Homology of weighted path complexes and directed hypergraphs

Yuri Muranov, Anna Szczepkowska, and Vladimir Vershinin

Abstract

We introduce the weighted path homology on the category of weighted directed hypergraphs and describe conditions of homotopy invariance of weighted path homology groups. We give several examples that explain the nontriviality of the introduced notions.

AMS Mathematics Subject Classification 2020: 18G90, 55N35, 05C20, 05C22, 05C25, 05C65, 55U05

Keywords: hypergraph, weighted path complex, category of directed hypergraphs, path homology, digraph, homotopy of directed hypergraphs, weighted path homology

1 Introduction

One of the tools for the investigation of global structures in graph theory are (co)homology theories which were constructed recently by many authors for various categories of (di)graphs, multigraphs, quivers, and hypergraphs [17], [12], [16], [5], [6], [9], [4], and [15].

The notion of directed hypergraphs arises in discrete mathematics as a natural generalization of digraphs and hypergraphs [3] and [8]. At present time there are many mathematical models of various complex systems in which the system is presented by a network whose interacting pairs of nodes are connected by links. Such models are naturally presented by hypergraphs with additional structures [2]. The notions of path, cycle and weight structure on hypergraphs arise naturally for the directed hypergraphs. These concepts allow to investigate global structures on hypergraphs by methods of algebraic topology and, in particular, homology theory. The excellent survey
of application of directed hypergraphs to various aspects of computer sciences is given in paper [1]. The application of homology theory of hypergraphs in the pharmaceutical industries is described, for example, in [7], [14].

In the present paper, we introduce several categories of weighted directed hypergraphs and the notion of homotopy in these categories. Then we define functorial homology theories on such categories using the homology theory of path complexes constructed in [9], [11], and [12]. We describe also the conditions of homotopy invariance of introduced homology groups and we give several examples. In the paper we consider only finite digraphs, path complexes and directed hypergraphs.

2 Path homology of weighted path complexes

A path complex [11] Sec. 3.1 \( \Pi = (V, P) \) consists of a set \( V \) of vertices and a set \( P \) of elementary paths \((i_0 \ldots i_n)\) of vertices such that one-element sequence \((i)\) lies in \( P \) and if \((i_0 \ldots i_n) \in P\) then \((i_1 \ldots i_n) \in P\). The length of a path \((i_0 \ldots i_n)\) is equal to \(n\). We denote by \(\Pi_V = (V, P_V)\) the path complex for which \(P_V\) consists of all paths of finite length on \(V\).

A morphism of path complexes \(f : (V, P) \to (W, Q)\) is given by the pair of maps \((f_V, f_P)\) where \(f_V : V \to W\) and \(f_P(i_0 \ldots i_n) : = (f_V(i_0) \ldots f_V(i_n))\) lays in \(P\). Thus we obtain a category \(\mathcal{P}\) whose objects are path complexes and whose morphisms are morphisms of path complexes.

Let \(J = \{0, 1\}\) be the two-element set. For any set \(V = \{0, \ldots, n\}\), let \(V \times J\) be as usual the Cartesian product. Let \(V'\) be a copy of the set \(V\) with the elements \(\{0', \ldots, n'\}\) where \(i' \in V'\) corresponds to \(i \in V\). Then we can identify \(V \times J\) with \(V \coprod V'\) in such a way that \((i, 0)\) corresponds to \(i\) and \((i, 1)\) corresponds to \(i'\) for all \(i \in V\). Thus \(V\) is identified with \(V \times \{0\} \subset V \times J\) and \(V'\) is identified with \(V \times \{1\} \subset V \times J\). The natural bijection \(V \cong V'\) defines the set of path \(P'\) on the set \(V'\) by the condition: \((i_0' \ldots i_n') \in P'\) iff \((i_0 \ldots i_n) \in P\). We define a path complex \(\Pi' = (V \times J, P')\) where

\[
P' = P \cup P' \cup P^#,
\]

\[
P^# = \{q^# = (i_0 \ldots i_k i'_k i'_{k+1} \ldots i'_n) | q = (i_0 \ldots i_k i_{k+1} \ldots i_n) \in P\}.
\]

There are morphisms \(i_* : \Pi \to \Pi'\) and \(j_* : \Pi \to \Pi'\) which are induced by the natural inclusion of \(V\) in \(V \times \{0\}\) and in \(V \times \{1\}\), respectively.
Definition 2.1. i) A path complex $\Pi = (V, P)$ is called weighted if it is equipped with a function $\delta_V: V \rightarrow R$ where $R$ is a unitary commutative ring. This function is called the weight function. We denote such a path complex by $\Pi^\delta = (V, P, \delta_V)$.

ii) Let $(V, P, \delta_V)$ and $(W, S, \delta_W)$ be weighted path complexes. A morphism $f: (V, P) \rightarrow (W, S)$ of path complexes is a weighted morphism if $\delta_W(f_V(v)) = \delta_V(v)$ for every $v \in V$. We denote such a morphism by $f^\delta$.

Weighted path complexes with weighted morphisms form a category we denote by $\mathcal{P}^\delta$.

