Abstract: Short-distance singularities in lattice correlators can modify their Symanzik expansion by leading to additional $O(a)$ lattice artifacts. At the example of the chiral condensate and the topological susceptibility, we show how to account for these lattice artifacts for Wilson twisted mass fermions and show that the property of automatic $O(a)$ improvement is preserved at maximal twist.
1 Introduction

In two recent papers [1, 2] we carried out a calculation for the chiral condensate and the topological susceptibility in the chiral and the continuum limit. In these works, we performed an $O(a^2)$ scaling towards the continuum limit. However, quantities such as the chiral condensate or the topological susceptibility are related to correlators where the coordinates of their fields content are integrated over the whole space-time volume [3]. This integration generates contact terms when two or more fields are located at the same point. The presence of contact terms can generate short-distance singularities and when this happens, the renormalization and the discretization effects of these correlators need a specific discussion. As we will show in this paper for the setup of maximally twisted mass fermions used in refs. [1, 2], even in the presence of these short distance singularities automatic $O(a)$-improvement is preserved at maximal twist, thus justifying the strategy to perform an $O(a^2)$ scaling, as done in refs. [1, 2].

Cut-off effects in lattice correlators are described by the so-called Symanzik effective theory [4, 5]. One of the basic assumptions for the validity of the Symanzik expansion is the absence of contact terms in the lattice correlators. These short-distance singularities alter the form of the lattice artifacts predicted by the Symanzik effective theory. This has been discussed already for Wilson fermions in ref. [3], where specific $O(a)$ counterterms had to be added to the lattice correlators to cancel $O(a)$ terms arising from the presence of short distance singularities in the lattice correlators.

Also the property of automatic $O(a)$ improvement [6] for Wilson twisted mass fermions [7] at maximal twist relies on the validity of the Symanzik expansion of lattice correlators. It is natural then to question if this property is still valid in the presence of contact terms. The tool to analyze the nature of the contact terms is the Operator Product Expansion (OPE) [8]. Using the OPE, it is possible to analyze if additional terms need to be added to the standard Symanzik expansion of lattice correlators. The symmetry transformation
properties of these terms will depend on the quantity to be considered and the corresponding nature of the contact terms and on the lattice symmetries.

While we concentrate here on the example of the chiral condensate and the topological susceptibility, we mention that a similar problem emerges for the vacuum polarization function needed to evaluate hadronic contributions to electroweak observables [9], in particular the muon anomalous magnetic moment [10]. In the work here, we show which of such terms relevant for the chiral condensate and the topological susceptibility appear in this case and we will demonstrate that the property of automatic O($a$) improvement is still preserved. A first account of these results has been given in refs. [11, 12].

2 Mixed action formulation and automatic O($a$) improvement

To analyze the cutoff effects of the chiral condensate and the topological susceptibility, we make use of a mixed action approach for the valence and sea quarks. In this section, we briefly recall how the property of automatic O($a$) improvement extends to this particular framework. For simplicity, we consider a Wilson twisted mass (Wtm) doublet of sea quarks and $2N_v$ Wilson twisted mass valence doublets. The extension to the case of $N_f = 2+1+1$ Wilson twisted mass quarks [13] is straightforward once the renormalized quark masses have been properly matched.

The lattice action

$$S = S_G + S_F + S_{F,\text{val}} + S_{\text{gh}},$$

(2.1)

has a term for the sea quarks that reads

$$S_F = a^4 \sum_x \overline{\chi}_s(x) \left[ D_m + i\mu_s \gamma_5 \tau^3 \right] \chi_s(x),$$

(2.2)

where

$$D_m = \frac{1}{2} \left[ \gamma \mu \left( \nabla_\mu + \nabla^*_\mu \right) - a \nabla_\mu \nabla^*_\mu \right] + m_0,$$

(2.3)

is the usual Wilson operator and $m_0$, $\mu_s$ are the bare untwisted and twisted quark mass. The theory contains also $2N_v$ valence quark doublets with the action

$$S_{F,\text{val}} = a^4 \sum_x \sum_{v=1}^{2N_v} \overline{\chi}_v(x) \left[ D_m + i\mu_v \gamma_5 \tau^3 \right] \chi_v(x),$$

(2.4)

where $\mu_v$ denotes the valence bare twisted mass. The fermion doublets are $\chi^T_v = (u_v, d_v)$ and $\chi^T_s = (u_s, d_s)$.

