Abstract. We show that, for both the conformal and projective groups, all the differential invariants of a generic surface in three-dimensional space can be written as combinations of the invariant derivatives of a single differential invariant. The proof is based on the equivariant method of moving frames.

Key words: conformal differential geometry; projective differential geometry; differential invariants; moving frame; syzygy; differential algebra

1 Introduction

According to Cartan, the local geometry of submanifolds under transformation groups, including equivalence and symmetry properties, are entirely governed by their differential invariants. Familiar examples are curvature and torsion of a curve in three-dimensional Euclidean space, and the Gauss and mean curvatures of a surface, [11, 30, 37].

In general, given a Lie group $G$ acting on a manifold $M$, we are interested in studying its induced action on submanifolds $S \subset M$ of a prescribed dimension, say $p < m = \dim M$. To this end, we prolong the group action to the submanifold jet bundles $J^n = J^n(M, p)$ of order $n \geq 0$, [30]. A differential invariant is a (perhaps locally defined) real-valued function $I: J^n \to \mathbb{R}$ that is invariant under the prolonged group action. Any finite-dimensional Lie group action admits an infinite number of functionally independent differential invariants of progressively higher and higher order. Moreover, there always exist $p = \dim S$ linearly independent invariant differential operators $\mathcal{D}_1, \ldots, \mathcal{D}_p$. For curves, the invariant differentiation is with respect to the group-invariant arc length parameter; for Euclidean surfaces, with respect to the diagonalizing Frenet frame, [11, 22, 24, 25, 26]. The Fundamental Basis Theorem, first formulated by Lie, [23, p. 760], states that all the differential invariants can be generated from a finite number of low order invariants by repeated invariant differentiation. A modern statement and proof of Lie’s Theorem can be found, for instance, in [30].

A basic question, then, is to find a minimal set of generating differential invariants. For curves, where $p = 1$, the answer is known: under mild restrictions on the group action (specifically transitivity and no pseudo-stabilization under prolongation), there are exactly $m - 1$
generating differential invariants, and any other differential invariant is a function of the generating invariants and their successive derivatives with respect to arc length [30]. Thus, for instance, the differential invariants of a space curve $C \subset \mathbb{R}^3$ under the action of the Euclidean group $SE(3)$, are generated by $m-1 = 2$ differential invariants, namely its curvature and torsion.

In [34], it was proved, surprisingly that, for generic surfaces in three-dimensional space under the action of either the Euclidean or equi-affine (volume-preserving affine) groups, a minimal system of generating differential invariants consists of a single differential invariant. In the Euclidean case, the mean curvature serves as a generator of the Euclidean differential invariants under invariant differentiation. In particular, an explicit, apparently new formula expressing the Gauss curvature as a rational function of derivatives of the mean curvature with respect to the Frenet frame was found. In the equi-affine case, there is a single third order differential invariant, known as the Pick invariant, [36, 37], which was shown to generate all the equi-affine differential invariants through invariant differentiation.

In this paper, we extend this research program to study the differential invariants of surfaces in $\mathbb{R}^3$ under the action of the conformal and the projective groups. Tresse classified the differential invariants in both cases in 1894, [38]. Subsequent developments in conformal geometry can be found in [2, 3, 7, 39], as well as the work of Tom Branson and collaborators surveyed in the papers in this special issue, while [1, 8, 27] present results on the projective geometry of submanifolds.

The goal of this note is to prove that, just as in the Euclidean and equi-affine cases, the differential invariants of both actions are generated by a single differential invariant though invariant differentiation with respect to the induced Frenet frame. However, lest one be tempted to naïvely generalize these results, [33] gives examples of finite-dimensional Lie groups acting on surfaces in $\mathbb{R}^3$ which require an arbitrarily large number of generating differential invariants. Our two main results are:

**Theorem 1.** Every differential invariant of a generic surface $S \subset \mathbb{R}^3$ under the action of the conformal group $SO(4,1)$ can be written in terms of a single third order invariant and its invariant derivatives.

**Theorem 2.** Every differential invariant of a generic surface $S \subset \mathbb{R}^3$ under the action of the projective group $PSL(4)$ can be written in terms of a single fourth order invariant and its invariant derivatives.

The proofs follow the methods developed in [34]. They are based on [6], where moving frames were introduced as equivariant maps from the manifold to the group. A recent survey of the many developments and applications this approach has entailed can be found in [32]. Further extensions are in [18, 19, 16, 17, 33].

A moving frame induces an invariantization process that maps differential functions and differential operators to differential invariants and (non-commuting) invariant differential operators. Normalized differential invariants are the invariantizations of the standard jet coordinates and are shown to generate differential invariants at each order: any differential invariant can be written as a function of the normalized invariants. This rewriting is actually a trivial replacement.

The key to the explicit, finite description of differential invariants of any order lies in the recurrence formulae that explicitly relate the differentiated and normalized differential invariants. Those formulae show that any differential invariant can be written in terms of a finite set of normalized differential invariants and their invariant derivatives. Combined with the replacement rule, the formulae make the rewriting process effective. Remarkably, these fundamental relations can be constructed using only the (prolonged) infinitesimal generators of the group action and the moving frame normalization equations. One does not need to know the explicit formulas for
either the group action, or the moving frame, or even the differential invariants and invariant differential operators, in order to completely characterize generating sets of differential invariants and their syzygies. Moreover the syzygies and recurrence relations are given by rational functions and are thus amenable to algebraic algorithms and symbolic software [13, 14, 15, 19] that we have used for this paper.

2 Moving frames and differential invariants

In this section we review the construction of differential invariants and invariant derivations proposed in [6]; see also [19, 16, 33, 34]. Let $G$ be an $r$-dimensional Lie group that acts (locally) on an $m$-dimensional manifold $M$. We are interested in the action of $G$ on $p$-dimensional submanifolds $N \subset M$ which, in local coordinates, we identify with the graphs of functions $u = f(x)$. For each positive integer $n$, let $G^{(n)}$ denote the prolonged group action on the associated $n$-th order submanifold jet space $J^n = J^n(M, p)$, defined as the set of equivalence classes of $p$-dimensional submanifolds of $M$ under the equivalence relation of $n$-th order contact. Local coordinates on $J^n$ are denoted $z^{(n)} = (x, u^{(n)}) = (\ldots x^i \ldots u^a_j \ldots)$, with $u^a_j$ representing the partial derivatives of the dependent variables $u = (u^1, \ldots, u^q)$ with respect to the independent variables $x = (x^1, \ldots, x^p)$, where $p + q = m$ [30].

