) of inter-arrival times such that the probability that the waiting times exceeds the threshold is less than a fixed value \( p \). For the storage model, we assume \( \{a_n, n \in \mathbb{Z}\} \) given and we seek the maximal value \( s_p \) of product arriving at the store at each slot of time, such that the store rejects it with a probability less than \( p \). More precisely, we want to identify the arrivals to both models such that
\[
P(w_0 \geq q) \leq p,
\] (17)
for given values of \( q \) and \( p \).
Queue Let $a_n = a, \forall n \in \mathbb{Z}$, i.e. $\Lambda_A(\theta) = a\theta$. If $s$ is i.i.d., then by Proposition 4.1,
\[
\mathbb{P}(w_0 \geq q) \leq e^{-\delta(a)q}
\]
with
\[
\delta(a) = \sup\{\theta : \theta \geq 0 \text{ and } \Lambda_S(\theta) \leq a\theta\}.
\]
The minimal inter-arrival time for the inequality (17) to be fulfilled is given by $a_p$ such that
\[
a_p = \inf\{a : a \geq 0 \text{ et } e^{-\delta(a)q} \leq p\}.
\]
Let $\theta_p = -\frac{\log p}{q}$, then $\delta(a_p) = \theta_p$ and
\[
a_p = \frac{\Lambda_S(\theta_p)}{\theta_p}.
\]
The variable $a_p$ is the effective bandwidth of the queue. For more details we refer to Kelly’s review [14].

Store Let $s_n = s, \forall n \in \mathbb{Z}$, then $\Lambda_S(\theta) = \theta s$ and
\[
\delta(s) = -\inf\{\theta < 0 : \Lambda_A(\theta) \leq s\theta\}.
\]
the inequality (17) is satisfied if no more than $s_p$ amount of stock arrives to the store at each slot with
\[
s_p = \sup\{s \geq 0 : e^{-\delta(s)q} \leq p\}.
\]
The quantity $s_p$ is the effective bandwidth of the store, with
\[
s_p = \frac{\Lambda_A(\theta_p)}{\theta_p}.
\]

We generalize this notion to non-deterministic arrivals by introducing the functions $\alpha_A(\theta)$ and $\alpha_S(\theta)$ given by
\[
\alpha_A(\theta) = \frac{\Lambda_S(\theta)}{\theta}, \quad \alpha_S(\theta) = \frac{\Lambda_A(\theta)}{\theta},
\]
representing the effective bandwidths of the queue and the store, respectively.

6 Principal of large deviations for the output variables

We proved, in section 4, a large deviations principle for the workload process using classical techniques. It is generally hard to apply these techniques to derive large deviations principles for the output variables. In this section, we will apply the contraction principle to this end. Following the outline of the proof of the existence of fixed points for discrete-time queues in [11], we use theoretical results on large deviations for continuous-time processes.

First, we go back to the workload process to illustrate this method. For $n \in \mathbb{N}^*$, we define
\[
A_n = \sum_{i=1}^{n} a_{-i}, \quad S_n = \sum_{i=1}^{n} s_{-i}.
\]
It is obvious that \( w_0 = \sup_{k \geq 0}(S_k - A_k) \).

To apply the contraction principle it is crucial to define an adapted topology under which the workload process is obtained through a continuous mapping of the input variables. Therefore, we define the polygonal approximation in \( n \) of a given sequence \( \{X_k, k \in \mathbb{N}^*\} \) by

\[
{\tilde{X}}_n(t) = \frac{1}{n}X_{\lfloor nt \rfloor} + (t - \frac{\lfloor nt \rfloor}{n})X_{\lfloor nt \rfloor + 1} - X_{\lfloor nt \rfloor}, \quad t \geq 0.
\]

Let \( \tilde{A}_n \) and \( \tilde{S}_n \) the polygonal approximations in \( n \) of the sequences \( \{A_k, k \in \mathbb{N}\} \) and \( \{S_k, k \in \mathbb{N}\} \).