Let $\Pi^\delta = (V, P, \delta_V)$ be a weighted path complex. Then the path complex $\Pi^\downarrow$ has the natural structure of the weighted path complex $\Pi^\delta$ with the weighted function $\delta_{V \times J}(v, 0) = \delta_{V \times J}(v, 1) = \delta_V(v)$.

Definition 2.2. i) We call weighted morphisms $f^\delta, g^\delta: \Pi^\delta \rightarrow \Sigma^\delta$ of weighted path complexes weighted one-step homotopic if morphisms $f, g$ are one-step homotopic (see [9, Def. 3.1]) and the homotopy $F: \Pi^\uparrow \rightarrow \Sigma$ is a weighted morphism.

ii) Two weighted morphisms $f^\delta, g^\delta: \Pi^\delta \rightarrow \Sigma^\delta$ of weighted path complexes are homotopic $f^\delta \simeq g^\delta$ if there exists a sequence of weighted morphisms

$$f^\delta = f_0^\delta, f_1^\delta, \ldots, f_n^\delta = g^\delta: \Pi^\delta \rightarrow \Sigma^\delta$$

such that any two consequent morphisms are one-step homotopic.

Thus we obtain homotopy category $h\mathcal{P}^\delta$ whose objects are weighted path complexes and morphisms are classes of weighted homotopic weighted morphisms.

Proposition 2.3. Let $f^\delta, g^\delta: \Pi^\delta \rightarrow \Sigma^\delta$ be weighted morphisms of weighted path complexes which are one-step homotopic as morphisms of path complexes. Then morphisms $f^\delta$ and $g^\delta$ are weighted one-step homotopic.

Proof. It follows from the definition of the weight function $\delta_{V \times J}$. 

Let $\Pi^\delta = (V, P, \delta_V)$. We define the weighted path homology groups $H_*^\delta(\Pi^\delta)$ with coefficients in a unitary commutative ring $R$ similarly to the regular path homology groups [9, Sec. 2]. For $n \geq 0$, let $\mathcal{R}_n^{reg}(V)$ be a module generated by all paths $(i_0 \ldots i_n)$ on the set $V$ which are regular, that is $i_k \neq i_{k+1}$ for $0 \leq k \leq n - 1$ and $\mathcal{R}^{reg}_{-1}(V) = 0$. Let $\mathcal{R}^{reg}_n(P) \subseteq \mathcal{R}^{reg}_n(V)$ be
submodules generated by paths from $P$ for $n \geq 0$ and $R_{-1}^{reg}(P) = 0$. We define a weighted boundary homomorphism

$$\partial_n^w : R_n(V) \to R_{n-1}(V)$$

by putting $\partial_0^w = 0$ and

$$\partial_n^w(e_{i_0 \ldots i_n}) = \sum_{s=0}^{n} (-1)^s \delta_V(i_s)e_{\hat{i}_s \ldots i_n}$$

for $n \geq 1$, where $\hat{i}_s$ means omission of the index $i_s$. Then $(\partial^w)^2 = 0$ \[13, \S3]\.

Let us define $R$-modules $\Omega^w_\ast = \Omega^w_\ast(\Pi^\delta)$ by setting: $\Omega^w_{-1} = 0$ and

$$\Omega^w_n = \{ v \in R_{n-1}^{reg}(P) | \partial^w v \in R_{n-1}^{reg}(P) \}$$

for $n \geq 0$.

Modules $\Omega^w_n$ with the differential induced by $\partial^w$ form a chain complex. Homology groups $H^w_\ast(\Pi^\delta)$ of this complex are called weighted path homology groups.

Recall that a digraph $V = (V_G, E_G)$ is called weighted if it is equipped a weight function $\delta_{V_G} : V \to R$. Let $G^\delta = (V_G, E_G, \delta_{V_G})$ be a weighted digraph without loops. We define a weighted path complex $\mathcal{D}^w(G) = (V_G, P_G, \delta_{V_G})$ in which a path $(i_0 \ldots i_n)$ on the set $V_G$ lies in $P_G$ iff for $k = 1, \ldots, n$ every pair of consequent vertices $i_{k-1}, i_k$ lies in the edge $(i_{k-1} \to i_k) \in E_G$. Thus one gets a functor $\mathcal{D}^w$ from the category of weighted digraphs $\mathcal{D}^\delta$ to the category of weighted path complexes $\mathcal{P}^\delta$. We define the weighted path homology of the weighted digraph by

$$H^w_\ast(G^\delta) := H^w_\ast(\mathcal{D}^w(G^\delta)).$$

Example 2.4. We give two examples of weighted path complexes $\Pi^\delta$ for which the regular homology groups $H_\ast(\Pi)$ and $H^w_\ast(\Pi^\delta)$ with coefficients in $\mathbb{Z}$ are non-isomorphic.