Assuming that the prolonged action is free on an open subset of $J^n$, then one can construct a (locally defined) moving frame, which, according to [6], is an equivariant map $\rho: V^n \to G$ defined on an open subset $V^n \subset J^n$. Equivariance can be with respect to either the right or left multiplication action of $G$ on itself. All classical moving frames, e.g., those appearing in [5, 9, 10, 11, 20, 21], can be regarded as left equivariant maps, but the right equivariant versions may be easier to compute, and will be the version used here. Of course, any right moving frame can be converted to a left moving frame by composition with the inversion map $g \mapsto g^{-1}$.

In practice, one constructs a moving frame by the process of normalization, relying on the choice of a local cross-section $K^n \subset J^n$ to the prolonged group orbits, meaning a submanifold of the complementary dimension that intersects each orbit transversally. A general cross-section is prescribed implicitly by setting $r = \dim G$ differential functions $Z = (Z_1, \ldots, Z_r)$ to constants:

$$Z_1(x, u^{(n)}) = c_1, \ldots, Z_r(x, u^{(n)}) = c_r. \quad (2.1)$$

Usually – but not always, [28, 34] – the functions are selected from the jet space coordinates $x^i$, $u^a_j$, resulting in a coordinate cross-section. The corresponding value of the right moving frame at a jet $z^{(n)} \in J^n$ is the unique group element $g = \rho^{(n)}(z^{(n)}) \in G$ that maps it to the cross-section:

$$\rho^{(n)}(z^{(n)}) \cdot z^{(n)} = g^{(n)} \cdot z^{(n)} \in K^n. \quad (2.2)$$

The moving frame $\rho^{(n)}$ clearly depends on the choice of cross-section, which is usually designed so as to simplify the required computations as much as possible.

Once the cross-section has been fixed, the induced moving frame engenders an invariantization process, that effectively maps functions to invariants, differential forms to invariant differential forms, and so on. [6, 32]. Geometrically, the invariantization of any object is defined as the unique invariant object that coincides with its progenitor when restricted to the cross-section. In the special case of functions, invariantization is actually entirely defined by the cross-section, and therefore doesn’t require the action to be (locally) free. It is a projection from

\footnote{A theorem of Ovsiannikov, [35], slightly corrected in [31], guarantees local freeness of the prolonged action at sufficiently high order, provided $G$ acts locally effectively on subsets of $M$. This is only a technical restriction; for example, all analytic actions can be made effective by dividing by the global isotropy subgroup. Although all known examples of prolonged effective group actions are, in fact, free on an open subset of a sufficiently high order jet space, there is, frustratingly, as yet no general proof, nor known counterexample, to this result.}
the ring of differential functions to the ring of differential invariants, the latter being isomorphic to the ring of smooth functions on the cross-section \([19]\).

Pragmatically, the invariantization of a differential function is constructed by first writing out how it is transformed by the prolonged group action: \(F(z^{(n)}) \mapsto F(g^{(n)} \cdot z^{(n)})\). One then replaces all the group parameters by their right moving frame formulae \(g = \rho^{(n)}(z^{(n)})\), resulting in the differential invariant
\[
\iota[F(z^{(n)})] = F(\rho^{(n)}(z^{(n)}) \cdot z^{(n)}).
\]

Differential forms and differential operators are handled in an analogous fashion – see \([6, 22]\) for complete details. Alternatively, the algebraic construction for the invariantization of functions in \([19]\) works with the knowledge of the cross-section only, i.e. without the explicit formulae for the moving frame, and applies to non-free actions as well.

In particular, the normalized differential invariants induced by the moving frame are obtained by invariantization of the basic jet coordinates:
\[
H^i = \iota(x^i), \quad I^a_j = \iota(u^a_J),
\]
which we collectively denote by \((H, I^{(n)}) = (\ldots H^i \ldots I^a_j \ldots)\) for \(#J \leq n\). In the case of a coordinate cross-section, these naturally split into two classes: Those corresponding to the cross-section functions \(Z_\kappa\) are constant, and known as the phantom differential invariants. The remainder, known as the basic differential invariants, form a complete system of functionally independent differential invariants.

Once the normalized differential invariants are known, the invariantization process \((2.3)\) is implemented by simply replacing each jet coordinate by the corresponding normalized differential invariant \((2.4)\), so that
\[
\iota[F(x, u^{(n)})] = F(\ldots x^i \ldots u^a_J \ldots) = F(H, I^{(n)}).
\]

In particular, a differential invariant is not affected by invariantization, leading to the very useful Replacement Theorem:
\[
J(x, u^{(n)}) = J(H, I^{(n)}) \quad \text{whenever } J \text{ is a differential invariant.}
\]

This permits one to straightforwardly rewrite any known differential invariant in terms the normalized invariants, and thereby establishes their completeness.

A contact-invariant coframe is obtained by taking the horizontal part (i.e., deleting any contact forms) of the invariantization of the basic horizontal one-forms:
\[
\omega^i \equiv \iota(dx^i) \quad \text{modulo contact forms,} \quad i = 1, \ldots, p,
\]

Invariant differential operators \(\mathcal{D}_1, \ldots, \mathcal{D}_p\) can then be defined as the associated dual differential operators, defined so that
\[
dF \equiv \sum_{i=1}^{p} (\mathcal{D}_i F) \omega^i \quad \text{modulo contact forms,}
\]
for any differential function \(F\). Details can be found in \([6, 22]\). The invariant differential operators do not commute in general, but are subject to the commutation formulae
\[
[\mathcal{D}_j, \mathcal{D}_k] = \sum_{i=1}^{p} Y^i_{jk} \mathcal{D}_i,
\]
where the coefficients \(Y^i_{jk} = -Y^i_{kj}\) are certain differential invariants known as the commutator invariants.
3 Recurrence and syzygies

In general, invariantization and differentiation do not commute. By a recurrence relation, we mean an equation expressing an invariantly differentiated invariant in terms of the basic differential invariants. Remarkably, the recurrence relations can be deduced knowing only the (prolonged) infinitesimal generators of the group action and the choice of cross-section.

Let \( v_1, \ldots, v_r \) be a basis for the infinitesimal generators of our transformation group. We prolong each infinitesimal generator to \( J^n \), resulting in the vector fields

\[
v^{(n)}_\kappa = \sum_{i=1}^p \xi_i^{(n)}(x,u) \frac{\partial}{\partial x^i} + \sum_{\alpha=1}^q \sum_{j=0}^n \varphi_{J,\kappa}^{(n)}(x,u^{(j)}) \frac{\partial}{\partial u^{(j)}_\alpha}, \quad \kappa = 1, \ldots, r,
\]

on \( J^n \). The coefficients \( \varphi_{J,\kappa}^{(n)} = v^{(n)}_\kappa(u^{(j)}) \) are given by the prolongation formula. \[29, 30\]:

\[
\varphi_{J,\kappa}^{(n)} = D_j \left( \varphi_{\kappa}^{(n)} - \sum_{i=1}^p \xi_i \varphi_{\kappa}^{(n)} \right) + \sum_{i=1}^p \xi_i u^{(j)}_i,
\]

where \( D_1, \ldots, D_p \) are the usual (commuting) total derivative operators, and \( D_j = D_{j_1} \cdots D_{j_k} \) the corresponding iterated total derivative.