Notice that for \( n \in \mathbb{N}^* \),

\[
\frac{w_0}{n} = \sup_{k \in \mathbb{N}}(S_k - A_k) = \frac{1}{n} \sup_{t \geq 0}(S_{\lfloor nt \rfloor} - A_{\lfloor nt \rfloor}) = \sup_{t > 0}(\tilde{S}_n(t) - \tilde{A}_n(t)).
\]

A function \( x \) is absolutely continuous (on \( \mathbb{R} \)) if for every \( \epsilon > 0 \), there is \( \eta > 0 \) such that for any finitely many disjoint open intervals \( (a_i, b_i), i = 1 \ldots n \), satisfying \( \sum_{i=1}^{n}(b_i - a_i) \leq \eta \), we have \( \sum_{i=1}^{n}(f(b_i) - f(a_i)) \leq \epsilon \). If \( x \) is absolutely continuous, then its derivative \( x' \) exists almost everywhere and we can write

\[
x(v) - x(u) = \int_{u}^{v} x'(t)dt.
\]

For \( \mu > 0 \), we define \( \mathcal{C}_\mu \) (respectively \( \mathcal{A}_\mu \)) the set of continuous functions (respectively absolutely continuous) \( x : \mathbb{R}_+ \rightarrow \mathbb{R} \) with \( x(0) = 0 \) and

\[
\lim_{t \rightarrow +\infty} \frac{x(t)}{t + 1} = \frac{1}{\mu} < \infty,
\]

equipped with the norm

\[
||x|| = \sup_{t \in \mathbb{R}_+} \frac{x(t)}{t + 1}.
\] (18)

We now focus on large deviations on processes in continuous time in \( \mathcal{C}_\mu \).

**Definition 6.1.** A sequence of processes \( \{X_n, n \in \mathbb{N}\} \), where \( X_n \in \mathcal{C}_\mu \) satisfies a functional large deviations principle with linear geodesics, with instantaneous rate function \( I \), if

(i) the function \( I \) is a rate function, with \( I(1/\mu) = 0 \),

(ii) the sequence \( \{X_n, n \in \mathbb{N}\} \) satisfies a large deviations principle \( \mathcal{C}_\mu \) with rate function \( J_X(\phi) \) such that

\[
J_X(\phi) = \begin{cases} 
\int_{0}^{+\infty} I(\phi'(t))dt & \text{if } \phi \in \mathcal{A}_\mu \\
+\infty & \text{otherwise}.
\end{cases}
\]

Dembo and Zajic explored extensions \[4\] of large deviations principles to processes in continuous time under the topology of uniform convergence on compact intervals. However, this topology is not appropriate in the context of queueing systems. We introduce a coarser topology corresponding to the norm \[13\]. The following large deviations principle is due to Ganesh and O’Connell \[10\]. Notice that if \( x = \{x_n, n \in \mathbb{N}\} \) an i.i.d. sequence with mean \( 1/\mu \), then for \( n \in \mathbb{N}^* \), \( \tilde{X}_n \in \mathcal{C}_\mu \), where \( \tilde{X}_n \) is the polygonal approximation in \( n \) of the sequence \( X = \{X_n, n \in \mathbb{N}\} \) with \( X_n = \sum_{i=1}^{n} x_i \).
Let $x = \{x_n, n \in \mathbb{N}\}$ be a sequence of real-valued random variables and $\Lambda_X$ its cumulant generating function, which we suppose differentiable near the origin. Then the sequence of polygonal approximations $\{X_n, n \in \mathbb{N}^+\}$ of $X = \{X_n, n \in \mathbb{N}\}$, where $X_n = \sum_{i=1}^{n} x_i$, satisfies a functional large deviations principle with linear geodesics on $\mathcal{C}_\mu$ equipped with the norm $\|I\|$, with mean $1/\mu = \Lambda_X'(0)$ and instantaneous rate function $I_X$, i.e.

$$J_X(\phi) = \begin{cases} \int_{0}^{+\infty} I_X(\phi'(t)) dt & \text{if } \phi \in A_\mu \\ +\infty & \text{otherwise.} \end{cases}$$

Under (i), the processes $\tilde{A}_n$ and $\tilde{S}_n$ satisfy functional large deviations principles with linear geodesics and instantaneous rate functions $J_A$ and $J_S$ defined by

$$J_A(\phi) = \begin{cases} \int_{0}^{+\infty} I_A(\phi'(t)) dt & \text{if } \phi \in A_\lambda \\ +\infty & \text{otherwise,} \end{cases}$$

with $I_A(x) = \sup_{\theta \in \mathbb{R}} \{\theta x - \Lambda_A(\theta)\}$, the Legendre transform of $\Lambda_A$. We define $I_S$ and $J_S$ in the same way.

