(October 22, 2018)

Some years ago it was shown by Ma that in the context of the electroweak standard model there are, at the tree level, only three ways to generate small neutrino masses by the see-saw mechanism via one effective dimension-five operator. Here we extend this approach to 3-3-1 chiral models showing that in this case there are several dimension-five operators and we also consider their tree level realization.

PACS number(s): 12.60.-i, 14.60.Pq

I. INTRODUCTION

Although recent data on neutrino oscillation experiments [1–3] strongly suggest that neutrinos have nonzero small masses the issue of explaining its tiny value is still an open question. Several years ago it was noted by Weinberg [4] and independently by Wilczek and Zee [5], that the neutrinos may acquire naturally small Majorana masses through dimension-five effective operators like

\[ \overline{\nu}_{aL}^c l_{jbl}^a \Phi_k^{(m)} \Phi_l^{(n)} (f_{abmn} \epsilon_{ik} \epsilon_{jl} + f'_{abmn} \epsilon_{ij} \epsilon_{jl}), \]  

(1)

being the couplings \( f \) and \( f' \) of the order of \( \Lambda^{-1} \), where \( \Lambda \) is a large effective mass related to new physics. When the neutral component of the scalar doublet \( \Phi \) develops its vacuum expectation value (VEV), \( \langle \phi \rangle \), it will produce the following mass matrix for the neutrinos

\[ M_\nu = \frac{f \langle \phi \rangle^2}{\Lambda}, \]  

(2)

and since \( \langle \phi \rangle \) is of the order of 100 GeV, small Majorana neutrino masses are generated if \( \Lambda > 10^{13} \) GeV.

The interesting point in Eq. (2) is that the lightness of the neutrino masses are generated via new physics at an energy scale \( \Lambda \gg G_F^{-1/2} \). This is the usual see-saw mechanism [6]. The realizations of that operator inside the standard model (SM) were already investigated by Ma in Ref. [7]. There it was sketched all the ways such operator can be realized at the tree and one loop level. Although it was noted in the early references [4,5] that it is necessary to renormalize these effective operators, we will not address this issue here [5].

The outline of this work is the following. In section II we review the several ways to generate such sort of operators in the context of the standard model. In section III we consider the generation of those operators in the 3-3-1 model. Our conclusion will appear in section IV.

II. SEE-SA W TREE LEVEL REALIZATION IN THE STANDARD MODEL

In the context of the standard model with only the lepton doublets \( \Psi_{aL} = (\nu_{aL}, l_{aL})^T \), \( a = e, \mu, \tau \), and a scalar doublet \( \Phi = (\phi^+, \phi^0)^T \), there are only three possibilities for implementing naturally small neutrino masses with dimension-five effective operators [7]. On the other hand, if we add new leptons a new possibility arises. They are the following:

I) \( \Psi_{aL} \) and \( \Phi \) form a fermion singlet, so that the effective interaction is

\[ \overline{\nu}_{aL}^c l_{jbl}^a \Phi_k^{(m)} \Phi_l^{(n)} (f_{abmn} \epsilon_{ik} \epsilon_{jl} + f'_{abmn} \epsilon_{ij} \epsilon_{jl}), \]  

(1)

being the couplings \( f \) and \( f' \) of the order of \( \Lambda^{-1} \), where \( \Lambda \) is a large effective mass related to new physics...
\[ \mathcal{L}_{1F}^{eff} = \frac{f_{ab}}{\Lambda} \left[ (\bar{\Psi})^{\dagger}_{aR} \Phi |e(\Psi^c)_{bR} \Phi| + H.c. \right] \\
= \frac{f_{ab}}{\Lambda} \left[ (\bar{\nu})^{\dagger}_{aR} \phi^0 - (\bar{\nu})_{aR} \phi^+ \right] \left( \nu^0_{bL} - l^0_{bL} \phi^+ \right) + H.c., \]