The action $S_{\text{gh}}$ for the ghost field $\phi_v$, that is a complex commuting spinor field, is needed to cancel the valence fermionic determinant. Each valence quark field has a corresponding ghost with the same lattice action and the same value for the bare mass $\mu_v$. For the discussion that follows, we do not need the exact form of the ghost lattice action, as for the gauge lattice action $S_G$. An important remark is that the ghost lattice action is defined in order to guarantee the convergence of the Gaussian integral over the field $\phi_v$ [14].
The long distance properties of the lattice theory close to the continuum limit are described in terms of the Symanzik effective theory with the action

\[ S_{\text{eff}} = S_0 + aS_1 + \ldots , \quad (2.5) \]

where the leading term, \( S_0 \), is the action of the target continuum theory with properly renormalized parameters. The higher order terms are linear combinations of higher-dimensional operators

\[ S_1 = \int d^4x \sum_i c_i (g_0^2) O_i(x) , \quad (2.6) \]

where \( O_i(x) \) respect the symmetries of the lattice action and we omit for simplicity the dependence on the renormalization scale.

A correlation function of products of multiplicatively renormalizable lattice fields, here denoted by \( \phi_R = Z_{\phi} \phi \), at separated points \( x_i \)

\[ G(x_1, \ldots , x_n) = \langle \phi_R(x_1) \cdots \phi_R(x_n) \rangle \equiv \langle \Phi_R \rangle \quad (2.7) \]

takes the form

\[ \langle \Phi_R \rangle = \langle \Phi_0 \rangle_0 - a \langle \Phi_0 S_1 \rangle_0 + a \langle \Phi_1 \rangle_0 + O(a^2) , \quad (2.8) \]

where

\[ \langle \Phi_0 \rangle_0 \equiv \langle \phi_0(x_1) \cdots \phi_0(x_n) \rangle_0 , \quad (2.9) \]

\[ \langle \Phi_1 \rangle_0 \equiv \sum_{k=1}^n \langle \phi_0(x_1) \cdots \phi_1(x_k) \cdots \phi_0(x_n) \rangle_0 , \quad (2.10) \]

and \( \phi_0, \phi_1 \) are renormalized continuum fields. \( \phi_1 \) is a linear combination of local operators of dimension \( d_\phi + 1 \) that depend on the specific operator \( \phi \) and are classified according to the lattice symmetries transformation properties of \( \phi \). The expectation values on the right hand side of eq. (2.8) are to be taken in the continuum theory with the action \( S_0 \).

For the sea and valence quarks, the higher-dimensional operators contributing to \( S_1 \) of the Symanzik effective action are the same. Using the equations of motion for the quark fields, a possible list of \( O(a) \) terms is \[5, 15\]

\[ O_1^{(s,v)} = i\chi_{s,v}(x)\sigma_{\mu\nu}F_{\mu\nu}\chi_{s,v}(x) , \quad O_2^{(s,v)} = \mu_{s,v}^2 \chi_{s,v}(x)\chi_{s,v}(x) . \quad (2.11) \]

We omit from the list all the operators proportional to the untwisted quark mass. These terms do not contribute to the effective theory up to and including the \( O(a) \) terms, if we tune our lattice action to be at maximal twist, i.e. if we set the renormalized untwisted quark mass to vanish in the continuum limit.

### 2.1 Automatic \( O(a) \) improvement

Automatic \( O(a) \) improvement \[6\] is the property of Wtm that physical correlation functions made of multiplicatively renormalizable fields are free from \( O(a) \) effects. This applies when the lattice parameters are tuned to obtain the vanishing of the renormalized untwisted quark mass, \( m_R = 0 \), in the continuum limit.
From the lattice perspective, this corresponds to setting the bare untwisted mass $m_0$ to its critical value $m_{cr}$. The exact way this is achieved is not relevant for what follows, but for a discussion and further references on this topic see ref. [16].