i) Let $\Pi^\delta = (V, P, \delta_V)$ with $V = \{a, b, c, d\}$, $P = \{a, b, c, d, ac, ad, bc, bd\}$ and $\delta_V(a) = \delta_V(b) = 1$, $\delta_V(c) = \delta_V(d) = 0$. The path homology groups of $\Pi = (V, P)$ coincide with the regular path homology groups of the digraph

\[
\begin{array}{ccc}
   c & \searrow & \swarrow \\
   a & \downarrow & b \\
   \swarrow & \searrow & d
\end{array}
\]
We have

\[ H_i(\Pi) = \begin{cases} 
\mathbb{Z} & \text{for } i = 0, 1 \\
0 & \text{for } i \geq 2
\end{cases} \]

and

\[ H^w_i(\Pi^\delta) = \begin{cases} 
\mathbb{Z}^2 & \text{for } i = 0, 1 \\
0 & \text{for } i \geq 2
\end{cases} \]

ii) Let \( \Pi^\delta = (V, P, \delta_V) \) with \( V = \{a, b\} \), \( P = \{a, b\} \), and \( \delta_V(a) = 2, \delta_V(b) = 4 \). The path homology groups of \( \Pi = (V, P) \) coincide with the regular path homology groups of the digraph \( a \to b \). We have

\[ H_i(\Pi) = \begin{cases} 
\mathbb{Z} & \text{for } i = 0 \\
0 & \text{for } i \geq 1
\end{cases} \quad \text{and} \quad H^w_i(\Pi^\delta) = \begin{cases} 
\mathbb{Z} \oplus \mathbb{Z}^2 & \text{for } i = 0 \\
0 & \text{for } i \geq 1
\end{cases} \]

Let us fix a weighted path complex \( \Pi^\delta = (V, P, \delta) \) with a weighted function \( \delta: V \to \mathbb{R} \) such that \( \delta(i) \) is an invertible element for all \( i \in V \). We define a function \( \gamma: V \to \mathbb{R} \) by putting \( \gamma(i) = (\delta(i))^{-1} \). Recall that for the weighted path complex \( \Pi^\delta = (V, P, \delta_V \times J) \), we identify \( V \times \{0\} \) with \( V \), \( V \times \{1\} \) with \( V' \) and, hence, \( \delta_{V \times J}(v, 0) = \delta_{V \times J}(v, 1) = \delta_V(v) = \delta_V(v') \) for \( v \in V \). Thus, for a path \( e_{i_0...i_n} \in R_n^\text{reg}(P) \) and \( 0 \leq k \leq n \), we have \( \delta(i_k) = \delta(i'_k), \gamma(i_k) = \gamma(i'_k) \). For \( n \geq 0 \), we define a homomorphism \( \tau: R_n^\text{reg}(V) \to R_{n+1}^\text{reg}(V \times J) \) on basic regular \( n \)-paths \( v = e_{i_0...i_n} \) by

\[
(2.1) \quad \tau(v) = \sum_{k=0}^{n} \gamma(i_k) (-1)^k e_{i_0...i_k'i'_k...i_n}.
\]

We set \( R_{-1}^\text{reg}(V) = 0 \) and define \( \tau = 0: R_{-1}^\text{reg}(V) \to R_0^\text{reg}(V \times J) \).

**Lemma 2.5.** For \( n \geq 0 \) and any path \( v \in R_n^\text{reg}(V) \), we have

\[
(2.2) \quad \partial^w \tau(v) + \tau(\partial^w v) = v' - v.
\]

**Proof.** It is sufficient to prove the statement for basis elements \( v = e_{i_0...i_n} \).

For \( n = 0 \) and \( v = e_{i_0} \in R_0^\text{reg}(V) \), we have \( \partial^w \tau(e_{i_0}) = \partial^w (\gamma(i_0)e_{i_0'i_0}) = \gamma(i_0) \).
\[
(\delta(i_0)e_{i_0} - \delta(i'_0)e_{i_0}) = \gamma(i_0) \cdot \delta(i_0)[e_{i_0} - e_{i_0}] = e_{i_0} - e_{i_0}, \ \tau(\partial^w v) = \tau(0) = 0,
\]
and so (2.2) is true. Let \( v = e_{i_0 ... i_n} \in R^n_{reg}(V) \) with \( n \geq 1 \). Then

\[
\partial^w (\tau(v)) = \partial^w \left( \sum_{k=0}^{n} (-1)^k \gamma(i_k)e_{i_{0}...i_{k}i'_{k}...i'_{n-1}i'_{n}} \right)
\]

\[
= \sum_{k=0}^{n} (-1)^k \left( \sum_{m=0}^{k} (-1)^m \delta(i_m) \gamma(i_k)e_{i_{0}...i_{k}i'_{k}...i'_{n}} \right)
\]

\[
+ \sum_{k=0}^{n} (-1)^k \left( \sum_{m=k}^{n} (-1)^{m+1} \delta(i'_m) \gamma(i_k)e_{i_{0}...i_{k}i'_{k}...i'_{n}} \right)
\]

\[
= \sum_{0 \leq m \leq k \leq n} (-1)^{k+m} \delta(i_m) \gamma(i_k)e_{i_{0}...i_{k}i'_{k}...i'_{n}}
\]

\[
+ \sum_{0 \leq k \leq m \leq n} (-1)^{k+m+1} \delta(i'_m) \gamma(i_k)e_{i_{0}...i_{k}i'_{k}...i'_{n}}
\]