We check (see [12]) that $f : \mathcal{C}_\mu \times \mathcal{C}_\lambda \rightarrow \mathbb{R}_+$ defined by

$$f(\phi, \psi) = \sup_{t>0} (\psi(t) - \phi(t)),$$

is continuous on $\mathcal{C}_\mu \times \mathcal{C}_\lambda$ for the topology induced by the norm $\|I\|$. Indeed $f$ is not continuous under the topology of uniform convergence ( [12] Example 5.2).

Applying the contraction principle, we check that $\{w_1/n, n \in \mathbb{Z}\}$ satisfies a large deviations principle on $\mathbb{R}_+$ with rate function

$$I_W(q) = \inf \left\{ \int_{0}^{\infty} I_{A,S}(\phi'(s)) ds \mid (\phi_1, \phi_2) \in A_\lambda \times A_\mu, f(\phi_1, \phi_2) = q \right\}$$

$$= \inf \left\{ \int_{0}^{\infty} I_{A,S}(\phi'(s)) ds \mid (\phi_1, \phi_2) \in A_\lambda \times A_\mu, \sup_{t>0} (\phi_2(t) - \phi_1(t)) = q \right\},$$

where $I_{A,S}(\phi'(s)) = I_A(\phi_1'(s)) + I_S(\phi_2'(s))$. Combining this with Proposition 4.4, we have

**Corollary 6.3.** The solution of the following optimization problem

$$\begin{cases} \text{Minimizing } \int_{0}^{\infty} I_{A,S}(\phi'(s)) ds \text{ pour } \phi = (\phi_1, \phi_2) \in A_\lambda \times A_\mu \\
\text{subject to } \sup_{t>0} (\phi_2(t) - \phi_1(t)) = q \end{cases}$$

is given by $I_W(q) = \delta q$ where $\delta$ is defined in [17].

In the following paragraph, we make use of the same techniques to give large deviations principles for the output variables

$$d_n = a_n + w_{n+1} - w_n + s_{n+1} - s_n, \quad r_n = s_n - w_{n+1} + w_n.$$  \hspace{1cm} (19)

We define $D = \{D_n, n \in \mathbb{N}\}$ and $R = \{R_n, n \in \mathbb{N}\}$ by

$$D_n = \sum_{i=1}^{n} d_{-i}, \quad R_n = \sum_{i=1}^{n} r_{-i}.$$ 

Let $\tilde{D}_n$ and $\tilde{R}_n$ be their polygonal approximations in $n$. Under (i), (ii) and by Loynes’ scheme [16], we check that

$$(\tilde{D}_n, \tilde{R}_n) \in \mathcal{C}_\lambda \times \mathcal{C}_\mu.$$
6.1 Optimization problem

To make the proof as clear as possible, we introduce a new variable

\[ b_n = a_n + w_{n+1} - w_n , \]

which stands, in a queueing context, for the time between instances of beginning of services for customers \( n \) and \( n + 1 \). Let \( B = \{ B_n, n \in \mathbb{N} \} \) defined by \( B_n = \sum_{i=1}^{n} b_i \) and \( \tilde{B}_n \) its polygonal approximation in \( n \) then \( \tilde{B}_n \in \mathcal{C}_\lambda \). Under (i), we have

**Lemma 6.4.** for \( 0 \leq t \leq 1 \) fixed, the sequences \( \{ \tilde{D}_n(t), n \in \mathbb{N}^* \} \) and \( \{ \tilde{B}_n(t), n \in \mathbb{N}^* \} \) are exponentially equivalent.

**Proof.** Let \( \gamma > 0 \),

\[
\mathbb{P}( \sup_{0 \leq t \leq 1} |\tilde{D}_n(t) - \tilde{B}_n(t)| \geq \gamma ) \leq \mathbb{P}( \sup_{0 \leq t \leq n} |s_{-k} - s_0| > n\gamma )
\]

\[
\leq \sum_{k=0}^{n} \mathbb{P}( |s_{-k} - s_0| > n\gamma )
\]

\[
\leq e^{-\gamma \nu n} \sum_{k=0}^{n} \mathbb{E} e^{\gamma |s_{-k} - s_0|} \leq (n + 1)e^{-\gamma \nu n} e^{2\Lambda_S(\gamma)} .
\]

Since \( \lim_{n \to \infty} \log((n + 1)e^{-\gamma \nu n}) = -\infty \) and thanks to assumption (i) \( \Lambda_S(\gamma) < \infty \) for \( \gamma \) close to 0, we are done.

