(February 27, 2001)

Considerable excitement has been caused recently by the discovery that the binary boride system with stoichiometry MgB$_2$ is superconducting at the remarkably high temperature of 39 K$^1$. This potentially opens the way to even higher $T_c$ values in a new family of superconductors with unexpectedly simple composition and structure. The simplicity in the electronic and crystal structures could allow the understanding of the physics of high-$T_c$ superconductivity without the presence of the multitude of complicated features, associated with the cuprates. Synchrotron X-ray diffraction was used to measure the isothermal compressibility of MgB$_2$, revealing a stiff tightly-packed incompressible solid with only moderate bonding anisotropy between intra- and inter-layer directions.

These results, combined with the pressure evolution of the superconducting transition temperature, suggest a positive pressure coefficient on $T_c=1.0$ K, isotope exponent $\alpha_{T_c}=0.26$ $^7$. In addition, $T_c$ has been found to decrease with applied pressure at the rate of $-\Delta T_c/dP \sim 1.6$ K/GPa up to 1.84 GPa$^5$, again consistent with mediation of the pairing interaction by phonons. An alternative scenario derives from the fact that MgB$_2$ is hole-doped and superconductivity may be understood within a formalism developed for high-$T_c$ cuprate superconductivity$^4$. Such a theory predicts a positive pressure coefficient on $T_c$ as a result of the decreasing intraplane B-B distance with increasing pressure and appears to disagree with the experimental observations. However, the response of the system may be more complex if pressure also affects the charge transfer between the B planes and Mg and will vary depending on whether the system is in the overdoped or underdoped regime.

Here, we address the problem of the evolution of the structural properties of the MgB$_2$ superconductor with applied pressure using synchrotron X-ray powder diffraction techniques. We find that MgB$_2$ remains strictly hexagonal to the highest pressure used. The isothermal interlayer compressibility, $d\ln c/dP$ at zero pressure is only 1.4 times the value of the in-plane compressibility, $d\ln a/dP$, manifesting the anisotropic nature of the crystal structure. Nonetheless, the bonding anisotropy in this material is not as large as other quasi-2D systems like alkali-metal intercalated graphite, and the elastic properties appear only moderately anisotropic. This information is valuable in testing the predictions of competing models for the mechanism of superconductivity. The diffraction experiments in combination with the data on the pressure dependence of $T_c$ permit us to determine its variation over a wide range of unit cell volume with an initial pressure coefficient, $d(\ln T_c)/dV = 0.18$ Å$^{-3}$.

The MgB$_2$ sample used in this work was prepared, as reported in$^8$, by heating a pressed pellet of stoichiometric amounts of Mg and amorphous B for 10 hours at 700°C under an argon pressure of 196 MPa and was

MgB$_2$ adopts a hexagonal crystal structure (AlB$_2$-type, space group $P6/mmm$) which is analogous to intercalated graphite with all hexagonal prismatic sites of the primitive graphitic structure (found in hexagonal BN) completely filled and resulting in two interleaved B and Mg layers. In addition, allowing for full charge transfer from Mg to the boron 2D sheets, the latter are themselves iso-electronic with graphite.

Detailed information on the properties of MgB$_2$ is being currently rapidly accumulated. Band structure calculations clearly reveal that, while strong B-B covalent bonding is retained, Mg is ionized and its two electrons are fully donated to the B-derived conduction band. Superconductivity in MgB$_2$ is then essentially due to the metallic nature of the boron 2D sheets and the presence of strong electron-phonon interactions together with the high vibrational frequencies of the light B atoms ensure a high transition temperature$^8$. Support for such a phonon-mediated BCS-type mechanism has been provided by measurements of the boron isotope effect ($\Delta T_c=1.0$ K, isotope exponent $\alpha_B \sim 0.26)$ $^3$. In addition, $T_c$ has been found to decrease with applied pressure at the rate of $-\Delta T_c/dP \sim 1.6$ K/GPa up to 1.84 GPa$^5$, again consistent with mediation of the pairing interaction by phonons. An alternative scenario derives from the fact that MgB$_2$ is hole-doped and superconductivity may be understood within a formalism developed for high-$T_c$ cuprate superconductivity$^4$. Such a theory predicts a positive pressure coefficient on $T_c$ as a result of the decreasing intraplane B-B distance with increasing pressure and appears to disagree with the experimental observations. However, the response of the system may be more complex if pressure also affects the charge transfer between the B planes and Mg and will vary depending on whether the system is in the overdoped or underdoped regime.