The relevant symmetries to prove automatic $O(a)$ improvement are the discrete chiral symmetry

$$R^{1,2}_5: \begin{cases} 
\chi_i(x) \rightarrow i\gamma_5\tau^{1,2}\chi_i(x) & i = \text{sea, valence} \\
\overline{\chi}_i(x) \rightarrow \overline{\chi}_i(x)i\gamma_5\tau^{1,2} & i = \text{sea, valence}
\end{cases}$$

and a symmetry that essentially counts the dimensions of the operators

$$D: \begin{cases} 
U(x;\mu) \rightarrow U^\dagger(-x - a\hat{\mu};\mu), \\
\chi_i(x) \rightarrow e^{3i\pi/2}\chi_i(-x) & i = \text{sea, valence} \\
\overline{\chi}_i(x) \rightarrow \overline{\chi}_i(-x)e^{3i\pi/2} & i = \text{sea, valence}.
\end{cases}$$

The equivalent transformations for continuum fields, that with abuse of notation we indicate in the same way, are the same for the fermion fields, whereas for the gauge fields the $D$ transformation is $A_\mu(x) \rightarrow -A_\mu(-x)$. To include the twisted mass in the counting of the dimensions of the operators appearing in the lattice and continuum Lagrangian, one introduces the spurionic symmetry

$$\tilde{D} = D \times [\mu_i \rightarrow -\mu_i] \quad i = \text{sea, valence}.$$  \hfill (2.14)

The lattice action is invariant under the $R^{1,2}_5 \times \tilde{D}$ transformation. If the target continuum theory has a vanishing renormalized untwisted mass, $m_R = 0$, it is invariant separately under the $R^{1,2}_5$ and the $\tilde{D}$ transformations. This immediately implies that all the higher-dimensional operators in the Symanzik expansion contributing to $S_1$ are odd under $R^{1,2}_5$, thus they vanish once inserted in $R^{1,2}_5$-even correlation functions. The same argument applies for the higher-dimensional operators appearing in the effective theory representations of local operators, such as axial currents or pseudoscalar densities. We remind that the $R^{1,2}_5$-even correlation functions in the continuum are what we denote as physical correlation functions, because in the twisted basis where we are working, the $R^{1,2}_5$ symmetry transformation is a physical flavor transformation.

### 3 Chiral condensate

The Banks-Casher relation [17] connects the low lying spectrum of the Dirac operator with the spontaneous chiral symmetry breaking in the following way

$$\lim_{\lambda \rightarrow 0} \lim_{\mu_s \rightarrow 0} \lim_{V \rightarrow \infty} \rho(\lambda, \mu_s) = \frac{\Sigma}{\pi}.$$  \hfill (3.1)

Eq. (3.1) relates the chiral condensate $\Sigma$ to the spectral density $\rho(\lambda, \mu_s)$. The method based on spectral projectors introduced in [3] offers a new strategy to compute spectral observables, such as the chiral condensate, in an affordable way [1, 2, 18]. Moreover it allows us, via the connection to density chains, to compute this quantity using a representation
which is free of short distance singularities and therefore leads to the correct continuum limit.

The integrated spectral density, i.e. the mode number \( \nu(M, \mu_s) \), is defined as the number of eigenvalues \( \lambda \) of the hermitian Dirac operator \( D^\dagger D \) below a certain threshold value \( M^2 \). To study the renormalization and \( O(a) \) cutoff effects properties of the mode number, it is advantageous to consider the spectral sums \( \sigma_k(\mu_v, \mu_s) \), which are directly related to the mode number through the following expression

\[
\sigma_k(\mu_v, \mu_s) = \frac{1}{V} \int_0^\infty dM \nu(M, \mu_s) \frac{2kM}{(M^2 + \mu_v^2)^{k+1}},
\]

(3.2)

where \( V \) is the space-time volume. To relate the mode number to a multi-local correlation function, it is convenient to write the spectral sums \( \sigma_k \) in terms of density chain correlation functions of twisted valence quarks with mass \( \mu_v \). In terms of twisted mass density chains, the spectral sum \( \sigma_3 \) reads

\[
\sigma_3(\mu_v, \mu_s) = -a^{20} \sum_{x_1, \ldots, x_5} \langle P^+_{12}(x_1) P^+_{23}(x_2) P^+_{34}(x_3) P^+_{45}(x_4) P^+_{56}(x_5) P^-_{61}(0) \rangle,
\]

(3.3)

where

\[
P^+_{ab} = \mathbf{\bar{\chi}}_a \gamma_5 \tau^+ \chi_b = \mathbf{\bar{u}}_a \gamma_5 d_b,
\]

(3.4)

\[
P^-_{ab} = \mathbf{\bar{\chi}}_a \gamma_5 \tau^- \chi_b = \mathbf{\bar{d}}_a \gamma_5 u_b,
\]

(3.5)

are charged pseudoscalar densities, \( \tau^\pm \) are defined in flavor space, \( \mu_v \) is the valence twisted mass and \( \mu_s \) is the sea twisted mass that plays the role of the physical quark mass. In this particular example, we add 6 doublets to the theory, which is the minimum number of flavors that still guarantees the renormalizability, as it was stated in ref. [3].

