ABSTRACT

Background: Maternal and child health are critically important in a country that is experiencing high infant mortality and maternal mortality. Research all over the world has suggested that one of the major solutions to this problem is availability of Emergency Obstetric Care services within the reach of people. Objectives of the study were to examine profile of mothers who have delivered in health facility during a year and the interplay of various factors in child birth and newborn outcome.

Methods: Retrospective cross sectional study conducted by collecting information in predesigned format from medical records. Appropriate statistical methods and test of significance performed for qualitative and quantitative variables.

Results: Out of 539 women, the majority of 42.9% were in the age group 20-25 years, the mean age (SD) of mother was 24.1 years (±4.09). Out of total 539 vaginal deliveries, 56.6% cases episiotomy was performed. 41.6% deliveries occurred from 8 AM to 4 PM. The mean birth weight was 2.830 kg SD 0.439 and low birth prevalence 16.0%. Parity with time to delivery after admission in different age groups revealed significant association (X²=66.456, p=0.000). Women aged less than 20 years are 12 times more at risk of episiotomy performed. The multivariate logistic regression analysis shows 60.67% specificity and 85.59% sensitivity in predicting episiotomy.

Conclusions: From study it is evident that women report to hospital late in labor hence there is urgent need to provide quality antenatal care services at village and PHC level and augment awareness among the community for promotion of safe motherhood.

Keywords: Safe motherhood, PHC, Obstetric care

INTRODUCTION

Every year more than 200 million women become pregnant. Most pregnancies end with the birth of a live baby to a healthy mother. But because of difficulties associated with human birth, women often require assistance during delivery. With the global phenomenon of increasing urbanisation many more women are delivering in obstetric facilities, whether they are having normal or complicated births. Generally, between 70 and 80% of all pregnant women may be considered as low-risk at the start of labour. Around 15% of all pregnant women will develop a potentially life-threatening complication that calls for skilled care, and some will require a major obstetrical intervention to survive. The problems of maternal and neonatal mortality are complex, involving women’s status, education, employment opportunities and the availability to women of basic human rights and freedoms.

In 1988, following an influential call for action, the Safe Motherhood movement was launched in Nairobi, Kenya.
During the 1990s, there was a major reversal in policy, with WHO and other UN agencies strongly discouraging the use of traditional birth attendants and exclusively promoting facility births with skilled attendants. The basic 4 pillars of safe motherhood such as family planning, antenatal care, clean/safe delivery, essential obstetric care must be delivered through primary healthcare and rest on a foundation of greater equity for women (Figure 1).

**Methods**

**Study design**

Cross sectional retrospective study.

**Study setting**

24×7 primary health center (PHC) of Hailakandi district of Assam, India. Out of four Block PHCs, one was selected conveniently. The PHC cover a population 46,000 is rendering 24×7 delivery services and having a functioning Newborn care Corner (NBCC), operational referral services, good record keeping and manpower posted in the labour room who are trained on Skill birth attendant (SBA), basic emergency obstetric care (BEmoC), Navajatkal Shishu suraksha Karyakram (NSSK) training. There are 3 Medical Officers, 5 staff nurses, 3 Auxillary nurse midwives (ANMs) who provides round the clock duties.

**Study period**

1 year (1st April 2016-31st March 2017).

**Study sample**

Consecutive 539 women delivered in the facility.

**Exclusion criteria**

Referred cases having obstetric complication were excluded.

**Method of data collection**

Data was collected in a predesigned format by referring to the delivery register and bed head tickets for all delivered cases occurred during the study period and whereby necessary by interacting with the attending MO and GNMs in labour room.

**Statistical analysis**

Data was then entered in excel sheet and analyzed by using SPSS statistical package 16.0 version. Results were presented in tables and graphs. Qualitative and Quantitative data was expressed as percentage, mean, standard deviation respectively, suitable test of significance performed like chi square test, ANOVA, logistic regression.

Due approval from ethical committee of the institute was obtained before undertaking the study and also permission from district health authority and PHC in-charge was taken.
RESULTS

Mother characteristics

Out of 539 women, the majority of 42.9% were in the age group 20-25 years followed by 32.5% in 25-30 years age group. The mean age (SD) of mother was 24.1 years (±4.09) and median age was 24 years (Range 40-16 years). 67.7% of women multiparous, of whom 76.7% have children 1–2 nos. the maximum number of living children women having was 7. The mean age (SD) of multipara women 26 years (3.79) (Range -20-40 years] whereas for primipara it is 21 years (2.80) [Range -16-32 years] The sex ratio among the living children was 844 males per 1000 females. Majority (59.8%) of study population belonged to Muslim religion (Table 1).