(3)

e denotes the antisymmetric SU(2) tensor and we have suppressed SU(2) indices. The tree level realization of this effective operator is achieved by the introduction of one or more neutral right-handed singlets, say \( N_{aR} \), which produces the usual see-saw mechanism [14], and it is linked to the standard left-handed neutrinos through the interaction

\[ f_{ab} \bar{\Psi}_{aL} \bar{\Phi} N_{bR} + H.c., \]

(4)

with \( \bar{\Phi} = i \tau^2 \Phi^* \), this interaction and the bare mass term for \( N_{aR} \), \((N_{aR})^T M_{Rab} N_{bR}\), leads to the following Dirac-Majorana matrix

\[ \begin{pmatrix} 0 & M_D^T \\ M_D & M_R \end{pmatrix}, \]

(5)

in the basis \((\nu_L, (N_R)\nu)^T\). The matrix above, after diagonalization, gives the following expression for the neutrino masses:

\[ M_\nu = M_D^T M_R^{-1} M_D. \]

(6)

From Eq. (6) we recover Eq. (3) by choosing \( M_D = f(\phi) \) and taking \( M_R = \Lambda \), obtaining in this way the canonical see-saw mechanism, or the now called type I see-saw [3], which is the usual realization of the effective operator in Eq. (3) found in literature. Notice that the see-saw here is a relation among fermion masses and \( N_R \) could be the right-handed neutrinos \( \nu_R \). Its realization is depicted in Fig. 1 with the replacements \((\nu)_{ab} \rightarrow (\nu)_{ab} \equiv f_{ab}(\xi)\) and \( (\bar{\Psi})_{aL} \rightarrow (\bar{\Psi})_{aL} \). \( \Xi \) and the usual leptons, \( \Psi_{aL} \) and \( \Psi_{bL} \) form a scalar triplet with the effective interaction

\[ \mathcal{L}_{3S}^{eff} = \frac{f_{ab}}{\Lambda} \left( \bar{\Psi}_{aL} \bar{\Phi} (\psi^c \cdot e) \Phi + H.c. \right) \\
= \frac{f_{ab}}{\Lambda} \left( (\bar{(\nu)})_{aR} \nu^0_{bL} \phi^0 \right) - 2 \phi^0 \phi^+ (\bar{\nu}^0_{aR} b_L + \bar{\nu}^0_{aR} b_L) \]

+ \bar{\nu}^0_{aR} b_L \phi^+ \phi^+ | + H.c.. \]

(7)

The tree level realization in this case is obtained by introducing a complex (\( Y = 2 \)) scalar triplet \((\xi^+, \xi^+, \xi^0)\) or, in matrix notation [14,15]

\[ \mathcal{\bar{\xi}} \cdot \Xi = \begin{pmatrix} \xi^+ \\ \sqrt{2} \xi^0 \\ -\xi^+ \end{pmatrix}. \]

(8)

In this case we have the interaction between the triplet \( \Xi \) and the usual leptons,

\[ f_{ab} \bar{\Psi}_{aL} (\mathcal{\bar{\xi}} \cdot \Xi) \Psi_{bL} + H.c. \]

(9)

From the expression above \( \Xi \) must carry two units of lepton number. After the triplet develops a VEV the neutrinos gain masses which are given by the following expression:

\[ M_{\nu_{ab}} = f_{ab} \langle \xi^0 \rangle. \]

(10)

Differently from the type I see-saw mechanism where the suppression must come from \( \langle \xi^0 \rangle \equiv \langle \xi \rangle \). For this we have to study the scalar potential of the model. The complete scalar potential composed by the standard Higgs doublet \( \Phi \) and the triplet \( \Xi \) is:

\[ V(\phi, \xi) = \mu^2_\phi \Phi^\dagger \Phi + \mu^2_\Xi \Xi^\dagger \Xi + \lambda_\phi (\Phi^\dagger \Phi)^2 + \lambda_\Xi (\Xi^\dagger \Xi)^2 \]

\[ + \lambda_{\phi \Xi} \Xi^\dagger \Xi \Phi^\dagger \Phi + M_\Xi \Phi^T \Xi \Phi, \]