Given a collection \( F = (F_1, \ldots, F_k) \) of differential functions, let

\[
v(F) = (v^{(n)}_\kappa(F_j)) \quad (3.3)
\]

 denote the \( r \times k \) generalized Lie matrix obtained by applying the prolonged infinitesimal generators to the differential functions. In particular, \( L^{(n)}(x,u^{(n)}) = v(x,u^{(n)}) \) is the classical Lie matrix of order \( n \) whose entries are the infinitesimal generator coefficients \( \xi_{\kappa}, \varphi_{J,\kappa}^{(n)} \). \[30, 33\]. The rank of the classical Lie matrix \( L^{(n)}(x,u^{(n)}) \) equals the dimension of the prolonged group orbit passing through the point \( (x,u^{(n)}) \in J^n \). We set

\[
\begin{align*}
    r_n = & \max \{ \text{rank } L^{(n)}(x,u^{(n)}) \mid (x,u^{(n)}) \in J^n \} \\ & (3.4)
\end{align*}
\]

to be the maximal prolonged orbit dimension. Clearly, \( r_0 \leq r_1 \leq r_2 \leq \cdots \leq r = \dim G \), and \( r_n = r \) if and only if the action is locally free on an open subset of \( J^n \). Assuming \( G \) acts locally effectively on subsets, \[31\], this holds for \( n \) sufficiently large. We define the stabilization order \( s \) to be the minimal \( n \) such that \( r_n = r \). Locally, the number of functionally independent differential invariants of order \( \leq n \) equals \( \dim J^n - r_n \).

The fundamental moving frame recurrence formulae were first established in \[6\] and written as follows; see also \[33\] for additional details.

**Theorem 3.** The recurrence formulae for the normalized differential invariants have the form

\[
\begin{align*}
    D_i H^j &= \delta^i_j + \sum_{\kappa=1}^r R^\kappa_i \iota(\xi^\kappa_j), \\
    D_i I^\alpha_j &= I^\alpha_j + \sum_{\kappa=1}^r R^\kappa_i \iota(\varphi_{\kappa,j}^{\alpha}),
\end{align*}
\]

where \( \delta^i_j \) is the usual Kronecker delta, and \( R^\kappa_i \) are certain differential invariants. \[3,5\]

The recurrence formulae imply the following commutator syzygies among the normalized differential invariants:

\[
\begin{align*}
    D_i I^\alpha_{j} - D_j I^\alpha_{i} &= \sum_{\kappa=1}^r \left[ R^\kappa_i \iota(\varphi_{\kappa,j}^{\alpha}) - R^\kappa_j \iota(\varphi_{\kappa,i}^{\alpha}) \right], \quad (3.6)
\end{align*}
\]
for all $1 \leq i, j \leq p$ and all multi-indices $J$. We can show that a subset of these relationships (3.5), (3.6) form a complete set of syzygies, [16]. By formally manipulating those syzygies, performing differential elimination [4, 12, 13, 14], we are able to obtain expressions of some of the differential invariants in terms of the invariant derivatives of others. This is the strategy for the main results of this paper.

In the case of coordinate cross-section, if we single out the recurrence formulae for the constant phantom differential invariants prescribed by the cross-section, the left hand sides are all zero, and hence we obtain a linear algebraic system that can be uniquely solved for the invariants $R^\kappa_i$. Substituting the resulting formulae back into the recurrence formulae for the remaining, non-constant basic differential invariants leads to a complete system of relations among the normalized differential invariants [6, 33].

More generally, if we think of the $R^\kappa_i$ as the entries of a $p \times r$ matrix

$$R = (R^\kappa_i),$$

then they are given explicitly by

$$R = -\iota[D(Z) \nu(Z)^{-1}],$$

where $Z = (Z_1, \ldots, Z_r)$ are the cross-section functions (2.1), while

$$D(Z) = (D_i Z_j)$$

is the $p \times r$ matrix of their total derivatives. The recurrence formulae are then covered by the matricial equation [16]

$$\mathcal{D}(\iota(F)) = \iota(D(F)) + R \iota(\nu(F)),$$

for any set of differential functions $F = (F_1, \ldots, F_k)$. The left hand side denotes the $p \times k$ matrix

$$\mathcal{D}(\iota(F)) = (\mathcal{D}_i(\iota(F_j)))$$

obtained by invariant differentiation.

The invariants $R^\kappa_i$ actually arise in the proof of (3.5) as the coefficients of the horizontal parts of the pull-back of the Maurer–Cartan forms via the moving frame, [6]. Explicitly, if $\mu^1, \ldots, \mu^r$ are a basis for the Maurer–Cartan forms on $G$ dual to the Lie algebra basis $v_1, \ldots, v_r$, then the horizontal part of their pull-back by the moving frame can be expressed in terms of the contact-invariant coframe (2.1):

$$\gamma^\kappa = \rho^* \mu^\kappa \equiv \sum_{i=1}^p R^\kappa_i \omega^i \mod \text{contact forms.}$$

We shall therefore refer to $R^\kappa_i$ as the Maurer–Cartan invariants, while $R$ in (3.7) will be called the Maurer–Cartan matrix. In the case of curves, when $G \subset \mathrm{GL}(N)$ is a matrix Lie group, the Maurer–Cartan matrix $R = \mathcal{D}\rho^{(n)}(x, u^{(n)}) \cdot \rho^{(n)}(x, u^{(n)})^{-1}$ can be identified with the Frenet–Serret matrix, [11, 26], with $\mathcal{D}$ the invariant arc-length derivative.