The spectral density and therefore the mode number is directly linked to the chiral condensate [3]. The representation of the mode number and the spectral density of the Wilson operator through density chain correlators as in eq. (3.3) allows to discuss the renormalization and improvement properties of such quantities. This is particularly important when computing the mode number using Wilson twisted mass fermions at maximal twist. The maximal twist condition, \( m_R = 0 \), should guarantee automatic \( O(a) \) improvement of all physical quantities [6]. The conditional is appropriate, because density chain correlators are affected by short distance singularities and the integration over the whole space-time of such singularities generates additional \( O(a) \) terms that could spoil the property of automatic \( O(a) \) improvement. The short-distance singularities of a product of two operators can be studied with the operator product expansion (OPE).

For generic values of the untwisted and twisted mass, the Symanzik expansion for the renormalized observable introduced in eq. (3.3) reads

\[
\sigma_{3,R}(\mu_v, \mu_s) = \sigma_{3,R}(\mu_v, \mu_s)_0 + a \sigma_{3,R}(\mu_v, \mu_s)_1 + a^2 \sigma_{3,R}(\mu_v, \mu_s)_{ct},
\]

(3.6)

where

\[
\sigma_{3,R}(\mu_v, \mu_s)_0 = - \int d^4x_1 d^4x_2 d^4x_3 d^4x_4 d^4x_5 \langle P^+_{12}(x_1) P^+_{23}(x_2) P^+_{34}(x_3) P^+_{45}(x_4) P^+_{56}(x_5) P^-_{61}(0) \rangle_0,
\]

(3.7)
is the continuum expectation value. The standard terms of the Symanzik expansion are

\[ \sigma_{3,R}(\mu_v, \mu_s)_1 = \int d^4x_1 d^4x_2 d^4x_3 d^4x_4 \langle x_1 | P^{+}_{12}(x_1) P^{+}_{23}(x_2) P_{34}(x_3) P^{+}_{45}(x_4) P_{56}(x_5) P_{61}(0) S_1 \rangle_0 \]

\(- 6c_P(g_0^2) m_v \int d^4x_1 d^4x_2 d^4x_3 d^4x_4 d^4x_5 \langle x_1 | P^{+}_{12}(x_1) P^{+}_{23}(x_2) P^{+}_{34}(x_3) P_{45}(x_4) P^{+}_{56}(x_5) P_{61}(0) \rangle_0 \) \quad (3.8)

where the leading O(a) corrections to the pseudoscalar densities are

\[ (\delta P)^{\pm}_{ij}(x) = m_v c_P(g_0^2) P^{\pm}_{ij}(x). \] \quad (3.9)

We recall that all the valence quarks have the same mass values.

The O(a) terms arising from the short-distance singularities, denoted by \( \sigma_{3,R}(\mu_v, \mu_s)_{ct} \), get contributions from the OPE of two or more pseudoscalar densities at a coincident space-time point. The lowest dimensional operator that appears in the short-distance expansion (SDE) of two pseudoscalar densities on the lattice is

\[ \bar{\pi}_a(x) \gamma_5 d_a(x) \bar{d}_b(0) \gamma_5 u_c(0) \sim C_{PP}(x) \frac{1}{a^2} \bar{\pi}_a(0) u_c(0), \] \quad (3.10)

where \( C_{PP}(x) \) is a dimensionless coefficient function. Once we sum over \( x \) the product of the two pseudoscalar densities, this short distance singularity will contribute a term

\[ \sum_x \langle \bar{\pi}_a(x) \gamma_5 d_b(x) \bar{d}_b(0) \gamma_5 u_c(0) \rangle \rightarrow a \langle \bar{\pi}_a(0) u_c(0) \rangle, \] \quad (3.11)