and

\[
\tau(\partial^w v) = \tau \left( \sum_{m=0}^{n} (-1)^m \delta(i_m)e_{i_{0}...i_{m}...i_{n}} \right)
\]

\[
= \sum_{m=0}^{n} (-1)^m \left( \sum_{k=0}^{m-1} (-1)^k \delta(i'_m) \gamma(i_k)e_{i_{0}...i_{k}i'_{k}...i'_{n}} \right)
\]

\[
+ \sum_{m=0}^{n} (-1)^m \left( \sum_{k=m+1}^{n} (-1)^{k-1} \delta(i_m) \gamma(i_k)e_{i_{0}...i_{k}i'_{k}...i'_{n}} \right)
\]

\[
= \sum_{0 \leq k \leq m \leq n} (-1)^{k+m} \delta(i'_m) \gamma(i_k)e_{i_{0}...i_{k}i'_{k}...i'_{n}}
\]

\[
+ \sum_{0 \leq m \leq k \leq n} (-1)^{k+m-1} \delta(i_m) \gamma(i_k)e_{i_{0}...i_{k}i'_{k}...i'_{n}}
\]

Hence

\[
\partial^w \tau(v) + \tau(\partial^w v) = \sum_{0 \leq k \leq n} (-1)^{k+k} \delta(i_k) \gamma(i_k) e_{i_0 \cdots i_k i'_{k+1} \cdots i'_n} \\
+ \sum_{0 \leq k \leq n} (-1)^{k+k+1} \delta(i_k) \gamma(i_k) e_{i_0 \cdots i_k i'_{k+1} \cdots i'_n} \\
= \sum_{0 \leq k \leq n} e_{i_0 \cdots i_k i'_{k+1} \cdots i'_n} - \sum_{0 \leq k \leq n} e_{i_0 \cdots i_k i'_{k+1} \cdots i'_n} \\
= e_{i_0 \cdots i'_n} - e_{i_0 \cdots i'_{n-1}} \\
+ \left( \sum_{0 \leq k \leq n-1} e_{i_0 \cdots i_k i'_{k+1} \cdots i'_n} - \sum_{0 \leq k \leq n-1} e_{i_0 \cdots i_k i'_{k+1} \cdots i'_n} \right) \\
= e_{i_0 \cdots i'_n} - e_{i_0 \cdots i'_{n-1}} = v' - v.
\]

\[
\text{Theorem 2.6.} \text{ Let } f^\delta \simeq g^\delta : \Pi^\delta = (V, P, \delta_V) \to (W, S, \delta_W) = \Sigma^\delta \text{ be weighted homotopic morphisms of weighted path complexes such that the elements } \delta_V(i) \in R \text{ are invertible for all } i \in V. \text{ Then morphisms } f^\delta \text{ and } g^\delta \text{ induce the chain homotopic morphisms of weighted chain complexes } \\
f^\delta_* \simeq g^\delta_* : \Omega^w_*(P) \to \Omega^w_*(S) \\
\text{and hence, the equal homomorphisms of weighted path homology groups.}
\]

\text{Proof.} \text{ It is sufficient to consider the case of one-step weighted homotopy } F : \Pi^{\delta} \to \Sigma^{\delta} \text{ between } f^{\delta} \text{ and } g^{\delta}. \text{ By definition } F_* \circ [i_*]_* = f_* \text{ and } F_* \circ [j_*]_* = g_* . \text{ We define a chain homotopy } L_n : \Omega^w_n(P) \to \Omega^w_{n+1}(S) \text{ such that } \\
\partial^w L_n + L_{n-1} \partial^w = g_* - f_* . \\
\text{Let the element } v \in R^\text{reg}_n(P) \text{ belong to } \Omega^w_n(P). \text{ Then, by definition, } \tau(v) \in R^\text{reg}_{n+1}(P^\dagger). \text{ To prove that } \tau(v) \in \Omega^w_{n+1}(P^\dagger), \text{ it is sufficient to check that } \\
\partial^w \tau(v) \in R^\text{reg}(P^\dagger). \text{ By definition, } \partial^w v \in R^\text{reg}_{n-1}(P) \subset \Omega^w_{n-1}(V). \text{ By Lemma}
\[ \partial^w \tau(v) = -\tau(\partial^w v) + v' - v \] where the right summands belongs to \( \mathcal{R}^{\text{reg}}(P^\uparrow) \). Hence, \( \tau(v) \in \Omega^w_{n+1}(P^\uparrow) \). For \( n \geq 0 \), we define homomorphisms

\[ L_n(v) : \Omega^w_n(P) \to \Omega^w_{n+1}(S) \]

by \( L_n(v) := F_*(\tau(v)) \). Now, we check that \( L_n \) is a chain homotopy:

\[
(\partial^w L_n + L_{n-1} \partial^w)(v) = \partial^w (F_*(\tau(v))) + F_*(\partial^w v) \\
= F_*(\partial^w \tau(v)) + F_*(\partial^w v) \\
= F_*(\partial^w \tau(v) + \tau(\partial^w v)) \\
= F_*(v' - v) = g^\delta_*(v) - f^\delta_*(v).
\]

\[ \square \]