The identification (3.12) of the Maurer–Cartan invariants as the coefficients of the (horizontal parts of) the pulled-back Maurer–Cartan forms can be used to deduce their syzygies, [17]. The Maurer–Cartan forms on $G$ satisfy the usual Lie group structure equations

$$d\mu^c = - \sum_{a<b} C^c_{ab} \mu^a \wedge \mu^b, \quad c = 1, \ldots, r,$$

(3.13)
where \( C_{ab}^c \) are the structure constants of the Lie algebra relative to the basis \( v_1, \ldots, v_r \). It follows that their pull-backs \( (3.12) \) satisfy the same equations:
\[
d\gamma^c = - \sum_{a<b} C_{ab}^c \gamma^a \wedge \gamma^b, \quad c = 1, \ldots, r.
\] (3.14)

The purely horizontal components of these identities provide the following syzygies among the Maurer–Cartan invariants, \([17]\):

**Theorem 4.** The Maurer–Cartan invariants satisfy the following identities:
\[
D_j(R_i^c) - D_i(R_j^c) + \sum_{1 \leq a < b \leq r} C_{ab}^c (R_a^i R_b^j - R_b^i R_a^j) + \sum_{k=1}^p Y_{jk}^i R_k^c = 0,
\] (3.15)

for \( 1 \leq c \leq r, 1 \leq i < j \leq p \), and where \( Y_{jk}^i \) are the commutator invariants \([28]\).

Finally, we note the recurrence formulas for the invariant differential forms established in \([6]\) produce the explicit formulas for the commutator invariants:
\[
Y_{jk}^i = \sum_{\kappa=1}^r \sum_{j=1}^p R_j^\kappa t(D_j \xi^i_k) - R_k^\kappa t(D_k \xi^j_i).
\] (3.16)

## 4 Generating differential invariants

A set of differential invariants \( \mathcal{I} = \{ I_1, \ldots, I_k \} \) is called *generating* if, locally, every differential invariant can be expressed as a function of them and their iterated invariant derivatives \( D_J I_\nu \). A key issue is to find a minimal set of generating invariants, which (except for curves) must be done on a case by case basis. Before investigating the minimality question in the conformal and projective examples, let us state general results characterizing (usually non-minimal) generating systems. These results are all consequences of the recurrence formulae, \((3.5)\) or \((3.10)\), that furthermore make the rewriting constructive.

Let
\[
\mathcal{J}^n = \{ H^1, \ldots, H^p \} \cup \{ I_j^\alpha \mid \alpha = 1, \ldots, q, \#J \leq n \}
\] (4.1)
de note the complete set of normalized differential invariants of order \( \leq n \). In particular, assuming we choose a cross-section that projects to a cross-section on \( M \) (e.g., a minimal order cross-section) then \( \mathcal{J}^0 = \{ H^1, \ldots, H^p, I^1, \ldots, I^q \} \) are the ordinary invariants for the action on \( M \). In particular, if, as in the examples treated here, the action is transitive on \( M \), the normalized order 0 invariants are all constant, and hence are superfluous for the following generating systems.

**Theorem 5.** If the moving frame has order \( n \), then the set of normalized differential invariants \( \mathcal{J}^{n+1} \) of order \( n + 1 \) or less forms a generating set.

For cross-section of *minimal order* there is an additional important set of invariants that is generating. This was proved for coordinate cross-sections in \([33]\) and then generalized in \([16]\). For each \( k \geq 0 \), let \( r_k \) denote the maximal orbit dimension of the action of \( G^{(k)} \) on \( J^k \).

**Theorem 6.** Let \( Z = (Z_1, \ldots, Z_r) \) define a minimal order cross-section in the sense that for each \( k = 0, 1, \ldots, s \), where \( s \) is the stabilization order, \( Z_k = (Z_1, \ldots, Z_{r_k}) \) defines a cross-section for the action of \( G^{(k)} \) on \( J^k \). Then \( \mathcal{J}^0 \cup \mathcal{Z} \), where
\[
\mathcal{Z} = \{ t(D_i(Z_j)) \mid 1 \leq i \leq p, 1 \leq j \leq r \},
\] (4.2)
form a generating set of differential invariants.
Another interesting consequence of Theorem 3 observed in [17] is that the Maurer–Cartan invariants
\[ \mathfrak{R} = \{ R_i^a \mid 1 \leq i \leq p, 1 \leq a \leq r \} \quad (4.3) \]
also form a generating set when the action is transitive on \( M \). More precisely:

**Theorem 7.** The differential invariants \( \mathfrak{I}^0 \cup \mathfrak{R} \) form a generating set.

In [34], the following device for generating the commutator invariants was introduced, and then applied to the differential invariants of Euclidean and equi-affine surfaces. We will employ the same trick here.

**Theorem 8.** Let \( I = (I_1, \ldots, I_p) \) be a set of differential invariants such that \( D(I) \), cf. (3.11), forms a nonsingular \( p \times p \) matrix of differentiated invariants. Then one can express the commutator invariants as rational functions of the invariant derivatives, of order \( \leq 2 \), of \( I_1, \ldots, I_p \).

**Proof.** In view of (2.8), we have
\[ D_i D_j I_l - D_j D_i I_l = \sum_{k=1}^{p} Y_{jk}^i D_k I_l. \quad (4.4) \]
We regard (4.4) as a system of \( p \) linear equations for the commutator invariants \( Y_{jk}^i \). Our assumption implies that the coefficient matrix is nonsingular. Solving the linear system by, say, Cramer’s rule, produces the formulae for the \( Y_{jk}^i \). ■

In particular, if \( I \) is any single differential invariant with sufficiently many nontrivial invariant derivatives, the differential invariants in the proposition can be taken as invariant derivatives of \( I \). Typically we choose \( I \) of order at least \( n \), the order of the moving frame, and \( p - 1 \) of its first order invariant derivatives. If \( I \) is a basic invariant, nonsingularity of the matrix of differentiated invariants is then a consequence of the recurrence formulæ. As a result, one is, in fact, able to generate all of the commutator invariants as combinations of derivatives of a single differential invariant!

5 Differential invariants of surfaces

Let us specialize the preceding general constructions to the case of two-dimensional surfaces in three-dimensional space. Let \( G \) be a \( r \)-dimensional Lie group acting transitively and effectively on \( M = \mathbb{R}^3 \). Let \( J^n = J^n(\mathbb{R}^3, 2) \) denote the \( n \)-th order surface jet bundle, with the usual induced coordinates \( z^{(n)} = (x, y, u, u_x, u_y, u_{xx}, \ldots, u_{jk}, \ldots) \) for \( j + k \leq n \).