Thus if one of the sequences \( \{ \tilde{D}_n(t), n \in \mathbb{N}^* \} \) and \( \{ \tilde{B}_n(t), n \in \mathbb{N}^* \} \) satisfies a large deviations principle then the other does too and they both have the same rate function. Since the expression of \( \tilde{B}_n \) (in terms of the input variables) is easier than the one of \( \tilde{D}_n \), we concentrate on \( \tilde{B}_n \) and \( \tilde{R}_n \). In fact,

**Lemma 6.5.** The sequences \( \tilde{B}_n(t) \) and \( \tilde{R}_n(t) \) satisfy

\[
\tilde{B}_n(t) = \tilde{A}_n(t) + \sup_{s>0} \{ \tilde{S}_n(s) - \tilde{A}_n(s) \} - \sup_{s>1} \{ (\tilde{S}_n(s) - \tilde{S}_n(t)) - (\tilde{A}_n(s) - \tilde{A}_n(t)) \}
\]

\[
\tilde{R}_n(t) = \tilde{S}_n(t) - \sup_{s>0} \{ \tilde{S}_n(s) - \tilde{A}_n(s) \} + \sup_{s>1} \{ (\tilde{S}_n(s) - \tilde{S}_n(t)) - (\tilde{A}_n(s) - \tilde{A}_n(t)) \}
\]

**Proof.** We check the result for \( \tilde{B}_n(t) \), the proof goes along the same arguments for \( \tilde{R}_n(t) \). Since \( \tilde{B}_n(t) \) is a linear interpolation of \( B_{[nt]} / n \), we will prove the result for \( B_{[nt]} \). First, we check that

\[
B_{[nt]} = A_{[nt]} + w_0 - w_{-[nt]} .
\]

However, we have \( w_0 = \sup_{s>0} \{ \tilde{S}_n(s) - \tilde{A}_n(s) \} \) then

\[
w_{-[nt]} = \sup_{s>1} \{ (\tilde{S}_n(s) - \tilde{S}_n(t)) - (\tilde{A}_n(s) - \tilde{A}_n(t)) \} .
\]
Theorem 6.6. Under assumptions (i) and (ii), the sequence \( \{ (B_n, R_n, w_0/n), n \in \mathbb{N}^* \} \) satisfies a large deviations principle on \( \mathbb{R}^3_+ \) with rate function

\[
J(x_1, x_2, w) = \inf \{ \delta(w - x_1 + x_2) + I_{A,S}(x_2, x_1); \inf_C g(q, \tau, v_1, v_2) \},
\]

where

\[
g(q, \tau, v_1, v_2) = \tau I_{A,S} \left( \frac{x_2 - v_2}{\tau}, \frac{x_2 - v_2 + w}{\tau} \right) + (1 - \tau) I_{A,S} \left( \frac{v_1}{1 - \tau}, \frac{v_2 - q}{1 - \tau} \right) + \delta q,
\]

with \( \delta = \inf_{0 < a < s} \frac{I_{A,S}(a) + I_{A,S}(s)}{s - a} \) and \( C = \{ (q, \tau, v_1, v_2) \mid q \geq 0, 0 \leq \tau \leq 1, x_2 - v_2 + w = x_1 - v_1 + q \} \).

Proof. By Loynes [16] and lemma [5.5] we check that \( \{ \tilde{B}_n, \tilde{R}_n, w_0/n \} = \Phi(\tilde{A}_n, \tilde{S}_n) \) with

\[
\Phi : \mathcal{C}_\lambda \times \mathcal{C}_\mu \to \mathcal{C}_\lambda \times \mathcal{C}_\mu \times \mathbb{R}.
\]

Let \( \Phi = (\Phi_1, \Phi_2, \Phi_3) \) and \( \phi = (\phi_1, \phi_2) \in \mathcal{C}_\lambda \times \mathcal{C}_\mu \), we have

\[
\begin{align*}
\Phi_1(\phi)(t) &= \phi_1(t) + \sup_{s > 0} \{ \phi_2(s) - \phi_1(s) \} - \sup_{s > t} \{ (\phi_2(s) - \phi_2(t)) - (\phi_1(s) - \phi_1(t)) \} \\
\Phi_2(\phi)(t) &= \phi_2(t) - \sup_{s > 0} \{ \phi_2(s) - \phi_1(s) \} + \sup_{s > t} \{ (\phi_2(s) - \phi_2(t)) - (\phi_1(s) - \phi_1(t)) \} \\
\Phi_3(\phi)(t) &= \sup_{s > 0} \{ \phi_2(s) - \phi_1(s) \}.
\end{align*}
\]