3 Path homology of weighted directed hypergraphs

**Definition 3.1.** i) A directed hypergraph \( G = (V, E) \) consists of a finite set of vertices \( V \) and a set of arrows \( E = \{e_1, \ldots, e_n\} \) where \( e_i \in E \) is an ordered pair \((A_i, B_i)\) of disjoint non-empty subsets of \( V \) such that \( V = \bigcup_{e_i \in E} (A_i \cup B_i) \). The set \( A = \text{orig}(A \to B) \) is called the origin of the arrow and the set \( B = \text{end}(A \to B) \) is called the end of the arrow. The elements of \( A \) are called the initial vertices of \( A \to B \) and the elements of \( B \) are called its terminal vertices.

ii) A directed hypergraph \( G = (V, E) \) is called weighted if it is equipped with a function \( \delta_V : V \to R \) where \( R \) is a unitary commutative ring. This function is called the weight function. We denote such a directed hypergraph by \( G^\delta = (V, E, \delta_V) \).

For a set \( X \) let \( \mathcal{P}(X) \), denote as usual its power set. We define a set \( \mathcal{P}(X) : = \{\mathcal{P}(X) \setminus \emptyset\} \times \{\mathcal{P}(X) \setminus \emptyset\} \). Every map \( f : V \to W \) induces a map \( \mathcal{P}(f) : \mathcal{P}(V) \to \mathcal{P}(W) \). For a directed hypergraph \( G = (V, E) \), by Definition 3.1 we have the natural map \( \varphi_G : E \to \mathcal{P}(V) \) defined by \( \varphi_G(A \to B) : = (A, B) \). Let \( X \subset V \) be a subset of the set of vertices of a weighted directed hypergraph \( G^\delta \). Define the weight \( |X| \) of a set \( X \) by setting

\[ |X| : = \sum_{x \in X} \delta_V(x). \]
Let $G = (V_G, E_G)$ and $H = (V_H, E_H)$ be two directed hypergraphs. By [15 Def. 2.1], the morphism $f: G \rightarrow H$ is given by a pair of maps $f_V: V_G \rightarrow V_H$ and $f_E: E_G \rightarrow E_H$ such that the following diagram

$$
\frac{E_G}{f_E} \xrightarrow{\phi_G} \mathbb{P}(V_G) \quad \frac{\downarrow f_E}{\downarrow \mathbb{P}(f_V)} \quad \frac{E_H}{f_E} \xrightarrow{\phi_H} \mathbb{P}(V_H)
$$

is commutative. Let $G^\delta = (V_G, E_G, \delta_{V_G})$ and $H^\delta = (V_H, E_H, \delta_{V_H})$ be two weighted directed hypergraphs and let $f: G \rightarrow H$ be a morphism.

**Definition 3.2.**

i) The morphism $f$ is called *vertex-weighted* if $\delta_{V_H}(f_V(v)) = \delta_{V_G}(v)$ for every $v \in V_G$. We denote such morphism by $f^v$.

ii) The morphism $f$ is called *edge-weighted* if for every $(A \rightarrow B) \in E_G$ and $f_E(A \rightarrow B) = A' \rightarrow B'$ the conditions $|A| = |A'|$, $|B| = |B'|$ are satisfied.

iii) The morphism $f$ is called *strong-weighted* if it is *vertex-weighted* and *edge-weighted* simultaneously. We denote such a morphism by $f^s$.

Thus, we obtain categories $\mathcal{DH}^v$, $\mathcal{DH}^e$, and $\mathcal{DH}^s$ of vertex-weighted, edge-weighted, and strong-weighted directed hypergraphs, respectively.

Let $G = (V_G, E_G)$ be a directed hypergraph. We define subsets $P_0(G)$, $P_1(G)$, and $P_{01} = P_0(G) \cup P_1(G)$ of $\mathbb{P}(V_G) \setminus \emptyset$ by setting

$$
P_0(G) = \{A \in \mathbb{P}(V_G) \setminus \emptyset | \exists B \in \mathbb{P}(V_G) \setminus \emptyset : A \rightarrow B \in E_G\},$$

$$P_1(G) = \{B \in \mathbb{P}(V_G) \setminus \emptyset | \exists A \in \mathbb{P}(V_G) \setminus \emptyset : A \rightarrow B \in E_G\}.$$

We define a digraph $\mathfrak{R}(G) = (V^n_G, E^n_G)$ where $V^n_G = \{C \in \mathbb{P}(V) \setminus \emptyset | C \in P_0(G)\}$ and $E^n_G = \{A \rightarrow B | (A \rightarrow B) \in E\}$. Note that $\mathfrak{R}$ is a functor from the category $\mathcal{DH}$ of directed hypergraphs [15] to the category $\mathcal{D}$ of digraphs.

We equip the digraph $\mathfrak{R}(G)$ with a structure of a *weighted digraph* by defining a weight function in the following way $\delta_{V^n_G}(A) \coloneqq |A|$ where $|A|$ is the weight of the set $A$. We denote such a weighted digraph by $\mathfrak{R}^w(G)$.