(11)

where the last term breaks explicitly the lepton number. The stationary conditions for this potential gives the following constraint equations:

\[ \langle \phi \rangle \left( \mu^2_\phi + \lambda_\phi \langle \phi \rangle^2 + \lambda_{\phi \Xi} \langle \xi \rangle^2 \right) = 0, \]

\[ \langle \xi \rangle \left( \mu^2_\Xi + \lambda_\Xi \langle \xi \rangle^2 + \lambda_{\phi \Xi} \langle \phi \rangle^2 \right) = 0. \]

(12)

Assuming that \( |\mu_\xi| \sim M_\xi \gg \langle \phi \rangle \), with \( \mu_\xi^2 < 0 \), the second constraint equations provides the following relation between the vacua of the model:

\[ \langle \xi \rangle \sim \frac{\langle \phi \rangle^2}{M_\xi}. \]

(13)

Substituting Eq. (13) in Eq. (11) we get the see-saw mass relation for neutrinos,

\[ M_{\nu_{ab}} = \frac{f_{ab} \langle \phi \rangle^2}{M_\xi}. \]

(14)

If the triplet \( \xi \) belongs to some GUT, we can recognize \( M_\xi \) as the high scale \( \Lambda \). This is the so called type II see-saw mechanism [16]. Notice that in this type of see-saw a very heavy scalar could develop a very tiny vacuum [17], differently of the type I see-saw where a very heavy right-handed neutrino induces tiny mass to the light neutrinos. The tree level realization of this mechanism is shown in Fig. 2. \( \Phi \) and \( \Xi \) form a fermion triplet with \( Y = 0 \) and the effective Lagrangian is then written as:

\[ \mathcal{L}_{3F}^{eff} = \frac{f_{ab}}{\Lambda} \left[ (\bar{(\nu)})_{aR} \cdot \Phi \right] |e(\Psi^c)_{bL} \cdot e\Phi| + H.c. \]

\[ = \frac{f_{ab}}{\Lambda} \left[ (\bar{\nu}^0_{aR} b_L \phi^+ \phi^0) - (\bar{\nu}^0_{aR} b_L \phi^0) + \bar{\nu}^0_{aR} b_L \phi^+ \phi^0 \right] \]

+ \bar{\nu}^0_{aR} b_L \phi^+ \phi^+ | + H.c.. \]

(15)

In this case, the tree level realization is based on the introduction of the \( Y = 0 \) triplet of leptons [18]:

\[ \mathcal{\bar{\xi}} \cdot \tilde{\Delta}_L = \left( \begin{array}{c} N \\ \sqrt{2} P^- \end{array} \right). \]

(16)

This triplet is linked to the standard model content by the interaction
\[ f_a \left[ \bar{\Phi}^T \vec{\tau} \cdot \Delta_L (\Psi_{aL})^c + \Phi^T (\vec{\tau} \cdot \Delta_L)^c \Psi_{aL} \right] + H.c., \] (17)

where \( \Phi = e \Phi^* \). The interaction in Eq. (17), together with the mass term \( M_\Delta (\Delta_L)^T \Delta_L \), yields the mass matrix, in the basis \((\nu_{aL}, N_L)_I^T\),

\[ \begin{pmatrix} 0 & M_L \\ M_L & M_\Delta \end{pmatrix}. \] (18)

Notice that in this case \( M_{aL} = f_a \langle \phi \rangle \) is not an arbitrary mass matrix, hence, after diagonalization, two neutrinos are massless and two have non-zero masses at the tree level. One of the massive neutrinos has a mass proportional to \( M_\Delta \) and the other one \( \sim f_a \langle \phi \rangle^2 / M_\Delta \) [18]. Although this is also a see-saw relation we see that the neutrino mass spectrum is different from that of the general see-saw mechanism, since two of them are massless at the tree level. Notice also that the interactions in Eq. (17) violate explicitly the lepton number. This is the third possibility of realization at the tree level of the effective dimension-five operator that leads to a see-saw relation for the neutrino masses. Even though it leads to the same see-saw relation, as the last two most explored mechanisms explicated in I) and II), this mechanism has not been widely appreciated in literature. It is depicted in Fig. 1 with \( N_R \) replaced by \( (N_L)^c \).