Table 1: Mother characteristics.

| Age group (yrs) | Number (n=539) | % |
|----------------|----------------|---|
| <20           | 57             | 10.57 |
| 20-25         | 231            | 42.86 |
| 25-30         | 175            | 32.47 |

| Multipara       | 365            | 67.72 |

| Religion        | Number (n=539) | % |
|-----------------|----------------|---|
| Hindu           | 217            | 40.26 |
| Muslim          | 322            | 59.74 |

| No living children† | Number (n=539) | % |
|---------------------|----------------|---|
| Nil                 | 32             | 8.77 |
| 1-2                 | 280            | 76.71 |
| 3                   | 30             | 8.22 |
| ≥4                  | 23             | 6.30 |

†Note: out of 365 multiparous women 32(8.77%) not having living children.

Table 2: Mode and time of delivery and deliver outcome.

| Mode of delivery          | Number (n=539) | %   |
|---------------------------|----------------|-----|
| SVD with episiotomy       | 305            | 56.59 |
| SVD                       | 234            | 43.41 |

| Time of delivery          | Number (n=539) | %   |
|---------------------------|----------------|-----|
| 8 AM-4 PM                 | 224            | 41.56 |
| 4 PM-8 PM                 | 86             | 15.96 |
| 8 PM-00 AM                | 82             | 15.21 |
| 00 AM-8 AM                | 147            | 27.27 |

| Delivery outcome (n=540)  | Number (n=539) | %   |
|---------------------------|----------------|-----|
| Sex: Male                 | 256            | 48.30 |
| Female                    | 274            | 51.70 |
| <2.5 kg                   | 85             | 16.04 |
| ≥2.5 kg                   | 445            | 83.96 |
| Still births              | 10             | 1.85 |

As per availability of level 2 facility care all women had vaginal deliveries. In 56.6% cases episiotomy was performed. Majority (41.6%) deliveries occurred from 8 AM to 4 PM. The details of outcome of deliveries are given in Table 2.

Delivery outcome

Newborn birth weight

Of the total 530 live born babies 48.30% were boys and 51.70% females (Table 2). Overall mean birth weight was 2.830 kg SD 0.439 [Range 1.1 kg-4 kg]. The prevalence of low birth weight in the present study was found to be 16.04%.

Association of newborn birth weight with sex of baby

The mean birth weight for boys was 2.858 kg and SD 0.438 kg while for girls was 2.803 kg and SD 0.440 kg. The difference of mean birth weights between sex was found not significant (F=2.076; p=0.150). The LBW prevalence among boys and girl child was 18.06% and 19.65% respectively. However, the difference was not significant (p=0.723).

Association of Mean mother age, Parity, Birth weight, episiotomy in different age groups

From Table 3, mean age of mother and parity in different age groups was found to be statistically significant.

Association of time to delivery after admission in relation to age of mother and parity

Analysis of parity with time to delivery after admission in different age groups revealed significant association (X²=66.456, p=0.000) (Figure 2).

Figure 2: Time to delivery percent distribution among the nullipara and multiparous mothers in different age groups.
The time to delivery after admission was more than 24 hours in 40.6% of mothers who are primipara and in the age group less than 20 years while 68.7% of multiparous mothers in age group 21-30 years delivered within 2 hours of admission which signifies delay in reporting to hospital.

Association of episiotomy performed with age of women

The women less than 20 years was 12 times more at risk of performing episiotomy compared to more than 20 years age group (Odds ratio=12.09, 95% Confidence interval=4.30 to 33.93, p<0.0001).

Table 3: Mean mother age, parity and birth weight in different age groups.

| Maternal age | <20 | 20-24.9 | 25-29.9 | 30-34.9 | >35 | P* |
|--------------|-----|---------|---------|---------|-----|----|
| n            | 57  | 231     | 175     | 61      | 15  |    |
| Mother age in years Mean (SD) | 18.8 (0.6) | 21.8 (1.4) | 26.3 (1.3) | 30.8 (1.3) | 35.9 (1.6) | 0.000 |
| Parity       |     |         |         |         |     |    |
| Multi        | -   | 132 (57.1) | 162 (92.6) | 56 (91.8) | 15 (100.0) | 0.000 |
| Nulli        | 57  (100.0) | 99 (42.9) | 13 (7.4) | 5 (8.2) | -   |    |
| Baby birth weight mean (SD) | 2.7 (0.4) | 2.8 (0.4) | 2.9 (0.4) | 2.9 (0.4) | 2.7 (0.5) | 0.004 |
| Episiotomy   | 53  (93.0) | 159 (68.8) | 72 (41.1) | 18 (29.5) | 3 (20) | 0.000 |

Note: * for continuous variable ANOVA and categorical chi square test done.