**Proposition 3.3.** Every edge-weighted morphism of weighted directed hypergraphs $f^e: G^\delta \rightarrow H^\delta$ defines a morphism of weighted digraphs

$$[\mathfrak{R}^w(f)] = (f^n_V, f^n_E): (V^n_G, E^n_G, \delta_{V^n_G}) \rightarrow (V^n_H, E^n_H, \delta_{V^n_H})$$

by $f^n_V(C) = [\mathbb{P}(f)] \circ \phi_G(C)$ and $f^n_E(A \rightarrow B) = (f_V(A) \rightarrow f_V(B)) \in E^n_H$. Thus, we obtain a functor $\mathfrak{R}^w$ from the category $\mathcal{DH}^e$ of edge-weighted directed hypergraphs to the category $\mathcal{D}^\delta$ of weighted digraphs.
The composition $\mathcal{D}^w \circ \mathcal{W}^w$ is a functor $\mathcal{D}\mathcal{H}^e \to \mathcal{P}^\delta$, and we define the edge-weighted path homology groups of the weighted directed hypergraph $G^\delta$ by

$$H^e_*(G) := H^*_{\delta}(\mathcal{D}^w \circ \mathcal{W}^w(G)).$$

Now we use the notion of a line digraph $I_n = (V_{I_n}, E_{I_n})$ ($n \geq 0$) from [10] Sec. 3.1. Note that we have two digraphs $I_1$, namely $0 \to 1$ and $1 \to 0$. For a digraph $G$ the box product $G \square I_n$ is a digraph with $V_{G\square I_n} = V_G \times V_{I_n}$ and with the set of arrows $E_{G\square I_n}$ such that there is an arrow $((x, i) \to (y, j)) \in E_{G\square I_n}$ if and only if either $x = y$ and $i \to j$ or $x \to y$ and $i = j$, see [10]. If $G^\delta$ is a weighted directed hypergraph, we equip the digraph $G \square I_n$ with the structure of a weighted digraph by setting $\delta_{V_{G\square I_n}}(v, i) = \delta_G(v)$ for $v \in V_G$, $i \in V_{I_n}$. We denote this weighted digraph by $G^\delta \square I_n$.

For a directed hypergraph $G$, the box product $G \square I_n = (V_{G\square I_n}, E_{G\square I_n})$ is a directed hypergraph with $V_{G\square I_n} = V_G \times V_{I_n}$ and the set of arrows $E_{G\square I_n}$ being a union of $\{A \times i \to B \times i\}$, $(A \to B) \in E_G$, $i \in V_{I_n}$ and $\{A \times i \to A \times j\}$, $(i \to j) \in E_{I_n}$, $A \in \mathcal{P}_{01}(G)$. If $G^\delta$ is a weighted directed hypergraph, we equip the directed hypergraph $G \square I_n$ with the structure of a weighted directed hypergraph by setting $\delta_{V_{G\square I_n}}(v \times i) = \delta_{V_G}(v)$ for $v \in V_G$, $i \in V_{I_n}$. We denote this weighted directed hypergraph by $G^\delta \square I_n$. Recall, see e.g. [15], that two morphisms $f_0, f_1 : G \to H$ of directed hypergraphs are called one-step homotopic $f_0 \simeq_1 f_1$, if there exists a morphism $F : G \square I_1 \to H$, such that

$$F|_{G \square \{0\}} = f_0 : G \square \{0\} \to H, \quad F|_{G \square \{1\}} = f_1 : G \square \{1\} \to H.$$ 

Two morphisms $f, g : G \to H$ of directed hypergraphs are called homotopic $f \simeq g$, if there exists a sequence of morphisms $f_i : G \to H$ for $i = 0, \ldots, n$ such that $f = f_0 \simeq_1 f_1 \simeq_1 \cdots \simeq_1 f_n = g$.

**Proposition 3.4.** Let $f_0^\chi, f_1^\chi : G^\delta \to H^\delta$ be weighted morphisms of weighted directed hypergraphs where $\chi$ is $v$, $e$, or $s$. If $f_0$ and $f_1$ are one-step homotopic as morphisms of directed hypergraphs by means of a homotopy $F$, then $F$ can be considered as a weighted morphism $F^\chi : G^\delta \times I_1 \to H^\delta$.

**Proof.** It follows from the definition of $G^\delta \square I_1$. 

If $\chi$ means one of the values $v$, $e$, or $s$ we obtain a homotopy category of $\chi$-weighted directed hypergraphs $h\mathcal{D}\mathcal{H}^\chi$ whose objects are weighted directed hypergraphs and morphisms are classes of homotopic $\chi$-weighted morphisms.
Lemma 3.5. Let $I_1 = (0 \to 1)$ and $G^\delta$ be a weighted digraph. Then there is an equality $[\mathcal{D}^w(G^\delta)]^{\uparrow \delta} = \mathcal{D}^w(G^\delta \Box I_1)$ of weighted path complexes.

Proof. It follows from the definitions of the functor $\mathcal{D}^w$, the box product, and the path complex $\Pi^\uparrow$.