An interesting version of the model in which we obtain a general see-saw mass matrix is the one where we identify \( N_L \) as being \( (\nu^c)_L \) and add three triplets \( \Delta_{aL}, a = e, \mu, \tau \); since in this case \( M_L = f_{ab} \langle \phi \rangle \), we can have a neutrino mass matrix as in Eq. (2) in the canonical see-saw mechanism.

Unlike the other two types of see-saw mechanisms, in the present one we must verify if this fermion triplet \( \Delta \) does not lead to any implication in the charged lepton masses. The general mass matrix in the charged lepton sector is rather complicated since the interactions in Eq. (17) together with the standard Yukawa interaction \( \lambda \Psi_a \Phi \Omega \) lead to the following charged lepton matrix in the basis \((l_L, P_L)_I^T\):

\[ (l_L, P_L) \begin{pmatrix} M_D & M_L \\ 0 & M_\Delta \end{pmatrix} \begin{pmatrix} i_R \\ P_R \end{pmatrix}, \] (19)

where \( M_{Dab} = \lambda_{ab} \langle \phi \rangle \). With \( M_{aL} = f_{a} \langle \phi \rangle \) (or \( M_L = f_{ab} \langle \phi \rangle \) if we add triplets) we see that the mass matrix in Eq. (19) can be only easily diagonalized if we assume that \( M_D \) is diagonal. For more details see Ref. [18].

\[ \textbf{IV) } \] However, if we extent the particle content of the standard model, another possibility is that \( \Psi_{aR} \) and \( \Phi \) form a non-Hermitian fermionic triplet with \( Y = 2 \). In this case, although it is not possible to build an effective operator of the form given in Eq. (17), we can introduce a fermionic non-Hermitian \( (Y = 2) \) triplet \( \Omega = (\omega^+, \omega^+, \omega^0) \) or

\[ \vec{\omega} \cdot \Omega = \begin{pmatrix} \omega^+ & \sqrt{2} \omega^{++} \\ -\sqrt{2} \omega^0 & -\omega^+ \end{pmatrix}^T, \] (20)

so that we have the interactions

\[ f_a \left[ \bar{\Phi}^T \vec{\tau} \cdot \Omega_L (\Psi_{aL})^c + \Phi^T (\vec{\tau} \cdot \Omega_L)^c \Psi_{aL} \right] + H.c., \] (21)

which together with a mass term \( M_\Omega (\Omega^c)_R \Omega_L \) give a mass matrix of the form in Eq. (16) with \( M_R \rightarrow M_\Omega \).

Next, we introduce the right-handed doublets as \( \psi_{aR} = (N, E^-)_a \sim (2, -1) \), and so it is possible to have

\[ \mathcal{L}_{\text{eff}}^f = f_{ab} \frac{v}{\Lambda} \left( \bar{\Psi}_{aL} \cdot \Phi \right) \left( \psi_{bR} \cdot \bar{\Phi} \right) + H.c. \] (22)

Notice that, even if the first three ways of realization of the effective dimension-five operator at tree level are very different, in the end the neutrino masses receive the same expression in the form of the see-saw relation presented in Eq. (4). In the fourth way it is also possible to generate such a mass matrix but only at the tree level if we do not restrict ourselves to the usual leptonic representation content. The only context in which they can be distinguished is by their consequences at high energy once the type I see-saw favors SO(10) and type II and III favor SU(5) in 15 and 24 representation respectively. In fact, the first one has been more studied in the literature and it was in this context that the see-saw mechanism was proposed [3]. The scalar triplet has also been largely considered in literature [14]. Both alternatives can be implemented more naturally in the context of the standard model or in some of its extensions since, for instance, the introduction of neutral singlets leaves the model more symmetrically relative to quarks and leptons, or because the scalar representation content is not constrained by the gauge invariance. This is not the case with the lepton triplet. However, recently it has been shown that in a 3-3-1 supersymmetric model [13] there is a fermionic non-hermitian triplet under the 3-2-1 symmetry that is part of a sextet of higgsinos transforming as \( (6, 0) \) under \( SU(3)_L \otimes U(1)_N \).