Applying the contraction principle, the sequence \( \{ (\tilde{B}_n, \tilde{R}_n, w_0/n), n \in \mathbb{N}^* \} \) satisfies a large deviations principle with rate function

\[
J(\psi_1, \psi_2, w) = \inf \{ \int_0^\infty I_{A,S}(\phi_1(s), \phi_2(s))ds \mid \Phi(\phi_1, \phi_2) = (\psi_1, \psi_2, w) \}.
\]

This variational problem is generally hard to solve, we restrict ourselves to \( t = 1 \). By the law of large numbers, \( \{ (\tilde{B}_n(1), \tilde{R}_n(1)), n \in \mathbb{N}^* \} = \{ (\frac{B_n}{n}, \frac{R_n}{n}), n \in \mathbb{N}^* \} \) converges to the mean values of the output variables, whereas the large deviations principle gives the fluctuations around these values. The sequence \( \{ (\frac{B_n}{n}, \frac{R_n}{n}, w_0/n), n \in \mathbb{N}^* \} \) satisfies a large deviations principle with rate function

\[
J(x_1, x_2, w) = \inf \{ \int_0^\infty I_{A,S}(\phi_1(s), \phi_2(s))ds \mid [\Phi(\phi_1, \phi_2)](1) = (x_1, x_2, w) \}.
\]

We introduce the variables \( q_0 \) and \( q_1 \) given by

\[
\begin{align*}
q_0 &= \sup_{s > 0} \{ \phi_2(s) - \phi_1(s) \} \\
q_1 &= \sup_{s > 1} \{ (\phi_2(s) - \phi_2(1)) - (\phi_1(s) - \phi_1(1)) \}.
\end{align*}
\]

We rewrite (21) as follows

\[
x_1 = \phi_1(1) + q_0 - q_1, \quad x_2 = \phi_2(1) - q_0 + q_1, \quad w = q_0.
\]

To solve this variational problem we condition on the value of \( q_1 \) to be equal to \( q \). By the stability condition \( \lambda < \mu \), we check that \( q \) is finite. Then \( J(x_1, x_2, w) \) is the solution of the following optimization problem

Minimize \( \int_0^1 I_{A,S}(\phi'(s))ds + \int_1^\infty I_{A,S}(\phi'(s))ds \) over \( \phi \in \mathcal{A}_\lambda \times \mathcal{A}_\mu, q \geq 0 \)

subject to \( q_1 = q, \quad x_1 = \phi_1(1) + q_0 - q_1, \quad x_2 = \phi_2(1) - q_0 + q_1, \quad w = q_0 \),
where \( \phi = (\phi_1(s), \phi_2(s)) \) and \( I_{A,S}(\phi'(s)) = I_A(\phi_1'(s)) + I_S(\phi_2'(s)) \).

Using the auxiliary variable \( q \) allows the decomposition of the initial optimization problem into two minimization problems on \( s \in [0,1] \) and \( s > 1 \) coupled through \( q \). More precisely, we suppose the variables \( x_1, x_2 \) and \( w = q_0 \) given, if we fix \( q = q_1 \), then \( \phi_1(1) \) and \( \phi_2(1) \) are fixed. For \( s > 1 \), the only constraint on \( \phi_1 \) and \( \phi_2 \) is \( q_1 = q \). Consequently, the first minimization consists of

Minimizing \( \int_1^\infty I_{A,S}(\phi_1'(s), \phi_2'(s))ds \), subject to \( q_1 = q \).

The second minimization consists of

Minimizing \( \int_0^1 I_{A,S}(\phi_1'(s), \phi_2'(s))ds \)

subject to \( x_1 = \phi_1(1) + q_0 - q_1, \ x_2 = \phi_2(1) - q_0 + q_1, \ w = q_0 \), knowing \( q_1 = q \). In both cases the minimization is for \( \phi \in \mathcal{A}_\lambda \times \mathcal{A}_\mu \).