to the Symanzik expansion. If we now consider the lowest dimensional operator contributing to the SDE of 3 pseudoscalar densities at the same point, we get

\[ \bar{\pi}_a(x_2) \gamma_5 d_b(x_2) \bar{d}_b(x_1) \gamma_5 u_c(x_1) \bar{\pi}_a(0) \gamma_5 d_d(0) \sim_{x_1, x_2 \rightarrow 0} C(x_2, x_1) \frac{1}{a^3} \bar{\pi}_a(0) \gamma_5 d_d(0), \] \quad (3.12)

where \( C(x_2, x_1) \) is a dimensionless function. If we now sum over \( x_2 \) and \( x_1 \), the contribution of the short-distance singularities to the Symanzik expansion is an O(a²) effect. Products of even more pseudoscalar densities in the same point will give contributions of higher power of the lattice spacing. So up to corrections of O(a²), the contact terms contributions to the Symanzik expansion are

\begin{align*}
\sigma_{3,R}(\mu_v, \mu_s)_{ct} &= \int d^4x_2 d^4x_3 d^4x_4 d^4x_5 \langle x_2 | S^{+}_{13}(x_2) P^{+}_{34}(x_3) P^{+}_{45}(x_4) P_{56}(x_5) P_{61}(0) \rangle_0 \\
&+ \int d^4x_2 d^4x_3 d^4x_4 d^4x_5 \langle x_2 | S^{+}_{12}(x_2) P^{+}_{23}(x_2) P^{+}_{34}(x_3) P_{45}(x_4) P_{56}(x_5) S^{+}_{61}(0) \rangle_0 \\
&+ \int d^4x_2 d^4x_3 d^4x_4 d^4x_5 \langle x_2 | S^{+}_{12}(x_2) S^{+}_{23}(x_2) P^{+}_{34}(x_3) P_{45}(x_4) P_{56}(x_5) S^{+}_{61}(0) \rangle_0 \\
&+ \int d^4x_2 d^4x_3 d^4x_4 d^4x_5 \langle x_2 | P^{+}_{12}(x_2) P^{+}_{23}(x_2) P^{+}_{34}(x_3) P_{45}(x_4) S^{+}_{61}(0) \rangle_0 \\
&+ \int d^4x_2 d^4x_3 d^4x_4 d^4x_5 \langle x_2 | P^{+}_{12}(x_2) P^{+}_{23}(x_2) S^{+}_{34}(x_3) P_{45}(x_4) P_{56}(x_5) S^{+}_{61}(0) \rangle_0 \\
&+ \int d^4x_2 d^4x_3 d^4x_4 d^4x_5 \langle x_2 | P^{+}_{12}(x_2) S^{+}_{23}(x_2) P^{+}_{34}(x_3) S^{+}_{45}(x_4) P_{56}(x_5) S^{+}_{61}(0) \rangle_0 \\
&+ \int d^4x_2 d^4x_3 d^4x_4 d^4x_5 \langle x_2 | S^{+}_{12}(x_2) P^{+}_{23}(x_2) P^{+}_{34}(x_3) S^{+}_{45}(x_4) P_{56}(x_5) S^{+}_{61}(0) \rangle_0 \quad (3.13)
\end{align*}
where \( S_{ac}^{\pm} = \overline{x}_a \frac{1}{2} (1 \pm \tau^3) \chi_c \), i.e. \( S_{ac}^{\pm} = \overline{u}_a e_c \), \( S_{al}^{\pm} = \overline{d}_a d_c \).

For the discussion of the contact terms, we keep generic values for the twisted and untwisted quark masses. To show that the contact terms \( \sigma_{3,R}(\mu_c, \mu_\ell) \) vanish at maximal twist, we group them and as an example we consider the two terms

\[
\int d^4 x d^4 x_d d^4 d^4 x_5 \left\{ S_{13}^{\pm}(x_3) P_{34}^{\pm}(x_3) P_{45}^{\pm}(x_4) P_{56}^{\pm}(x_5) S_{61}^{\pm}(0) \right\}_0 + \\
+ \int d^4 x d^4 x_d d^4 d^4 x_5 \left\{ P_{23}^{\pm}(x_2) P_{34}^{\pm}(x_3) P_{45}^{\pm}(x_4) P_{56}^{\pm}(x_5) S_{62}^{\pm}(0) \right\}_0 .
\]