\section{III. The Effective Dimension-Five Operator and Its Realization in 3-3-1 Chiral Models}

In this section we build the effective dimension-five operator in the context of 3-3-1 chiral models and its realizations at the tree and the 1-loop level. We employ the same approach used for the realizations of Eq. (2) in the SM outlined in the last section. As in the SM, in the minimal 3-3-1 model [8], or in some of its extensions [2], neutrinos are strictly massless due to the conservation of the total lepton number. In these models all leptons come only in triplets. In one version of this model, to generate the mass of all the particle content of the model, three triplets \( \eta, \rho, \chi \) and a sextet \( S \) of scalars are required.

We have at least two triplets, the leptonic one \( \Psi_{aL} = (\nu_{aL}, l_{aL}, l_{cL})^T \) and the scalar one \( \eta = (\eta^+ \eta^- \eta^0)^T \),
both transforming like \((3, 0)\) under the electroweak gauge symmetry \(SU(3)_L \otimes U(1)_Y\). Hence, we can form bilinears like \(\Psi \eta = 3 \otimes 3 = 1_A \oplus 8\) or \(\Psi \eta = 3 \otimes 3 = 3_A \oplus 6_S\). In this case we will have the following possibilities for the effective interactions:

A) \(\Psi\) and \(\eta\) form a fermion singlet, and the effective operator is written as

\[
\mathcal{L}_{\text{ eff}}^{\Psi \eta} = \frac{f_{ab}}{\Lambda} [\eta^i (\Psi^a_R)^\dagger \eta^j \Psi^b_L] + \text{H.c.}
\]

\[
= \frac{f_{ab}}{\Lambda} (\tilde{\nu}^c_{aR} \eta^{0^c} + \tilde{\nu}^c_{aR} \eta^{1^c} + \tilde{\nu}^c_{aR} \eta^{2^c}) \eta_{iL} \eta^{0^i} + \eta_{iL} \eta^{1^i} + \tilde{\nu}^c_{aR} \eta^{0^c} + \tilde{\nu}^c_{aR} \eta^{1^c} + \tilde{\nu}^c_{aR} \eta^{2^c}) + \text{H.c.} \quad (23)
\]

At the tree level we can realize this situation by introducing again one or more neutral fermion singlets, \(N_{bR}\)'s, and it is also a realization of the usual see-saw mechanism. This is in fact equivalent to the case I in the previous section. Like there the intermediate heavy particle here should be a right-handed neutrino, \(\nu_R\). The realization of this operator with \(\nu_R\) is similar to that in Fig. \(\text{III}\) with \(\langle \phi \rangle\) replaced by \(\langle \eta \rangle\). The heavy right-handed neutrinos are linked with \(\nu_L\) by a term like this one:

\[
f_{ab} \bar{\Psi}^a_{aL} \eta \bar{\nu}_b + \text{H.c.}, \quad (24)
\]

which together with the mass term \(M_{R} \bar{\nu}_b \nu_R\) leads to the mass matrix defined in Eq. \(\text{I}\) in the basis \((\nu_L, (\nu_R)^\tau)\) with \(M_{ab} = f_{ab} \langle \eta \rangle\).

B) Next, we can form with \(\Psi_{aL}\) and \(\eta\) an octet of leptons if we define the traceless matrix,

\[
M_{aI} = (\Psi^a_{aiR}) \eta^{ij} - \frac{1}{3} \delta^i_j \langle (\Psi^a_{aiR}) \eta^{ij} \rangle, \quad (25)
\]

where \(i, j\) denote \(SU(3)\) indices. The effective interaction is in this case given by

\[
\mathcal{L}_{\text{ eff}}^{\Psi \eta} = \frac{f_{ab}}{\Lambda} \:	ext{Tr}(\tilde{M}_a M_b) + \text{H.c.}
\]