Table 4: Predictors of SVD* with episiotomy.

| Variable | B    | S.E.  | Wald | df  | Sig  | Exp (B) | 95% CI for EXP(B) |
|----------|------|-------|------|-----|------|---------|------------------|
|          |      |       |      |     |      |         |                  |
| Age      | 0.115| 0.030 | 14.368 | 1   | 0.000| 1.122   | 1.057, 1.190     |
| Parity   | 2.600| 0.351 | 54.819 | 1   | 0.000| 13.460  | 6.763, 26.787    |
| B Wt     | -0.129| 0.241 | 0.285 | 1   | 0.593| 0.879   | 0.548, 1.410     |
| Constant | -4.759| 0.943 | 25.471 | 1   | 0.000| 0.009   |                  |

Note: Hosmer and Lemeshow test show significance at 0.518 hence the model is acceptable. Abbreviation-SVD- Spontaneous vaginal delivery.

Logistic regression analysis

Logistic regression analysis was done with the predictor variables age, parity of mother and newborn birth weight to predict spontaneous vaginal delivery (SVD) with episiotomy. The regression model with intercept only can predict 56.71% but inclusion with these variables helped to improve predictability up to 71.46%. Employing 0.5 criteria of statistical significance the result are tabulated in Table 4. By using the regression model there is 60.67% specificity and 85.59% sensitivity in predicting episiotomy.

DISCUSSION

The overall prevalence of institutional births in rural India has increased from 15% in 1989 to 25% in 1998 and presently 78.9% and in public health facilities 52.1% (NFHS 4, 2015-16) following launch of NRHM in 2005 and implementation of maternal health promotion schemes specially JSY Scheme.14 The present study reveals profile of mothers delivering at Primary health center of Assam, India and related associated factors.

Mother characteristics and newborn outcome

In the present study the mean age (SD) of mother was 24.1 years (±4.09) range 16-40 years, similar mean maternal age of mother of 23.9±4.0 years (range: 18-40 years) reported from a hospital based study conducted in Madhya Pradesh.15 Comparatively, present study shows lower 10.6% and 2.8% women were below the age of 20 years and above 35 years of age (Table 1) while in the same study this was 17.5% and 5.1% respectively while higher 37.6% and 3.1% reported from Andhra Pradesh.13,17 However, a lower overall mean (SD) age of mother 21.7 years (3.44 years) was observed in a hospital based study conducted in Kolkata among the mothers who had normal delivery.16

In the present study 32.3% women were Primipara and 67.7% multipara (Table 1) which is similar to findings from Madhya Pradesh 37.9% and 62.1% respectively and Andhra Pradesh in contrast to this the study from Kolkata found 55.9% women were primipara and 44.1% multipara.15,17

The present study observed 48.3% newborn were boys and 51.7% girls and overall mean (SD) birth weight 2830 gram (0.439), in contrast to this, 53.8% boys and 46.2% were girls and lower average birth weight 2592 g (371 g) was recorded from South Kolkata and 58.8% boys and 41.2% girls, 50.4% boys and 49.6% girls.14,16,17 The present study prevalence of LBW 16% is much lower than other studies from India.15,17 This is observed because of improved antenatal services, ASHA services
and additional support in high priority districts and increasing awareness among the community.

A higher rate of episiotomy (56.6%) is observed in the present study compared to 26.1% as reported from Andhra Pradesh. Similar to present finding mother age, parity was found as predictor of episiotomy with vaginal delivery in a study in Nigeria. However age of women was not found predictor for episiotomy in primigravida. Similar to present finding, birth weight was not a significant factor for episiotomy this could be because most macrosomic babies were delivery by women who were multiparous.

The present study shows proportion of delivery during 4 PM–8 PM 16% is similar 17% to study conducted at Harare Maternity Hospital, Harare, Zimbabwe. However higher 41.6%, 34% and 27.3% is observed in the present study during time period 8 AM–4 PM, 8 PM–12 AM and 12 AM–8 AM compared to 31%, 15.2% and 18% in the other study.

CONCLUSION

The escalation in institutional births, referral and newborn care and provision of additional support in high priority district has invited more qualitative obstetric care at PHC level. From present study it is evident that women report to hospital late in labor and child birth less than 20 years of age results to higher morbidity to both mother and newborn. There is urgent need to provide quality antenatal care services at village and PHC level and augment awareness among the community for promotion of safe motherhood.

Limitation of study

The present study being a retrospective study could not elicit association of other variables such as socio-demographic, antenatal, previous pregnancy history and health seeking behavior of the population studied. Further prospective study is necessary to corroborate present findings.