For the first problem, let \( \psi \in \mathcal{A}_\lambda \times \mathcal{A}_\mu \) with \( \psi_i(s-1) = \phi_i(s) - \phi_i(1), \ s \geq 1, \ i = 1, 2 \). By lemma 6.3, this optimization gives the rate function associated with \( w_0 \) given in Proposition 4.1 and the minimum is \( \delta q \) where \( \delta = \inf_{a<s} \frac{I_{A,S}(a,s)}{s-a} \).

Hence, to determine \( J(x_1, x_2, w) \) it remains to

Minimize \( \int_0^1 I_A(\phi_1'(s)) + I_S(\phi_2'(s))ds + \delta q \), \hspace{1cm} (23)

for \( (\phi_1, \phi_2) \in \mathcal{A}_\lambda \times \mathcal{A}_\mu \) subject to

\[
\begin{align*}
q & \geq 0, \ w = \sup_{s \geq 0} \{ \phi_2(s) - \phi_1(s) \} \\
x_1 & = \phi_1(1) + w - q \\
x_2 & = \phi_2(1) - w + q.
\end{align*}
\]

- Suppose \( \sup_{s \geq 0} \{ \phi_2(s) - \phi_1(s) \} = \sup_{s \geq 1} \{ \phi_2(s) - \phi_1(s) \} \), then \( w = q + \phi_2(1) - \phi_2(1) \), i.e.

\[
x_1 = \phi_2(1), \ x_2 = \phi_1(1), \ q = w - x_1 + x_2.
\]

The optimisation problem (23) is fulfilled by linear functions \( \phi_1 \) and \( \phi_2 \) and we have

\[
\delta(w - x_1 + x_2) + I_A(x_2) + I_S(x_1).
\]

- If \( \phi_2(s) - \phi_1(s) \) reaches its maximum for \( \tau \in [0,1] \) then

\[
\begin{align*}
x_1 & = -q + \phi_1(1) - \phi_1(\tau) + \phi_2(\tau) \\
x_2 & = q + \phi_2(1) - \phi_2(\tau) + \phi_1(\tau).
\end{align*}
\]

We define \( y_i = \frac{\phi_i(\tau)}{\tau}, z_i = \frac{\phi_1(1) - \phi_i(1)}{1-\tau}, \ i = 1, 2 \) and \( \chi \in \mathcal{A}_\lambda \times \mathcal{A}_\mu \),

\[
\chi_i(t) = \begin{cases} 
y_i t & \text{if } t \in [0, \tau] \\
y_i \tau + z_i(t - \tau) & \text{if } t \in [\tau, 1]
\end{cases}
\]

Using the convexity of \( I_A \) and \( I_S \) and Jensen’s inequality, we have

\[
\int_0^1 I_{A,S}(\chi_1'(s), \chi_2'(s))ds \leq \int_0^1 I_{A,S}(\phi_1'(s), \phi_2'(s))ds.
\]
Resolving the above optimization problem, we have

\[ w \times \text{mean } \theta < \lambda < \mu \]

For \( \delta \) to get departures with mean \( x \), let us give an interpretation of this result in a queueing context. Indeed, the most likely ways in independent and for \( t \), precisely when do we have \( (x_1, x_2) \) functions of the input variables. A natural question is when are these functions equal? More specifically, when do we have \( (I_D, I_R) = (I_A, I_S) \)? We start with an example which translates the result stated in [7] in terms of large deviations.

**Example: the M/M/1 queue** Suppose that \( \{a_n, n \in \mathbb{Z}\} \) and \( \{s_n, n \in \mathbb{Z}\} \) are i.i.d. mutually independent and for \( t \geq 0 \),

\[ P(a_0 > t) = e^{-\lambda t}, \quad P(s_0 > t) = e^{-\mu t}. \]

For \( \theta < \lambda < \mu \),

\[ \Lambda_A(\theta) = \log \left( \frac{\lambda}{\lambda - \theta} \right), \quad \Lambda_S(\theta) = \log \left( \frac{\mu}{\mu - \theta} \right). \]

Since \( \delta = \sup\{\theta > 0, \Lambda_S(\theta) + \Lambda_A(-\theta) < 0\} \), we check that \( \delta = \mu - \lambda \). Moreover we have

\[ I_A(a) = \lambda a - \log(\lambda a) - 1, \quad I_S(s) = \mu s - \log(\mu s) - 1. \]

Resolving the above optimization problem, we have

\[ J(x_1, x_2, w) = \lambda x_1 - \log(\lambda x_1) - 1 + \mu x_2 - \log(\mu x_2) - 1 + (\mu - \lambda)w = I_{A,S}(x_1, x_2) + \delta w. \]
6.2 Existence of fixed points