\[
= \frac{f_{ab}}{\Lambda} \left[ \frac{1}{9} (2 \tilde{\nu}^c_{aR} \eta^{0^c} - \tilde{\nu}^c_{aR} \eta^{1^c} - \tilde{\nu}^c_{aR} \eta^{2^c}) (2 \nu_{bL} \eta^{0^b} - \nu_{bL} \eta^{1^b} - \nu_{bL} \eta^{2^b}) + \tilde{\nu}^c_{aR} \nu_{bL} (\eta^{0^c} \eta^{0^b} + \eta^{1^c} \eta^{1^b} + \eta^{2^c} \eta^{2^b})
\right.
\]

\[
+ \tilde{\nu}^c_{aR} \nu^{R} \eta^{0^c} + \nu^{R} \eta^{1^c} + \tilde{\nu}^c_{aR} \nu^{R} \eta^{0^c} + \tilde{\nu}^c_{aR} \nu^{R} \eta^{1^c} + \tilde{\nu}^c_{aR} \nu^{R} \eta^{2^c} + \tilde{\nu}^c_{aR} \nu^{R} \eta^{2^c} - \tilde{\nu}^c_{aR} \nu^{R} \eta^{0^c} - \tilde{\nu}^c_{aR} \nu^{R} \eta^{1^c} - \tilde{\nu}^c_{aR} \nu^{R} \eta^{2^c} + \text{H.c.}\] \quad (26)

Hence we need a heavy fermion octet transforming as \((1, 8, 0)\) under the 3-3-1 factors,

\[
H_L = \begin{pmatrix}
N_1^+ & P_1^+ & P_2^+ \\
N_2^+ & N_2 & X_2^0 \\
P_1^- & X_1^0 & N
\end{pmatrix}_L,
\]

where \(N = -N_1 - N_2\). We have the interaction

\[
f_{a}[(\Psi_{aL})^c H_L \eta + \eta^\dagger (H_L)^c \Psi_{aL}] + \text{H.c.}, \quad (28)
\]

omitting \(SU(3)\) indices. There is also the bare mass term \(M_H (H_L)^c H_L\). These interactions produce a mass matrix for the neutrino sector like that in Eq. \(\text{I}\), but now with \(M_{ab} = f_{ab} \langle \eta \rangle\) and \(M_{ab} \rightarrow M_H\). Two neutrinos remain massless and two gain masses. The tree level realization of this mechanism can be seen in Fig. \(\text{III}\) with \(N_R\) replaced by \((N_{1,2L})^c\) and \(\langle \phi \rangle\) replaced by \(\langle \eta \rangle\). However, if we introduce three of such octets and identify, say \(N_{1aL}\) with \((\nu^c)^{aL}, a = e, \mu, \tau\), we can generate a general see-saw mass matrix like in Eq. \(\text{I}\) since now \(M_{Lab} = f_{ab} \langle \eta \rangle\). Notice that although this case is the analog of the case \(\text{III}\) in the previous section, i.e., an hermitian, \(Y = 0\), fermion triplet; it is also a realization of the case \(\text{IV}\) where there is a non-Hermitian, \(Y = 2\), fermion triplet under \(SU(2)_L \otimes U(1)_Y\).

As in the case of the leptonic triplet in the standard model, the mass matrix of the charged lepton sector is complicated. Let us assume, for simplicity, that the mass matrix of the standard charged leptons, generated at low energy in the basis of the 3-3-1 symmetries, is diagonal and let us call it \(M_L\), and for the mass matrix of the charged leptons, \(P_1\) and \(P_2\), matrix \(M_H\). With these assumptions and the terms in Eq. \(\text{I}\), we have the following \(5 \times 5\) matrix in the basis \((l_L, P_{1L}, P_{2L})\):

\[
\begin{pmatrix}
M_L & M_H \\
0 & M_H
\end{pmatrix}. \quad (29)
\]

As in the case \(\text{III}\) in the previous section, the diagonalization of this matrix is complicated unless we assume that \(M_I\) is diagonal, in this case the usual leptons decouple completely from the heavy ones, being the mass matrix of the former \(M_L\) and that for the heaviest \(M_H\).