(3.14)

We can now use the integrated non-singlet axial Ward identity (WI) to rewrite eq. (3.14) in a convenient form. For twisted mass fermions at a generic twist angle, the WI reads

\[
\int d^4 x d^4 x_d d^4 d^4 x_5 \left\{ S_{13}^{\pm}(x_3) P_{34}^{\pm}(x_3) P_{45}^{\pm}(x_4) P_{56}^{\pm}(x_5) S_{61}^{\pm}(0) \right\}_0 + \\
+ \int d^4 x d^4 x_d d^4 d^4 x_5 \left\{ P_{23}^{\pm}(x_2) P_{34}^{\pm}(x_3) P_{45}^{\pm}(x_4) P_{56}^{\pm}(x_5) S_{62}^{\pm}(0) \right\}_0 = 2m_\nu \int d^4 x d^4 x_d d^4 d^4 x_5 \int d^4 x_1 \left\{ P_{12}^{\pm}(x_1) P_{13}^{\pm}(x_2) P_{23}^{\pm}(x_3) P_{34}^{\pm}(x_4) P_{45}^{\pm}(x_5) P_{56}^{\pm}(0) \right\}_0 .
\]

(3.15)

All the other terms stemming from the short distance singularities can be treated in an analogous manner. Thus, tuning the lattice parameters to achieve a maximal twist condition for the sea and valence quarks guarantees that all the O(\( a \)) terms including the non-standard ones coming from the short-distance singularities of the correlator vanish.

For the sake of simplicity we have chosen to write a particular example for six flavors, however, a generalization of this derivation for a generic number of flavors is straightforward.

In principle, one should also be worried about short-distance singularities in the continuum Symanzik effective theory. If we assume that the effective theory is regularized with a Ginsparg-Wilson regulator, then chiral symmetry implies that the leading term in the OPE of two pseudoscalar densities are all of dimension 4 with Wilson coefficients behaving as \( 1/|x|^2 \) up to logarithmic corrections. This singularities are integrable and thus do not harm our argument of automatic O(\( a \)) improvement.

## 4 Topological susceptibility

In the continuum, the relation between the topological charge \( Q \) and the density chain correlation functions can be established via the equation \( \text{Tr}\{ \gamma_5 f(D) \} = f(0) Q \), where \( D \) is the Dirac operator and \( f(\lambda) \) is any continuous function that decays rapidly enough at infinity [19].

With twisted mass fermions, a sample expression for the topological susceptibility in a space-time volume \( V \) is:

\[
\chi_{\text{top}} = \mu_6^6 C_{1;2} \equiv \frac{\langle Q^2 \rangle}{V} ,
\]

(4.1)

where

\[
C_{1;2} = a^{20} \sum_{x_1 \ldots x_5} \langle S_{11}^{\pm}(x_1) P_{12}^{\pm}(x_2) P_{23}^{\pm}(x_3) P_{34}^{\pm}(x_4) S_{45}^{\pm}(x_5) P_{56}^{\pm}(0) \rangle ,
\]

(4.2)
\[ S_{ij}^\pm = \bar{\chi}_i \tau^\pm \chi_j, \quad P_{ij}^\pm = \bar{\chi}_i \tau^\pm \gamma_5 \chi_j. \]

This definition of \( \chi_{\text{top}} \) is interesting, because it is expressed in terms of a correlation function of local operators, thus it can be used to discuss renormalization and \( O(a) \) improvement\(^1\). Additionally, it is directly related to the following spectral sum:

\[ \sigma_{k,l}(\mu) = \left\langle \text{Tr} \left\{ \gamma_5 (D\dagger D + \mu^2)^{-k} \right\} \text{Tr} \left\{ \gamma_5 (D\dagger D + \mu^2)^{-l} \right\} \right\rangle. \]

and hence its computation can be carried out with the spectral projector method \(^{20}\).

The expression for the renormalized susceptibility, \( \chi_{\text{top},R} \), is

\[ \chi_{\text{top},R} = \frac{Z_S^2}{Z_P^2} \frac{\langle Q^2 \rangle}{V}, \]

where \( Z_S \) and \( Z_P \) are the renormalization constants of the scalar and pseudoscalar densities, respectively. In the following, we will drop the subscript \( R \) and always consider the renormalized topological susceptibility.