Suppose \( \{a_n, n \in \mathbb{Z}\} \) and \( \{s_n, n \in \mathbb{Z}\} \) i.i.d., mutually independent with means \( 1/\lambda \) and \( 1/\mu \). They satisfy large deviations principles with rate functions \( I_A \) and \( I_S \) differentiable on \( \mathbb{R}_+ \). Let \( \beta > 0 \) such that
\[
I'_S(x) - I'_A(x) = \beta, \quad \forall x \in \mathbb{R}_+. \tag{24}
\]

We can rewrite this relation in the following which will be useful for future analysis
\[
I_A(x) - I_A(y) = I_S(x) - I_S(y) - \beta(x - y), \quad \forall (x, y) \in (\mathbb{R}_+)^2. \tag{25}
\]

Before stating the fixed point result for the Queue/Store operator for the rate functions, we give an interpretation of the relations \((24)\) and \((25)\) in terms of exponential tilting of measures.

**Definition 6.7.** Let \( \beta > 0 \), we say that a measure \( \nu' \) is the \( \beta \)-exponentially-tilted measure of a given measure \( \nu \) if for all \( x \in \mathbb{R} \),
\[
\frac{d\nu'}{d\nu}(x) = e^{\beta x} \int e^{\beta x} d\nu(x), \tag{26}
\]
where \( (d\nu'/d\nu)(x) \) denotes the density of \( \nu' \) with respect to \( \nu \).

**Proposition 6.8.** Suppose \( \{a_n, n \in \mathbb{Z}\} \) and \( \{s_n, n \in \mathbb{Z}\} \) satisfy relation \((24)\) or \((25)\), with marginals \( \nu_A \) and \( \nu_S \). Then \( \nu_A \) is the \( \beta \)-exponentially-tilted function of \( \nu_S \).

**Proof.** Recall that \( I_A(1/\lambda) = 0 \). We check that
\[
\Lambda_A(\theta) = \sup_{x \in \mathbb{R}} [\theta x - I_A(x)] = \sup_{x \in \mathbb{R}} [\theta x - I_S(x) + I_S(1/\lambda) + \beta(x - 1/\lambda)]
\]
\[
= \sup_{x \in \mathbb{R}} [(\theta + \beta)x - I_S(x)] - \frac{\beta}{\lambda} - I_S(1/\lambda)
\]
\[
= \Lambda_S(\theta + \beta) - \Lambda_S(\beta). \tag{27}
\]

Considering the exponentials on both sides, we have
\[
\int_{\mathbb{R}_+} e^{\theta x} d\nu_A(x) = \frac{\int_{\mathbb{R}_+} e^{(\theta + \beta)x} d\nu_S(x)}{\int_{\mathbb{R}_+} e^{\beta x} d\nu_S(x)}. \tag{28}
\]

**Lemma 6.9.** Assume that \( \{a_n, n \in \mathbb{Z}\} \) and \( \{s_n, n \in \mathbb{Z}\} \) satisfy assumptions (i) and (ii). Then the tilt coefficient \( \beta \) is given by
\[
\beta = \sup \{\theta : \Lambda_S(\theta) + \Lambda_A(-\theta) \leq 0\}. \tag{29}
\]
Proof. Let $\theta = -\beta$ in (27), we have

$$\Lambda_A(-\beta) = \Lambda_S(0) - \Lambda_S(\beta).$$

Since $\Lambda_S(0) = 0$, we obtain $\Lambda_A(-\beta) + \Lambda_S(\beta) = 0$. Thanks to (14), we have

$$\beta \leq \sup\{\theta \geq 0, \Lambda_S(\theta) + \Lambda_A(-\theta) \leq 0\} = \delta.$$

The function $G(\theta) = \Lambda_S(\theta) + \Lambda_A(-\theta)$ is convex with $G(0) = 0$. Moreover, by assumption (ii),

$$G'(0) = \Lambda_S'(0) - \Lambda_A'(0) < 0.$$

This means that $G$ is equal to zero twice on $[0, \beta]$, at 0 and $\beta$, then

$$\beta = \sup\{\theta \geq 0, \Lambda_S(\theta) + \Lambda_A(-\theta) \leq 0\} = \delta.$$

\[\square\]