Lemma 3.6. Let $G^\delta$ be a weighted directed hypergraph and $I_1 = (0 \to 1)$. Then there is an equality $[\mathcal{D}^w(\mathcal{M}^w(G))]^{\uparrow \delta} = \mathcal{D}^w(\mathcal{M}^w(G \Box I_1))$ of the weighted path complexes.

Proof. By Lemma 3.5, $[\mathcal{D}^w(\mathcal{M}^w(G))]^{\uparrow \delta} = \mathcal{D}^w(\mathcal{M}^w(G \Box I_1))$. The weighted digraphs $\mathcal{M}^w(G \Box I_1)$ and $\mathcal{M}^w(G \Box I_1)$ are equal by definition of the box product and the functor $\mathcal{M}^w$. Hence $\mathcal{D}^w(\mathcal{M}^w(G \Box I_1)) = \mathcal{D}^w(\mathcal{M}^w(G \Box I_1))$ and the result follows.

Theorem 3.7. Let $f^e, g^e : G^\delta \to H^\delta$ be edge-weighted homotopic morphisms of weighted directed hypergraphs and assume that all elements of the set $K = \{ k \in \mathbb{R} | k = |A|, A \in \mathbb{P}_{01}(G) \}$ are invertible in $\mathbb{R}$. Then the induced homomorphisms $f_* : H^e_*(G, R) \to H^e_*(H, R)$ coincide.

Proof. It follows from Lemma 3.6 and Theorem 2.6.

Let us consider a subcategory $h\mathcal{DH}^1$ of the category $h\mathcal{DH}$ in which $\delta_V \equiv 1$ for every weighted directed hypergraph.

Theorem 3.8. If the ring $R$ is an algebra over rationals, then the weighted homology groups $H^e_*(-, R)$ are homotopy invariant on the category $h\mathcal{DH}^1$.

Proof. Similar to the proof of Theorem 3.7.

Now, we describe several weighted path homology theories on the category $\mathcal{DH}$ which are similar to the path homology theories on $\mathcal{D}H$ constructed in [15, Sec. 3]. We present here only functorial and homotopy invariant theories. The other path homology theories from [15] can be transferred to the case of weighted hypergraphs similarly. Let us consider the functors $\mathfrak{C}$, $\mathfrak{B}$, and the functor given by the composition $\mathfrak{Y} \circ \mathfrak{C}$ from the category $\mathcal{D}H$ to the category $\mathcal{P}$ of path complexes [15]. We recall the definition of these functors for objects, then it will be clear for morphisms.
Let \( G = (V, E) \) be a directed hypergraph. Define a path complex \( \mathcal{C}(G) = (V^c, P_G^c) \) by
\[
V^c = V \quad \text{and a path } (i_0 \ldots i_n) \in P_V \text{ lies in } P_G^c \text{ iff for any pair of consequent vertices } (i_k, i_{k+1}) \text{ either } i_k = i_{k+1} \text{ or there is an edge } e = (A \to B) \in E \text{ such that } i_k \text{ is the initial vertex and } i_{k+1} \text{ is the terminal vertex of } e.
\]

Recall the definition of the \textit{concatenation} \( p \lor q \) of two paths \( p = (i_0, \ldots, i_n) \) and \( q = (j_0, \ldots, j_m) \) on a set \( V \). The concatenation is well defined only for \( i_n = j_0 \) and in such a case, it is a path on \( V \) given by \( p \lor q = (i_0 \ldots i_n j_1 \ldots j_m) \).

Define a path complex \( \mathcal{B}(G) = (V^b, P_G^b) \) where \( V^b_G = V \) and a path \( q = (i_0 \ldots i_n) \in P_V \text{ lies in } P_G^b \text{ iff there is a sequence of edges } (A_0 \to B_0), \ldots, (A_r \to B_r) \text{ in } E \text{ such that } B_i \cap A_{i+1} \neq \emptyset \text{ for } 0 \leq i \leq r - 1 \text{ and the path } q \text{ can be presented in the form}
\[
(p_0 \lor v_0 w_0 \lor p_1 \lor v_1 w_1 \lor p_2 \lor \cdots \lor p_r \lor v_r w_r \lor p_{r+1})
\]
where \( p_0 \in P_{A_0}, p_{r+1} \in P_{B_r}, v_i \in A_i, w_i \in B_i, p_i \in P_{B_{i-1}} \cap P_{A_i} \) for \( 1 \leq i \leq r \) and all concatenations are well defined.

Recall that a \textit{hypergraph} \( G = (V, E) \) consists of a non-empty set \( V \) of vertices and a set of edges \( E = \{e_1, \ldots, e_n\} \) which are distinct subsets of \( V \) such that \( \bigcup_{i=1}^n e_i = V \) and every \( e_i \) contains strictly more than one element.