Let \( n \geq s \), the stabilization order of \( G \). Given a cross-section \( K^n \subset J^n \), let \( \rho : V^n \to G \) be the induced right moving frame defined on a suitable open subset \( V^n \subset J^n \) containing \( K^n \). Invariantization of the basic jet coordinates results in the normalized differential invariants
\[ H_1 = \iota(x), \quad H_2 = \iota(y), \quad I_{jk} = \iota(u_{jk}), \quad j, k \geq 0. \quad (5.1) \]
In view of our transitivity assumption, we will only consider cross-sections that normalize the order 0 variables, \( x = y = u = 0 \), and so the order 0 normalized invariants are trivial: \( H_1 = H_2 = I_{00} = 0 \). We use
\[ I^{(n)} = (0, I_{01}, I_{02}, I_{10}, I_{11}, \ldots, I_{0n}) = \iota(u^{(n)}) \quad (5.2) \]
to denote all the normalized differential invariants, both phantom and basic, of order \( \leq n \) obtained by invariantizing the dependent variable \( u \) and its derivatives.
In addition, the two invariant differential operators $D_1, D_2$, are obtained as the total derivations dual to the contact-invariant coframe determined by the moving frame: Specializing the general moving frame recurrence formulae in Theorem 3, we have:

**Theorem 9.** The recurrence formulae for the differentiated invariants are

\[ D_1 I_{jk} = I_{j+1,k} + \sum_{\kappa=1}^{r} \varphi_{\kappa}^{jk}(0, 0, I^{(j+k)}) R_{1}^\kappa, \]

\[ D_2 I_{jk} = I_{j,k+1} + \sum_{\kappa=1}^{r} \varphi_{\kappa}^{jk}(0, 0, I^{(j+k)}) R_{2}^\kappa, \quad j + k \geq 1, \]

(5.3)

where $R_{i}^\kappa$ are the Maurer–Cartan invariants, which multiply the invariantizations of the coefficients of the prolonged infinitesimal generator

\[ v_{\kappa} = \xi_{\kappa}(x, y, u) \frac{\partial}{\partial x} + \eta_{\kappa}(x, y, u) \frac{\partial}{\partial y} + \sum_{0 \leq j+k \leq n} \varphi_{\kappa}^{jk}(x, y, u^{(j+k)}) \frac{\partial}{\partial u_{jk}}, \]

(5.4)

which are given explicitly by the usual prolongation formula \[ [5.2] : \]

\[ \varphi_{\kappa}^{jk} = D_x D_y (\varphi_{\kappa} - \xi_{\kappa} u_x - \eta_{\kappa} u_y) + \xi_{\kappa} u_{j+1,k} + \eta_{\kappa} u_{k,j+1}. \]

(5.5)

### 6 Surfaces in conformal geometry

In this section, we focus our attention on the standard action of the conformal group $SO(4,1)$ on surfaces in $\mathbb{R}^3$, \[ [2]. \] Note that $\dim SO(4,1) = 10$. A basis for its infinitesimal generators is

\[
\begin{align*}
\frac{\partial}{\partial x}, & \quad \frac{\partial}{\partial y}, & \quad \frac{\partial}{\partial u}, & \quad x \frac{\partial}{\partial y} - y \frac{\partial}{\partial x}, & \quad x \frac{\partial}{\partial u} - u \frac{\partial}{\partial x}, & \quad y \frac{\partial}{\partial u} - u \frac{\partial}{\partial y}, \\
2x \frac{\partial}{\partial u} + y \frac{\partial}{\partial u} + u \frac{\partial}{\partial u}, & \quad (x^2 - y^2 - u^2) \frac{\partial}{\partial x} + 2xy \frac{\partial}{\partial y} + 2xu \frac{\partial}{\partial u}, \\
2xy \frac{\partial}{\partial x} + (y^2 - x^2 - u^2) \frac{\partial}{\partial y} + 2yu \frac{\partial}{\partial u}, & \quad 2xu \frac{\partial}{\partial u} + 2yu \frac{\partial}{\partial y} + (u^2 - x^2 - y^2) \frac{\partial}{\partial u}.
\end{align*}
\]

The maximal prolonged orbit dimensions \[ [3.4] \] are $r_0 = 3, r_1 = 5, r_2 = 8$ and $r_3 = 10$. The stabilization order is thus $s = 3$. The action is transitive on an open subset of $J^2$ and there are two independent differential invariants of order 3. Thus, by Theorem 5, the differential invariants of order 3 and 4 form a generating set. In this section we shall show that, under a certain non-degeneracy condition, all the differential invariants can be written in terms of the derivatives of a single third order differential invariant.

The argument goes in two steps. We first show that all the differential invariants of fourth order can be written in terms of the two third order differential invariants and their monotone derivatives, i.e. those obtained by applying the operators $D_1^2 D_2^2$. Then, the commutator trick of Theorem 8 allows us to reduce to a single generator.

We give two computational proofs of the first step. First using the properties of normalized invariants, Theorems 3 and 6, and a cross-section that corresponds to a hyperbolic quadratic form, second by using the properties of the Maurer–Cartan invariants, Theorems 7 and 4, along with a cross-section that corresponds to a degenerate quadratic form. We have used the symbolic computation software AIDA \[ [15] \] to compute the Maurer–Cartan matrix, the commutation rules and the syzygies, and the software diffalg \[ [4, 13] \] to operate the differential elimination.
6.1 Hyperbolic cross-section

The cross-section implicitly used in [38] is:

\[
x = y = u = u_x = u_y = u_{xx} = u_{yy} = u_{xxy} = u_{xyy} = 0, \quad u_{xy} = 1.
\]  

(6.1)

Thus, there are two basic third order differential invariants:

\[ I_{30} = \iota(u_{xxx}), \quad I_{03} = \iota(u_{yyy}), \]

and 5 of order 4, given by invariantization of the fourth order jet coordinates: \( I_{jk} = \iota(u_{jk}), j+k = 4 \). Since [6.1] defines a minimal order cross-section, Theorem [6] implies that \( \{I_{30}, I_{03}, I_{31}, I_{22}, I_{13}\} \) is a generating set of differential invariants.

To prove Theorem [1], we first show that \( I_{31}, I_{13} \) and \( I_{22} \) can be written in terms of \( \{I_{30}, I_{03}\} \) and their monotone derivatives. Using formula (3.8), the Maurer–Cartan matrix is found to have the form

\[
R = -\begin{pmatrix}
1 & 0 & 0 & \phi & 0 & 1 & 0 & \kappa & \sigma & \phi \\
0 & 1 & 0 & \psi & 1 & 0 & 0 & \sigma & \tau & -\psi
\end{pmatrix}
\]

where

\[
\phi = -\frac{1}{4} I_{30}, \quad \psi = \frac{1}{4} I_{03}, \quad \tau = 1 - \frac{1}{2} I_{13} - \frac{1}{8} I_{03}^2, \\
\sigma = \frac{1}{8} I_{30} I_{03} - \frac{1}{2} I_{22}, \quad \kappa = 1 - \frac{1}{2} I_{31} - \frac{1}{8} I_{30}^2.
\]