In eq. (4.1), we take \( Q^2 \) expressed in terms of two closed density chains – one with 4 densities and the other with only 2, such that the total number is not smaller than 5, to guarantee the absence of non-integrable short-distance singularities. The \( \chi_{\text{top}} \) given by the above formula is \( \mathcal{R}_S^{1,2} \)-even up to a charge conjugation transformation:

\[ C: \begin{cases} \chi_i(x) \to C^{-1} \chi_i(x)^T, \\ \bar{\chi}_i(x) \to -\chi_i(x)^T C, \end{cases} \]

where \( C = i\gamma_0 \gamma_2 \) can be chosen. Thus, the standard terms in the Symanzik expansion of \( C_{1,2} \) vanish. However, automatic \( O(a) \) improvement can still be spoiled by contact terms.

The Symanzik expansion of \( C_{1,2} \)

\[ C_{1,2} = (C_{1,2})_0 + a (C_{1,2})_1 + a (\delta C_{1,2})_{\text{ct}} \]

contains the continuum correlator \( (C_{1,2})_0 \) and the standard \( O(a) \) terms \( (C_{1,2})_1 \) coming from the higher dimensional operator in the effective action and the effective operators. Additional terms labeled here as \( (\delta C_{1,2})_{\text{ct}} \) correspond to the \( O(a) \) terms arising from the short distance singularities in the product of two densities. The product of 2 pseudoscalar densities is already discussed in the previous section. The lowest dimensional operator appearing in the OPE of the product of a scalar and pseudoscalar density on the lattice is

\[ \bar{u}_a(x)db(x)\bar{d}_b(0)\gamma_5 u_c(0) \sim C_{\text{SP}}(x) \frac{1}{a^3} u_a(0)\gamma_5 u_c(0), \]

where \( C_{\text{SP}}(x) \) is a dimensionless coefficient function. Once we sum over \( x \) the product of the two pseudoscalar densities, this short distance singularity will contribute a term

\[ \sum_x \langle \bar{u}_a(x)db(x)\bar{d}_b(0)\gamma_5 u_c(0) \rangle \to a \langle u_a(0)\gamma_5 u_c(0) \rangle, \]

\(^1\)Note that the example that we discuss differs from the one in ref. [19], since we are interested in a formula that can be evaluated with the spectral projector method and thus one that can be expressed using the Hermitian Dirac operator \( D\dagger D \).
to the Symanzik expansion. As for the case of the scalar condensate, contact terms arising when 3 or more densities are at the same point lead to cut-off effects of $O(a^n)$ with $n \geq 2$. The $O(a)$ corrections arising from the short-distance singularities are

$$\langle \delta C_{1:2} \rangle_{ct} = c(g_0^2) \int d^4x d^4y d^4z d^4t \delta \langle P_{42}^+ (x_2) P_{23}^+ (x_3) P_{34}^+ (x_4) S_{56}^+ (x_5) P_{65}^- (0) \rangle_0$$

$$+ c(g_0^2) \int d^4x d^4y d^4z d^4t \langle P_{31}^+ (x_1) P_{12}^+ (x_2) P_{24}^+ (x_3) S_{56}^+ (x_5) P_{65}^- (0) \rangle_0$$

$$+ c(g_0^2) \int d^4x d^4y d^4z d^4t \langle S_{41}^+ (x_1) S_{13}^+ (x_3) P_{34}^+ (x_4) S_{56}^+ (x_5) P_{65}^- (0) \rangle_0$$

$$+ c(g_0^2) \int d^4x d^4y d^4z d^4t \langle S_{41}^+ (x_1) P_{12}^+ (x_2) S_{24}^+ (x_4) S_{56}^+ (x_5) P_{65}^- (0) \rangle_0$$

$$+ c(g_0^2) \int d^4x d^4y d^4z d^4t \langle S_{41}^+ (x_1) P_{12}^+ (x_2) P_{23}^+ (x_3) P_{34}^+ (x_4) P_{56}^+ (0) \rangle_0$$

$$+ c(g_0^2) \int d^4x d^4y d^4z d^4t \langle S_{41}^+ (x_1) P_{12}^+ (x_2) P_{23}^+ (x_3) P_{34}^+ (x_4) P_{56}^+ (0) \rangle_0,$$