C) Finally, we have the possibility that \(\Psi_{aR}\) and \(\Psi_{bL}\) form a symmetric sextet. In this case we have

\[
\mathcal{L}_{\text{ eff}}^{\Psi \eta} = \frac{f_{ab}}{\Lambda} \frac{1}{8} (\Psi^a_{aiR} \Psi^b_{bL} \eta^{ij}) + \text{H.c.}, \quad (30)
\]

and the tree level realization is the introduction of the usual sextet \((6, 0)\). Notice that the triplet \(\epsilon_{ijk} \Psi^i \Psi^j \Psi^k\) is
not realized since the respective triplet \( \epsilon_{ilm}\eta_{lm} = 0 \). However, the symmetric sector can contribute for the masses of the charged leptons and also generate the neutrino masses by loop effects.

In this case the tree level realization requires a scalar sextet, \( S \):

\[
S = \left( \begin{array}{ccc} s' & s_{1/2} & s_{3/2} \\
\frac{s_1}{\sqrt{2}} & \frac{s_3}{\sqrt{2}} & \frac{s_{11}^-}{\sqrt{2}} \\
\frac{s_{1/2}}{\sqrt{2}} & \frac{s_{3/2}}{\sqrt{2}} & s_{11}^+ \
\end{array} \right) \sim (1, 6, 0).
\] (31)

The sextet \( S \) is linked to the leptons by the interaction:

\[
V(\eta, \rho, \chi, S) = \mu_\eta^2 \eta^\dagger \eta + \mu_\rho^2 \rho^\dagger \rho + \mu_\chi^2 \chi^\dagger \chi + \mu_S^2 Tr(S^\dagger S) + \lambda_1 (\eta^\dagger \eta)^2 + \lambda_2 (\rho^\dagger \rho)^2 + \lambda_3 (\chi^\dagger \chi)^2
\]

\[
+ (\eta^\dagger \eta) (\lambda_4 (\rho^\dagger \rho) + \lambda_5 (\chi^\dagger \chi)) + \lambda_6 (\rho^\dagger \rho)(\chi^\dagger \chi) + \lambda_7 (\rho^\dagger \eta)(\eta^\dagger \rho) + \lambda_8 (\chi^\dagger \eta)(\eta^\dagger \chi) + \lambda_9 (\rho^\dagger \chi)(\chi^\dagger \rho)
\]

\[
+ \lambda_{10} Tr(S^\dagger S)^2 + \lambda_{11} (Tr(S^\dagger S))^2 + (\lambda_{12} (\eta^\dagger \eta) + \lambda_{13} (\rho^\dagger \rho)) Tr(S^\dagger S) + \lambda_{14} (\chi^\dagger \chi) Tr(S^\dagger S)
\]

\[
+ (\lambda_{15} \epsilon^{ijk} (\chi^\dagger S) \chi \rho \eta \eta + \lambda_{16} \epsilon^{ijk} (\rho^\dagger S) \rho \eta \eta + \lambda_{17} \epsilon^{ijk} \epsilon^{ilmn} \eta \eta \eta \eta S_{im} S_{mj} + H.c.) + \lambda_{18} \chi^\dagger S S^\dagger \chi + \lambda_{19} \eta^\dagger SS^\dagger \eta + \lambda_{20} \rho^\dagger SS^\dagger \rho.
\] (34)

Here, for the sake of simplicity, we impose in the scalar potential the symmetry \( \chi \to -\chi \) in order to avoid other trilinear terms besides the one that will generate the seesaw mechanism. There are also four terms permitted by the 3-3-1 gauge symmetry which violate explicitly the lepton number, but for what concern us here we just will consider only one of them:

\[
M_{S\eta^T S^\dagger \eta}.
\] (35)