The first two are, in fact, the commutator invariants since, by (3.16), the invariant derivations \( \mathcal{D}_1 \) and \( \mathcal{D}_2 \) satisfy the commutation rule:

\[ [\mathcal{D}_2, \mathcal{D}_1] = \phi \mathcal{D}_1 + \psi \mathcal{D}_2. \]  

(6.2)

Implementing (3.5), (3.6), we deduce the following relationships among \( \{I_{30}, I_{03}, I_{40}, I_{31}, I_{22}, I_{13}, I_{04}\} \):

\[
E_{301}: \quad \mathcal{D}_1(I_{30}) - 3 I_{22} + \frac{3}{4} I_{30} I_{03} - I_{40}, \\
E_{302}: \quad \mathcal{D}_2(I_{30}) - 3 I_{13} - \frac{3}{4} I_{03}^2 + 6 - I_{31}, \\
E_{031}: \quad \mathcal{D}_1(I_{03}) - 3 I_{31} - \frac{3}{4} I_{30}^2 + 6 - I_{13}, \\
E_{032}: \quad \mathcal{D}_2(I_{03}) - 3 I_{22} + \frac{3}{4} I_{30} I_{03} - I_{04}, \\
S_{14}: \quad \mathcal{D}_2(I_{13}) - \mathcal{D}_1(I_{04}) + \frac{3}{2} I_{30} I_{22} - \frac{1}{4} I_{03} I_{04} + I_{30} I_{13}, \\
S_{23}: \quad \mathcal{D}_2(I_{22}) - \mathcal{D}_1(I_{13}) - \frac{3}{2} I_{03} (I_{31} + I_{13}) - \frac{1}{4} I_{30} (I_{22} + I_{04}) - \frac{1}{8} I_{03} (I_{30}^2 + I_{03}^2 - 20), \\
S_{32}: \quad \mathcal{D}_2(I_{31}) - \mathcal{D}_1(I_{22}) + \frac{3}{4} I_{03} (I_{40} + I_{22}) + \frac{3}{2} I_{30} (I_{13} + I_{31}) + \frac{1}{8} I_{30} (I_{03}^2 + I_{30}^2 - 20), \\
S_{41}: \quad \mathcal{D}_2(I_{40}) - \mathcal{D}_1(I_{31}) - I_{03} I_{31} - \frac{3}{4} I_{30} I_{22} + \frac{1}{4} I_{30} I_{40}.
\]

Taking the combination \( E_{302} - 3 E_{031} \) and \( E_{031} - 3 E_{302} \) we obtain:

\[
I_{31} = \frac{3}{2} - \frac{1}{4} \mathcal{D}_2(I_{30}) + \frac{3}{8} \mathcal{D}_1(I_{03}) + \frac{3}{32} (I_{03})^2 - \frac{9}{32} (I_{30})^2, \\
I_{13} = \frac{3}{2} - \frac{1}{4} \mathcal{D}_1(I_{03}) + \frac{3}{8} \mathcal{D}_2(I_{30}) - \frac{9}{32} (I_{03})^2 + \frac{3}{32} (I_{30})^2.
\]

Taking the combination

\[
128 \mathcal{D}_2(S_{32}) - 48 \mathcal{D}_1(S_{41}) - 16 \mathcal{D}_1(S_{23}) - 36 I_{03} S_{41} - 12 I_{03} S_{23} - 108 I_{30} S_{32} + 4 I_{30} S_{14} \\
- 48 \mathcal{D}_1 \mathcal{D}_2(E_{301}) - 16 D_{2}^2(E_{302}) + 48 D_{2}^2(E_{031}) + 16 D_{1}^2(E_{031}) \\
+ 36 I_{03} \mathcal{D}_1(E_{031}) + 88 I_{30} \mathcal{D}_2(E_{031}) - 12 I_{30} \mathcal{D}_1(E_{301}) - 4 I_{03} \mathcal{D}_2(E_{301})
\]

\[
+ 36 I_{30} \mathcal{D}_2 (E_{302}) + (18 I_{30}^2 + 40 I_{30}^2 + 48 \mathcal{D}_2 (I_{30}) + 24 \mathcal{D}_1 (I_{30})) E_{031} \\
+ (18 I_{30} I_{03} - 12 \mathcal{D}_1 (I_{30}) + 32 \mathcal{D}_2 (I_{03})) E_{301} \\
+ (42 I_{30}^2 + 48 \mathcal{D}_2 (I_{30})) E_{302} + (2 I_{30} I_{03} + 4 \mathcal{D}_1 (I_{30})) E_{032}
\]
leads to:

\[
I_{22} = 1 - \frac{A_{22}}{64 B_{22}},
\]

where

\[
A_{22} = 64 \mathcal{D}_2^3 (I_{30}) - 48 \mathcal{D}_2^2 (I_{30}) - 48 \mathcal{D}_1 \mathcal{D}_2 (I_{30}) - 64 \mathcal{D}_1^3 (I_{03}) \\
+ (36 \mathcal{D}_1^2 (I_{03}) + 48 \mathcal{D}_2^2 (I_{03}) - 52 \mathcal{D}_1 \mathcal{D}_2 (I_{30})) I_{03} \\
- (36 \mathcal{D}_2^2 (I_{30}) + 24 \mathcal{D}_1^2 (I_{30}) - 28 \mathcal{D}_1 \mathcal{D}_2 (I_{03})) I_{30} \\
+ 36 \mathcal{D}_2 (I_{30})^2 - 24 \mathcal{D}_1 (I_{30})^2 + 24 \mathcal{D}_1 (I_{03})^2 - 24 \mathcal{D}_2 (I_{30})^2 - 12 \mathcal{D}_2 (I_{30}) \mathcal{D}_1 (I_{03}) \\
+ (30 \mathcal{D}_1 (I_{03}) - 8 \mathcal{D}_2 (I_{30})) I_{03}^2 + (52 \mathcal{D}_2 (I_{03}) - 42 \mathcal{D}_1 (I_{30})) I_{30} I_{03} \\
- (30 \mathcal{D}_2 (I_{30}) + 2 \mathcal{D}_1 (I_{03})) I_{30}^2 + 3 I_{03}^4 - 3 I_{30}^4 + 3 I_{03}^2 - 3 I_{30}^2.
\]

and

\[
B_{22} = \mathcal{D}_1 (I_{30}) - \mathcal{D}_2 (I_{03}).
\]

We conclude that the two third order invariants \(I_{30}\) and \(I_{03}\) form a generating system. Moreover, since the generating invariants are, up to constant multiple, commutator invariants, we can use the commutator trick of Theorem 8 to generate them both from any single differential invariant. Indeed, when \(\mathcal{D}_2 \phi \neq 0\) the commutation rule (6.2) implies that

\[
\psi = \frac{\mathcal{D}_2 \mathcal{D}_1 \phi - \mathcal{D}_1 \mathcal{D}_2 \phi - \phi \mathcal{D}_1 \phi}{\mathcal{D}_2 \phi}.
\]

Similarly, when \(\mathcal{D}_1 \psi \neq 0\) we have

\[
\phi = \frac{\mathcal{D}_2 \mathcal{D}_1 \psi - \mathcal{D}_1 \math{D}_2 \psi - \psi \mathcal{D}_2 \psi}{\mathcal{D}_1 \psi}.
\]

Therefore, under the assumption that

\[
(\mathcal{D}_1 \psi)^2 + (\mathcal{D}_2 \phi)^2 \neq 0,
\]
a single differential invariant, of order 3, generates all the differential invariants for surfaces in conformal geometry.