(4.9)

where $P_{ij}^{\pm} = \chi_i \left( \frac{\gamma_\pm + \gamma_5}{2} \right) \gamma_5 \chi_j$. We study now how $\langle \delta C_{1:2} \rangle_{ct}$ transforms under the $R_5^{1,2}$ symmetry. Let us start considering the first two terms in eq. (4.9). If we perform an $R_5^1$ transformation only for doublets labeled by 1, 2, 3, 4, we obtain

$$\langle P_{42}^+ P_{23}^+ P_{34}^+ S_{56}^+ P_{65}^- \rangle_0 + \langle P_{31}^+ P_{12}^+ P_{23}^+ S_{56}^+ P_{65}^- \rangle_0$$

$$\Rightarrow R_5^1 \rightarrow - \langle S_{41}^+ S_{13}^+ P_{34}^+ S_{56}^+ P_{65}^- \rangle_0 - \langle S_{41}^+ P_{12}^+ S_{24}^+ S_{56}^+ P_{65}^- \rangle_0$$

(4.10)

Up to a relabeling of flavors ($4 \rightarrow 3$, $3 \rightarrow 2$, $2 \rightarrow 1$ in the first term and $1 \rightarrow 2$, $2 \rightarrow 3$, $3 \rightarrow 4$ in the second one), this linear combination is odd under $R_5^{1,2}$, i.e. it vanishes for twisted mass fermions at maximal twist. The same procedure can be used for the last 2 terms of eq. (4.9) applying the $R_5^1$ transformation only for doublets labeled by 5, 6. For the third and fourth term in eq. (4.9), after the $R_5^1$ transformation on the doublets 1 to 4, we obtain

$$\langle S_{41}^+ S_{13}^+ P_{34}^+ S_{56}^+ P_{65}^- \rangle_0 + \langle S_{41}^+ P_{12}^+ S_{24}^+ S_{56}^+ P_{65}^- \rangle_0$$

$$\Rightarrow R_5^1 \rightarrow - \langle S_{41}^+ S_{13}^+ P_{34}^+ S_{56}^+ P_{65}^- \rangle_0 - \langle S_{41}^+ P_{12}^+ S_{24}^+ S_{56}^+ P_{65}^- \rangle_0$$

(4.11)

where the relabeling of the doublets is $1 \leftrightarrow 4$, $2 \leftrightarrow 3$. Thus, also the sum of the third and fourth terms in eq. (4.9) is odd under the symmetries of the action and thus vanishes. Moreover, this proof holds also in the general case – for any density chain that can be written in terms of $D^1 D$ (i.e. containing an even number of pseudoscalar and scalar densities).
5 Concluding remarks

When using density chain correlators to compute the chiral condensate and the topological susceptibility as suggested in ref. [3], short distance singularities appear. Thus, the influence of resulting contact terms needs to be analyzed. In particular, it is a priori unclear, whether the property of automatic $O(a)$ improvement is preserved for maximally Wilson twisted mass fermions in the presence of such terms.

Contact terms arise in lattice correlators when two or more (pseudo)scalar densities are at the same space-time point and generate short-distance singularities that can spoil this automatic $O(a)$ improvement, i.e. introduce $O(a)$ cut-off effects in physical correlators. Working in the framework of the Operator Product Expansion and using the symmetries of our setup, we have shown that the additional terms in the Symanzik expansion that arise due to contact terms vanish at maximal twist. Thus, automatic $O(a)$ improvement is preserved, justifying the $O(a^2)$ continuum limit scaling analysis of refs. [1, 2].

We remark that our discussion holds also in the general case – for any density chain that can be written in terms of $D^\dagger D$ (i.e. containing an even number of pseudoscalar and scalar densities). For a discussion concerning the automatic $O(a)$ improvement of the hadronic vacuum polarization function, we refer to Ref. [21].

Acknowledgments

For the analysis carried through in this paper discussions with Andrea Shindler have been instrumental and we gratefully acknowledge his significant help and the development of the strategy for the proof of $O(a)$ improvement presented in this paper. We also thank Vincent Drach, Gregorio Herdoiza, Alberto Ramos and Giancarlo Rossi for useful discussions and Marcus Petschlies for carefully reading the manuscript. This work has been supported in part by the Foundation for Polish Science fellowship “Kolumb” and by the DFG Sonderforschungsbereich/Transregio SFB/TR9.