For a directed hypergraph \( G \), we define a hypergraph \( \mathcal{E}(G) = (V^e, E^e) \) where
\[
E^e = \{C \in \mathcal{P}(V) \setminus \emptyset \mid C = A \cup B, (A \to B) \in E\}.
\]

For a hypergraph \( G = (V, E) \), define a path complex \( \tilde{\mathcal{H}}^2(G) = (V^2, P_G^2) \) of \textit{density two} where \( V^2 = V \) and a path \( (i_0 \ldots i_n) \in P_V \text{ lies in } P_G^2 \text{ iff every two consequent vertices of this path lie in an edge } e \in E, \text{ see } [20]. \text{ Thus for every directed hypergraph } G \text{ the composition } \tilde{\mathcal{H}}^2 \circ \mathcal{E} \text{ defines a path complex } \tilde{\mathcal{H}}^2 \circ \mathcal{E}(G).

For a weighted directed hypergraph \( G^\delta = (V, E, \delta_V) \), the path complexes \( \mathcal{C}(G), \mathcal{B}(G), \) and \( \tilde{\mathcal{H}}^2 \circ \mathcal{E}(G) \) have the natural structure of weighted path complexes given by the weight function \( \delta_V : V \to \mathbb{R} \). We denote weighted path complexes by \( \mathcal{C}^w(G^\delta), \mathcal{B}^w(G^\delta), \) and \( [\tilde{\mathcal{H}}^2 \mathcal{E}(G^\delta)]^w \), respectively.

**Proposition 3.9.** If \( f^\circ : G^\delta \to H^\delta \) is a vertex-weighted morphism of weighted directed hypergraphs, then the morphisms
\[
\mathcal{C}(f): \mathcal{C}(G) \to \mathcal{C}(H),
\mathcal{B}(f): \mathcal{B}(G) \to \mathcal{B}(H),
\tilde{\mathcal{H}}^2 \mathcal{E}(f): \tilde{\mathcal{H}}^2 \mathcal{E}(G) \to \tilde{\mathcal{H}}^2 \mathcal{E}(H)
\]
are vertex weighted for the weighted function $\delta_V$. Thus, we have the functors $C^v$, $B^v$, and $[\tilde{H}_2^\cdot]^v$ from $\mathcal{DH}^v$ to $\mathcal{P}^\delta$.

**Proof.** It follows from the definition of morphisms in the category $\mathcal{DH}^v$ and from the definition of the weight function on the objects of corresponding categories. \qed

For any weighted directed hypergraph $G^\delta = (V, E, \delta_V)$, we call

$$
\begin{align*}
H^c_v(G^\delta) &:= H^w_v(C^v(G^\delta)), \\
H^b_v(G^\delta) &:= H^w_v(B^v(G^\delta)), \\
H^2_v(G^\delta) &:= H^w_v([\tilde{H}_2^\cdot]^v(G^\delta)),
\end{align*}
$$

as weighted path homology groups, weighted bold path homology groups, and weighted non-directed path homology groups of density two, respectively.

Now we reformulate Lemma 3.5, Lemma 3.10, and Lemma 3.16 of [15] for the case of functors $C^v$, $B^v$, and $[\tilde{H}_2^\cdot]^v$ from $\mathcal{DH}^v$ to $\mathcal{P}^\delta$. Let $G^\delta = (V, E, \delta_V)$ be a weighted directed hypergraph and $I_1 = (0 \to 1)$.

**Lemma 3.10.** i) There is a natural isomorphism $C^v(G^\delta \Box I_1) \cong [[C^v(G^\delta)]^\uparrow]^\delta$ of weighted path complexes.

ii) There exists an inclusion $\lambda^v: [[B^v(G^\delta)]^\uparrow]^\delta \to B^v(G^\delta \Box I_1)$ of weighted path complexes. The restrictions of $\lambda^v$ to the images of the morphisms $i_\cdot$ and $j_\cdot$, defined in Section 2, are the natural identifications.

iii) There is the inclusion $\mu^v: [[\tilde{H}_2^\cdot \circ E]^v(G^\delta)]^\uparrow]^\delta \to [\tilde{H}_2^\cdot \circ E]^v(G^\delta \Box I_1)$ of weighted path complexes.

**Proof.** By the definition, the weight functions on the vertex set $V \times J$ are given by the function $\delta_{V \times J}(v, 0) = \delta_{V \times J}(v, 1) = \delta_V(v)$ and hence, coincide for all path complexes above. Now the result follows from [15]. \qed

Let $H^\chi_v(G^\delta)$ denote one of the homology groups $H^c_v(G^\delta)$, $H^b_v(G^\delta)$, $H^2_v(G^\delta)$ defined in (3.2).

**Theorem 3.11.** Let $f^v, g^v: G^\delta_1 = (V_1, E_1, \delta_{V_1}) \to G^\delta_2 = (V_2, E_2, \delta_{V_2})$ be vertex-weighted homotopic morphisms of weighted directed hypergraphs and assume that all elements of the set $K = \{k \in R|k = \delta_{V_1}(v), v \in V_1\}$ are invertible in $R$. Then the induced homomorphisms

$$f^v_\ast, g^v_\ast: H^\chi_v(G^\delta_1, R) \to H^\chi_v(G^\delta_2, R)$$

coincide.
Proof. It follows from Lemma 3.10 and Theorem 2.6.