### 6.2 Degenerate cross-section

In our second approach, we choose the “degenerate” cross-section

\[
x = y = u = u_x = u_y = u_{xx} = u_{xy} = u_{yy} = u_{xxy} = u_{xyy} = 0.
\]

Implementing (6.8), the new Maurer–Cartan matrix is:

\[
R = -\begin{pmatrix}
1 & 0 & 0 & 0 & 1 & 0 & -\psi & \sigma & \kappa & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & \phi & \tau & -\sigma & -\frac{1}{2} \phi
\end{pmatrix}.
\]
where
\[ \phi = I_{03}, \quad \psi = I_{30}, \quad \tau = \frac{1}{2} I_{13}, \quad \kappa = -\frac{1}{2} I_{31}, \quad \sigma = \frac{1}{2} I_{22}. \]

Again, \( \phi, \psi \) are the commutator invariants since \([D_2, D_1] = \phi D_1 + \psi D_2\). Theorem 7 tells us that the Maurer–Cartan invariants \( \{\phi, \psi, \kappa, \tau, \sigma\} \) form a generating set. We will show that \( \{\kappa, \tau, \sigma\} \) can be written in terms of \( \{\phi, \psi\} \) and their derivatives. We write those as \( \phi_{ij} \) to mean \( D_i^1 D_j^2 (\phi) \) and similarly for \( \psi, \kappa, \tau, \sigma \).

The non-zero syzygies of Theorem 4 are:
\[ \Delta_7 : \quad \phi_{10} + \psi_{01} - 2 \tau + 2 \kappa = 0, \]
\[ \Delta_8 : \quad \sigma_{01} - \tau_{10} - \frac{1}{2} \phi - 2 \phi \sigma - 2 \psi \tau = 0, \]
\[ \Delta_9 : \quad \sigma_{10} + \kappa_{01} - 2 \phi \kappa + 2 \psi \sigma = 0, \]
\[ \Delta_{10} : \quad \frac{1}{2} \phi_{10} - \tau + \psi \phi = 0. \]

The syzygies \( \Delta_{10} \) and \( \Delta_7 + 2 \Delta_{10} \) allow us to rewrite \( \tau \) and \( \kappa \) in terms of \( \phi, \psi \), namely:
\[ \kappa = -\frac{1}{2} \psi_{01} + \psi \phi, \quad \tau = \frac{1}{2} \phi_{10} + \psi \phi, \]
while the following combination
\[ 2 D_2 (\Delta_9) - 2 D_1 (\Delta_8) + 4 \sigma \Delta_7 - 6 \psi \Delta_8 - 6 \phi \Delta_9 - 2 \Delta_{10} \]
allows to express \( \sigma \) in terms of \( \phi, \psi, \tau, \kappa \) and their derivatives:
\[ \sigma = \frac{\tau_{02} + \kappa_{01} + 5 \psi \tau_{10} - 5 \phi \kappa_{01} + 2 \psi_0 \tau - 2 \phi_{01} \kappa + 6 \phi^2 \kappa + (6 \psi^2 + 1) \tau + \frac{1}{2} \psi \phi}{4(\kappa - \tau)}. \]

Observe that this exhibits a singular behavior at *umbilic points* where \( \kappa = \tau \).

Finally, since the generating invariants \( \{\phi, \psi\} \) are, up to a constant multiple, commutator invariants, we can generate one from the other by the same formulas (6.5), under the assumption that (6.5) holds.

### 7 Projective surfaces

The infinitesimal generators of the projective action of PSL(4) on \( \mathbb{R}^3 \) are
\[
\begin{align*}
\frac{\partial}{\partial x}, & \quad \frac{\partial}{\partial y}, & \quad \frac{\partial}{\partial u}, & \quad x \frac{\partial}{\partial x}, & \quad y \frac{\partial}{\partial x}, & \quad u \frac{\partial}{\partial x}, \\
x \frac{\partial}{\partial y}, & \quad y \frac{\partial}{\partial y}, & \quad u \frac{\partial}{\partial y}, & \quad x \frac{\partial}{\partial u}, & \quad y \frac{\partial}{\partial u}, & \quad u \frac{\partial}{\partial u}, \\
x^2 \frac{\partial}{\partial x} + xy \frac{\partial}{\partial y} + xu \frac{\partial}{\partial u}, & \quad xy \frac{\partial}{\partial x} + y^2 \frac{\partial}{\partial y} + yu \frac{\partial}{\partial u}, & \quad xu \frac{\partial}{\partial x} + yu \frac{\partial}{\partial y} + u^2 \frac{\partial}{\partial u}.
\end{align*}
\]

The generic prolonged orbit dimensions are \( r_0 = 3, \ r_1 = 5, \ r_2 = 8, \ r_3 = 12 \) and \( r_4 = 15 = \dim \text{PSL}(4) \), and so the stabilization order is \( s = 4 \).

We adopt the same strategy as in previous section to show that all the differential invariants are generated by a single fourth order differential invariants. The computations and formulae are nonetheless more challenging.

The section implicitly used in [ES] is:
\[ x = y = u = u_x = u_y = u_{xx} = u_{xy} = u_{xxy} = u_{xxy} = u_{xxx} = u_{xyy} = u_{xxyy} = 0, \]
\[ u_{xy} = u_{xxx} = u_{yyy} = 1. \] (7.1)

Thus, there are two basic fourth order differential invariants:

\[ I_{40} = \iota(u_{xxx}), \quad I_{04} = \iota(u_{yyy}), \]

and 6 of order 5, given by invariantization of the fifth order jet coordinates. Theorem 6 implies that the invariants \( \{ I_{40}, I_{04}, I_{41}, I_{32}, I_{23}, I_{14} \} \) forms a generating set of differential invariants.