Here, we address the problem of the evolution of the structural properties of the MgB$_2$ superconductor with applied pressure using synchrotron X-ray powder diffraction techniques. We find that MgB$_2$ remains strictly hexagonal to the highest pressure used. The isothermal interlayer compressibility, $d\ln c/dP$ at zero pressure is only 1.4 times the value of the in-plane compressibility, $d\ln a/dP$, manifesting the anisotropic nature of the crystal structure. Nonetheless, the bonding anisotropy in this material is not as large as other quasi-2D systems like alkali-metal intercalated graphite, and the elastic properties appear only moderately anisotropic. This information is valuable in testing the predictions of competing models for the mechanism of superconductivity. The diffraction experiments in combination with the data on the pressure dependence of $T_c$ permit us to determine its variation over a wide range of unit cell volume with an initial pressure coefficient, $d(\ln T_c)/dV = 0.18$ Å$^{-3}$.

The MgB$_2$ sample used in this work was prepared, as reported in$^8$, by heating a pressed pellet of stoichiometric amounts of Mg and amorphous B for 10 hours at 700°C under an argon pressure of 196 MPa and was
superconducting with $T_c = 39$ K. Phase purity was confirmed by powder X-ray diffraction. The high pressure synchrotron X-ray diffraction experiments at ambient temperature were performed on beamline BL10XU at Spring-8, Japan. MgB$_2$ was loaded in a diamond anvil cell (DAC), which was used for the high-pressure generation and was equipped with an inconel gasket. The diameter of the top face of the diamond culet was 1 mm, and the sample was introduced in a hole made in the gasket 0.2 mm deep and 0.4 mm diameter. Silicone oil loaded in the DAC was used as a pressure medium. Pressure was increased at room temperature and was measured with the ruby fluorescence method. The diffraction patterns were collected using an image plate detector ($\lambda = 0.49556$ Å) with 5 min exposure times. Integration of the two-dimensional diffraction images was performed with the local PIP software and data analysis with the Fullprof suite of Rietveld analysis programs [10].

Synchrotron X-ray powder diffraction profiles of MgB$_2$ were collected at pressures between ambient and 6.15 GPa. Inspection of the diffraction data indicated that the pattern could be indexed as hexagonal at all pressures. Thus the same structural model (space group P6$_3$/mmm) was employed in the refinements of all datasets [1]. The Rietveld refinements ($2\theta$ range = 7-43°) proceeded smoothly (Fig. 1), leading to values for the hexagonal ambient pressure (agreement factors: order Murnagham EOS [12]: $R_K = 5.9\%$, and $\Delta V_{wp} = 3.0646(1)$ Å, $R_B = 3.0906(2)$ Å, $\Delta V_{wp} = 36(3) \AA^3$ at ambient pressure (agreement factors: $R_{wp} = 3.9\%$, $R_B = 5.9\%$, and $a = 3.0646(1) \AA$ and $c = 3.4860(2) \AA$ at 6.15 GPa ($R_{wp} = 1.0\%$, $R_B = 7.0\%$). Fig. 2(a) shows the pressure evolution of the volume of the unit cell of MgB$_2$ together with a least-squares fit of its ambient-temperature equation-of-state (EOS) to the semi-empirical second-order Murnagham EOS [12]:

$$P = (K_0/K_0')(V_0/V)K_0' - 1$$

(1)

where $K_0$ is the atmospheric pressure isothermal bulk modulus, $K_0'$ is its pressure derivative (=d$K_0$/d$P$), and $V_0$ is the unit cell volume at zero pressure. The fit results in values of $K_0 = 120(5)$ GPa and $K_0' = 36(3)$. The extracted value of the volume compressibility, d$lnV$/d$P = 8.3(3) \times 10^{-3}$ GPa$^{-1}$ implies a stiff tightly-packed incompressible solid. The anisotropy in bonding of the MgB$_2$ structure (Fig. 2 inset) is clearly evident in Fig. 2(b) which displays the variation of the hexagonal lattice constants $a$ and $c$ with pressure. As the applied pressure increases, the ($c/a$) ratio smoothly decreases (by ~0.4% to 6.15 GPa). We described the pressure dependence of each lattice constant with a variant of eq. (1), in which $K_0$ and its pressure derivative, $K_0'$ were substituted by the individual $K_x$ and $K_x'$ ($x = a, c$) values. The results of these fits are also included in Fig. 2(b) and give: $K_a = 410(20)$ GPa, $K_a' = 13(1)$; $K_c = 292(12)$ GPa, $K_c' = 85(7)$. These values clearly reveal the diversity in bonding interactions present, with the solid being least compressible in the basal plane $ab$, in which the covalent B-B bonds lie (d$lna$/d$P = 0.0024(1)$ GPa$^{-1}$). However, the interlayer linear compressibility, d$lnV$/d$P = 0.0034(1)$ GPa$^{-1}$ is only 1.4 times larger, implying very stiff Mg-B bonding; significantly, it is considerably smaller than those of the structurally related strongly anisotropic alkali-metal intercalated graphite (cf. KC$_6$, d$lna$/d$P = 0.0206$ GPa$^{-1}$ [13]). Table 1 summarizes bond distance information at selected pressures.