Adding this term to the potential in Eq. (34), we find the following stationary condition on the VEV of the scalar field \( s' \):

\[
\langle s' \rangle \left[ \mu_S^2 + \lambda_{10} \langle s' \rangle^2 + \left( \frac{\lambda_{12}}{2} + \frac{\lambda_{19}}{2} \right) \langle \eta \rangle^2 + \frac{\lambda_{13}}{2} \langle \rho \rangle^2 + \frac{\lambda_{14}}{2} \langle \chi \rangle^2 + (\lambda_{10} + \frac{\lambda_{11}}{2}) \langle s' \rangle^2 \right] + M_S \langle \eta \rangle^2 = 0.
\] (36)

We will consider here the case when the charged leptons gain masses, not through a sextet but via the introduction of a heavy charged lepton \( \tilde{\Psi} \). In this case the sextet can be very heavy. For instance, we can assume \( \mu_S^2 < 0 \) and that \( |M_S| \gg \langle \eta \rangle, \langle \rho \rangle, \langle \chi \rangle \), so that we have from Eq. (36):

\[
\langle s' \rangle \simeq \frac{\langle \eta \rangle^2}{M_S}.
\] (37)

which gives the following expression to the neutrino mass matrix:

\[
M_{\nu ab} = f_{ab} \frac{\langle \eta \rangle^2}{M_S}.
\] (38)

This is a see-saw mass relation and its realization is equal to that in Fig. 4 with \( \xi \) replaced by \( \langle s' \rangle \) and \( \langle \phi \rangle \) replaced by \( \langle \eta \rangle \). It is the equivalent to the type II see-saw mechanism discussed in II in the last section and in Ref. [17] where it was assumed that the sextet also gives mass to the charged leptons but the dominant energy scale is \( \langle \chi \rangle \).

A sextet like that in Eq. (31) disposes of a second neutral component, \( s \), which may contribute to the charged lepton masses when developing a VEV. However it will not give a large contribution to the charged lepton masses as we can see in the following. From its stationary condition we get the constraint equation:

\[
f_{ab} \bar{\Psi}_a S \Psi_b + H.c.
\] (32)
\[ \langle s \rangle \left[ \mu_s^2 + \lambda_{10} \langle s \rangle^2 + \left( \frac{\lambda_{12}}{2} - \lambda_{17} \right) \langle \eta \rangle^2 + \left( \frac{\lambda_{13}}{2} + \frac{\lambda_{20}}{4} \right) \langle \rho \rangle^2 + \left( \frac{\lambda_{14}}{2} + \frac{\lambda_{18}}{4} \right) \langle \chi \rangle^2 + \left( \frac{\lambda_{11}}{2} + \lambda_{10} \right) \langle s \rangle^2 \right] \\
+ \frac{\lambda_{15}}{2 \sqrt{2}} \langle \eta \rangle^2 - \frac{\lambda_{16}}{2 \sqrt{2}} \langle \eta \rangle \langle \rho \rangle^2 = 0, \]

which gives the following expression to its vacuum:

\[ \langle s \rangle \simeq \frac{\langle \eta \rangle \langle \chi \rangle^2}{\mu_s^2}. \quad (40) \]

It implies \( \langle s \rangle \ll \langle s \rangle \) which turn insignificant its contribution to the charged lepton masses in relation to other sources in low energy. Notwithstanding, in the present case the charged leptons got mass through the mixing with a heavy charged lepton \([9]\).

IV. CONCLUSIONS

We have analyzed the realization at the tree level of an effective dimension-five operator that generates see-saw masses to the neutrinos and have added a new tree level implementation of the see-saw mechanism in the context of the standard electroweak model. From our analysis we can say that all the ways of realizing such operator in the standard model can be easily implemented in the 3-3-1 model as well. In particular the case \( \text{IV} \) of Sec. II is realized in the context of the 3-3-1 model when a fermion octet is added as described in the case \( \text{B} \) in Sec. II.

Finally, we would like to mention that at the one loop level the effective operator of the sort given in Eq. (1) is also easily implemented. Two simple cases are shown in Figs. 3 and 4, but they imply an extension of the 3-3-1 model by adding a pair of exotic singlets. Only the second model is favored by phenomenology. Also we should stress that, except in case \( \text{B} \) the neutrinos and charged lepton masses share a common set of parameters which leave such scenarios interesting.