The Maurer–Cartan matrix \([3.8]\) is

\[
R = -\begin{pmatrix}
1 & 0 & 0 & -2\psi & 0 & \frac{1}{2} & -\psi & \tau & 0 & -3\psi & -\tau & \frac{1}{3} & -\kappa & \frac{1}{3} \sigma - \frac{2}{3} \psi \\
0 & 1 & 0 & \frac{1}{2} & \sigma & 0 & 2\phi & \eta & 1 & 0 & 3\phi & \frac{1}{4} - \eta & -\sigma & \frac{3}{8} \phi + \frac{3}{8} \kappa
\end{pmatrix},
\]

where

\[
\phi = -\frac{1}{8} I_{04}, \quad \psi = \frac{1}{2} I_{40}, \quad \eta = -\frac{1}{2} I_{14} - \frac{1}{4}, \quad \tau = -\frac{1}{8} I_{23} + \frac{1}{8} I_{04}, \quad \sigma = -\frac{1}{2} I_{32} + \frac{1}{4} I_{40}, \quad \kappa = -\frac{1}{8} I_{41} - \frac{1}{4}.
\]

By Theorem 7 \([\phi, \psi, \tau, \sigma, \kappa]\) form a generating set of differential invariants. The invariant derivations satisfy the commutation rule;

\[
[\mathcal{D}_2, \mathcal{D}_1] = \phi \mathcal{D}_1 + \psi \mathcal{D}_2
\]

and so \( \phi, \psi \) are the commutator invariants.

The nonzero syzygies of Theorem \([\phi, \psi, \tau, \sigma, \kappa]\) of the generating set \( \{ \phi, \psi, \sigma, \tau, \kappa \} \) are given by:

\[
\begin{align*}
\Delta_4 : & \quad \phi_{10} + 2\psi_{01} + 2\eta - \phi \psi - \frac{1}{2} = 0, \\
\Delta_6 : & \quad \sigma_{10} - \kappa_{01} - \frac{3}{8} \phi + 3\phi \kappa + 2\psi \sigma = 0, \\
\Delta_8 : & \quad 2\phi_{10} + \psi_{01} - 2\kappa + \phi \psi + \frac{1}{2} = 0, \\
\Delta_9 : & \quad \eta_{10} - \tau_{01} - \frac{3}{8} \psi + 2\phi \tau + 3\psi \eta = 0, \\
\Delta_{12} : & \quad \Delta_4 + \Delta_8, \quad \Delta_{13} : \quad -\Delta_9, \quad \Delta_{14} : \quad -\Delta_6, \\
\Delta_{15} : & \quad \frac{1}{2} \tau_{10} - \frac{1}{2} \sigma_{01} + \frac{3}{8} \phi_{10} + \frac{3}{8} \psi_{01} - \frac{1}{4} \kappa + \frac{1}{4} \eta + 2\phi \sigma + 2\psi \tau = 0.
\end{align*}
\]

From \( \Delta_4 \) and \( \Delta_8 \) we immediately obtain:

\[ \eta = \frac{1}{4} - \frac{1}{2} \phi_{10} - \psi_{01} + \frac{1}{2} \phi \psi, \quad \kappa = \frac{1}{4} + \phi_{10} + \frac{1}{2} \psi_{01} + \frac{1}{2} \phi \psi. \]

Let \( P_1, P_2, P_3 \) be the differential polynomials obtained from \( \Delta_6, \Delta_9, \Delta_{15} \) after substitution of \( \kappa \) and \( \tau \):

\[
\begin{align*}
P_1 &= -\frac{1}{2} \tau_{10} + \frac{1}{2} \sigma_{01} - 2\phi \sigma - 2\tau \psi, \\
P_2 &= \frac{1}{2} \phi_{20} + \psi_{11} - \frac{1}{2} \phi_{10} \psi - \frac{1}{2} \phi \psi_{10} + \tau_{01} - \frac{3}{8} \psi - 2\phi \tau + \frac{3}{2} \psi \phi_{10} + 3 \psi \psi_{01} - \frac{3}{8} \phi \psi^2, \\
P_3 &= -\sigma_{10} + \phi_{11} + \phi \phi_{10} + \frac{3}{2} \psi \psi_{01} + \frac{1}{2} \psi_{02} + \frac{1}{2} \phi \psi_{01} - \frac{3}{8} \phi - 3 \phi \phi_{10} - \frac{3}{8} \phi \psi_{01} \\
&\quad - \frac{3}{8} \phi^2 \psi - 2\psi \sigma.
\end{align*}
\]

To obtain \( \tau \) and \( \sigma \) we proceed with a differential elimination \([4, 12, 13, 14]\) on \( \{ P_1, P_2, P_3 \} \). We use a ranking where

\[
\psi < \phi < \phi_{01} < \phi_{10} < \psi_{01} < \phi_{10} < \psi_{02} < \psi_{11} < \phi_{11} < \phi_{20} < \cdots \]

\[
\cdots < \tau < \sigma < \tau_{01} < \sigma_{01} < \tau_{10} < \sigma_{10} < \tau_{02} < \sigma_{02} < \tau_{11} < \sigma_{11} < \tau_{20} < \sigma_{20} < \cdots.
\]

For this ranking, the leaders of \( P_1, P_2, P_3 \) are, respectively, \( \tau_{10}, \tau_{01}, \sigma_{10} \).
We first form the ∆-polynomial (cross-derivative) of $P_1$ and $P_2$ and reduce it with respect to $\{P_1, P_2, P_3\}$. We obtain a polynomial $P_4$ with leader $\sigma_{02}$. We then take the ∆-polynomial of $P_3$ and $P_4$ and reduce it with respect to $\{P_1, P_2, P_3, P_4\}$ to obtain a differential polynomial $P_5$ with leader $\sigma_{01}$. On one hand, if we reduce now $P_4$ by $\{P_1, P_2, P_3, P_5\}$ we obtain a differential polynomial $P$ with leader $\sigma$. On the other hand, if we form the ∆-polynomial of $P_3$ and $P_5$, reduce it by $\{P_1, P_2, P_3, P_5\}$ we obtain a differential polynomial $Q$ with leader $\sigma$. The polynomial $P$ and $Q$ are linear in $\sigma$ and $\tau$ so that we can solve for those two invariants in terms of $\phi$, $\psi$ and their derivatives. The explicit formulas are rather long (available from the authors on request), but not particularly enlightening. We conclude that the commutator invariants $\phi$, $\psi$ form a generating set. Finally, we can use either (6.3) or (6.4), to generate one commutator invariant from the other, and thereby establish Theorem 2.