The pressure coefficient of $T_c$ in MgB$_2$ is strongly negative, -d$lnT_c$/d$P \approx 0.042$ GPa$^{-1}$ [8]. It straddles the values of conventional non-cuprate $sp$- and $d$- superconductors (>0.08 and <0.02 GPa$^{-1}$, respectively), while it is more than an order of magnitude smaller than those in fulleride superconductors (0.5 GPa$^{-1}$ for K$_3$C$_{60}$ [14] and 1.0 GPa$^{-1}$ for Na$_2$CsC$_{60}$ [15]). Of course, the relevant comparison must be between the volume coefficients of $T_c$. Using the measured volume compressibility of MgB$_2$, we obtain d$(lnT_c)/dV = 0.18$ Å$^{-3}$. This is even larger than the "universal" value of alkali fullerides (0.07 Å$^{-3}$ [16]) and implies a very sensitive dependence of the superconducting properties to the interatomic distances. The results of converting the $V(P)$ data in Fig. 2(b) to $T_c(V)$ are shown in Fig. 3. Within the BCS formalism for superconductivity, $T_c \propto (\hbar \omega_{ph})^{1/2}/J$ (F), where $\hbar \omega_{ph}$ is a phonon energy, $N(\epsilon_F)$ is the density-of-states at the Fermi level, and $J$ is the electron-phonon coupling constant. Given the highly incompressible nature of the MgB$_2$ solid, it is conceivable that the pressure coefficients of both $\hbar \omega_{ph}$ and $J$ are negligible. Then, to first order, Fig. 3 reflects the modulation of $T_c$ with decreasing $N(\epsilon_F)$, which results from the broadening of the conduction band as the B-B (and the Mg-B) orbital overlap increases with increasing external pressure. Such a situation is reminiscent of the C$_{60}$-based superconductors and suggests that higher $T_c$s may be also achieved, for the same band filling, by increasing the size of the unit cell volume by chemical substitution at the interstitial sites (negative pressure effect).

In conclusion, synchrotron X-ray powder diffraction at elevated pressures has been used to derive the evolution of the structural properties of the high-$T_c$ MgB$_2$ superconductor with pressure. In combination with the pressure dependence of $T_c$, these results provide the detailed dependence of the superconducting properties as both B-B and Mg-B bonding distances decrease and should form a stringent test of competing models for the interpretation of the superconducting pairing mechanism in this material. Detailed band structure calculations should be able to also shed light on the evolution of the charge transfer between Mg and B and decipher the relative importance between the boron layers and the interstitial metal ions to superconductivity.

KP thanks Monbusho for a Visiting Professorship to JAIST. We thank Spring-8 for the provision of syn-
chrotron X-ray beamtime. The work at Aoyama-Gakuin University was partially supported by a Grant-in-Aid for Science Research from the Ministry of Education, Science, Sports and Culture, Japan and by a Grant from CREST. We acknowledge useful discussions with T. Arima, T. Takenobu and S. Suzuki.

TABLE I. Bond distances (Å) for MgB$_2$ at selected pressures.

| Pressure (GPa) | B-B | Mg-B | Mg-Mg |
|---------------|-----|------|-------|
| ambient       | 1.7844(1) | 2.5094(1) | 3.0906(2) |
| 3.23          | 1.7738(1) | 2.4917(1) | 3.0724(1) |
| 6.15          | 1.7694(1) | 2.4837(1) | 3.0646(1) |

FIG. 1. Final observed (open circles) and calculated (solid line) ambient temperature synchrotron X-ray powder diffraction profiles of MgB$_2$ at 1.27 and 5.46 GPa in the range of 7$^\circ$ to 43$^\circ$ ($\lambda = 0.49556$ Å). The lower lines show the difference profiles and the vertical marks indicate the observed reflections.

FIG. 2. Pressure dependence of: (a) the unit cell volume, $V$ and (b) the normalized hexagonal lattice constants ($a/a_0$) and ($c/c_0$) of MgB$_2$ at ambient temperature. The lines through the data points are least-squares fits to the Murnaghan equation-of-state (eq. 1) in (a) and its variants in (b) (see text). Inset. Schematic diagram of the MgB$_2$ structure.

FIG. 3. Superconducting transition temperature, $T_c$ versus unit cell volume, $V$ for MgB$_2$. The $V(P)$ data from Fig. 2(a) were converted to $T_c(V)$ by using the $T_c(P)$ data (solid circles) of ref. [8] to 1.84 GPa. The line through the points is a guide to the eye.
The graph shows the relationship between volume (Å³) and pressure (GPa) for a material. As pressure increases, the volume decreases. The inset figure illustrates the structure of the material at different pressures.