**Theorem 6.10.** Let $\delta > 0$ and the sequences $\{a_n, n \in \mathbb{Z}\}$ and $\{s_n, n \in \mathbb{Z}\}$ the input variables of the model with $\nu_A$ the $\delta$-tilted measure of $\nu_S$ (or $\nu_S$ the $(-\delta)$-tilted measure of $\nu_A$). Then the sequence $\{(\frac{P_n}{n}, \frac{R_n}{n}, w_0/n), n \in \mathbb{Z}^*\}$ satisfies a large deviations principle on $\mathbb{R}_+^3$ with rate function

$$J(x_1, x_2, w) = \delta w + I_{A,S}(x_1, x_2). \quad (28)$$

Moreover, we have

$$I_D = I_A \quad \text{and} \quad I_R = I_S.$$

**Proof.** By Theorem 6.6 the sequence $\{(\tilde{D}_n(1), \tilde{R}_n(1), w_1/n), n \in \mathbb{N}^*\}$ satisfies a large deviations principle on $\mathbb{R}_+^3$ with rate function

$$J(x_1, x_2, w) = \inf\{\delta(w - x_1 + x_2) + I_{A,S}(x_2, x_1); \inf_C g(q, \tau, v_1, v_2)\},$$

We start with the first term of this optimization problem, i.e.

$$x_1 = \phi_2(1), \quad x_2 = \phi_2(1) \quad q = w - x_1 + x_2.$$

We have $w = x_1 - x_2 + q$, and thanks to (25),

$$\delta(w - x_1 + x_2) + I_{A,S}(x_2, x_1) = \delta(w - x_1 + x_2) + I_{A,S}(x_1, x_2) + \delta(x_1 - x_2) = \delta w + I_{A,S}(x_1, x_2).$$

For the second term, let $(q, \tau, v_1, v_2) \in C$,

- If $v_1 = v_2$, from the convexity property, then

$$g(q, \tau, v_1, v_2) = \delta q + \tau I_{A,S}(\frac{x_2 - v_2}{\tau}, \frac{x_2 - v_2 + w}{\tau}) + (1 - \tau) I_{A,S}(\frac{v_2}{1 - \tau}, \frac{v_2 - q}{1 - \tau}) \geq \delta q + I_{A,S}(x_2, x_2 + w - q) = \delta w + I_{A,S}(x_1, x_2).$$
\begin{itemize}
  \item If \( v_1 > v_2 \), then
  \[
  I_{A,S} \left( \frac{x_2 - v_2}{\tau}, \frac{x_2 - v_2 + w}{\tau} \right) = I_{A,S} \left( \frac{x_2 - v_2 + w}{\tau}, \frac{x_2 - v_2}{\tau} \right) + \frac{w}{\tau}
  \]

  Notice that
  \[
  I_S \left( \frac{v_2 - q}{1 - \tau} \right) = I_S \left( \frac{v_2}{1 - \tau} \right) + I_A \left( \frac{v_2 - q}{1 - \tau} \right) - I_A \left( \frac{v_2}{1 - \tau} \right) - \frac{q}{1 - \tau}.
  \]

  Since \( I_A \) is convex and \( v_1 \geq v_2 \), we have
  \[
  I_A \left( \frac{v_2 - q}{1 - \tau} \right) - I_A \left( \frac{v_2}{1 - \tau} \right) \geq I_A \left( \frac{v_1 - q}{1 - \tau} \right) - I_A \left( \frac{v_1}{1 - \tau} \right).
  \]

  Thus,
  \[
  I_S \left( \frac{v_2 - q}{1 - \tau} \right) + I_A \left( \frac{v_1 - q}{1 - \tau} \right) \geq I_S \left( \frac{v_2}{1 - \tau} \right) + I_A \left( \frac{v_2 - q}{1 - \tau} \right) - \frac{q}{1 - \tau}.
  \]

  Since \( I_A \) and \( I_S \) are convex and \( x_2 - v_2 + w + v_1 - q = x_1 \), we have
  \[
  g(q) \geq \delta w + I_{A,S}(x_1, x_2).
  \]

  We conclude that \( J(x_1, x_2, w) = \delta w + I_{A,S}(x_1, x_2) \).
\end{itemize}

In other words, the above theorem states that if the input variables satisfy large deviations principles with rate functions \( I_A \) and \( I_S \) with \( \nu_A \) the \( \delta \)-tilted measure of \( \nu_S \), then the output variables satisfy large deviations principles with the same rate functions.
