ABSTRACT: The charges of the twisted D-branes for the two exceptional cases (SO(8) with the triality automorphism and $E_6$ with charge conjugation) are determined. To this end the corresponding NIM-reps are expressed in terms of the fusion rules of the invariant subalgebras. As expected the charge groups are found to agree with those characterising the untwisted branes.

KEYWORDS: D-branes, Conformal Field Models in String Theory.
1. Introduction

A lot of information about the dynamics of D-branes is encoded in their charges. In particular, the D-brane charges constrain possible decay processes, and thus play an important role in stability considerations. There is evidence that these charges take values in (twisted) K-theory \([1, 2, 3]\). For D-branes on a simply connected group manifold \(G\), the charge group is conjectured to be the twisted K-theory \(k + h^\vee K(G)\) \([4, 5]\), where the twist involves an element of the third cohomology group \(H^3(G, \mathbb{Z})\), the Wess-Zumino form of the underlying Wess-Zumino-Witten (WZW) model at level \(k\).

For all simple, simply connected Lie groups \(G\), the twisted K-theory has been computed in \([6]\) (see also \([7, 8]\)) to be

\[
K(G) = \bigoplus_{i=0}^{2\text{rk}(G)-1} \mathbb{Z} \oplus \cdots \oplus \mathbb{Z} \oplus M(G,k) ,
\]

where \(M(G,k)\) is the integer

\[
M(G,k) = \frac{k + h^\vee}{\text{gcd}(k + h^\vee, L)} .
\]

Here \(h^\vee\) is the dual Coxeter number of the finite dimensional Lie algebra \(\hat{g}\), and \(L\) only depends on \(G\) (but not on \(k\)). In fact, except for the case of \(C_n\) that will not concern us in this paper, \(L\) is

\[
L = \text{lcm}\{1, 2, \ldots, h - 1\} ,
\]

where \(h\) is the Coxeter number of \(\hat{g}\). For \(\hat{g} = A_n\) this formula was derived in \([9]\) (see also \([10]\)), while the formulae in the other cases were checked numerically up to very high levels in \([11]\). For the classical Lie algebras and \(G_2\) an alternative expression for \(M\) was also derived in \([8]\).
These results should be compared with the charges that can be determined directly in terms of the underlying conformal field theory. The idea behind this approach is that brane configurations that are connected by RG flows should carry the same charge. These constraints were used in [12] to determine the charge group of \( su(2) \). The constraint equations were generalised in [9] to the branes \( a \in \mathcal{B}^\omega_k \) of an arbitrary WZW model that preserve the full affine symmetry algebra \( \mathfrak{g} \) up to some automorphism \( \omega \). There it was argued that the charges \( q_a \) satisfy

\[
\dim(\lambda) \ q_a = \sum_{b \in \mathcal{B}^\omega_k} N^{\lambda a}_{\lambda b} q_b , \tag{1.4}
\]

where \( \lambda \in \mathcal{P}_k^+(\bar{\mathfrak{g}}) \) is a dominant highest-weight representation of the affine Lie algebra \( \mathfrak{g} \) at level \( k \), \( \dim(\lambda) \) is the Weyl-dimension of the corresponding representation of the horizontal subalgebra \( \bar{\mathfrak{g}} \), and \( N^{\lambda a}_{\lambda b} \) are the NIM-rep coefficients appearing in the Cardy analysis. In this paper we shall ignore the low level \((k = 1, 2)\) subtleties discussed in [11] and assume that \( k \) is sufficiently big \((k \geq 3)\).

For the trivial automorphism \((\omega = \text{id})\), the branes can be labelled by dominant highest weights of \( \mathfrak{g} \), \( \mathcal{B}^{\text{id}}_k \cong \mathcal{P}_k^+(\bar{\mathfrak{g}}) \). In this case, the constraints (1.4) were evaluated in [11]. The charges are given (up to rescalings) by the Weyl-dimensions of the corresponding representations, \( q_\lambda = \dim(\lambda) \), and the charge is conserved only modulo \( \mathcal{M}(G,k) \). Thus, the untwisted branes account for one summand \( \mathbb{Z}_{\mathcal{M}(G,k)} \) of the K-group (1.1).

For nontrivial outer automorphisms, a similar analysis was carried through in [13]. Here, the D-branes are parametrised by \( \omega \)-twisted highest weight representations \( a \) of \( \mathfrak{g}_k \) [14, 15, 16], and the NIM-rep coefficients are given by twisted fusion rules [16]. The twisted representations can be identified with representations of the invariant subalgebra \( \bar{\mathfrak{g}}^{\omega} \) consisting of \( \omega \)-invariant elements of \( \bar{\mathfrak{g}} \), and we can view \( \mathcal{B}^\omega_k \) as a subset of \( \mathcal{P}^+_k(\bar{\mathfrak{g}}^{\omega}) \), where \( k' = k + h^{\vee}(\bar{\mathfrak{g}}) - h^{\vee}(\bar{\mathfrak{g}}^{\omega}) \). It was found that the charge \( q_a \) of \( a \in \mathcal{B}^\omega_k \) is again (up to rescalings) given by the Weyl dimension\(^1\) of the representation of \( \bar{\mathfrak{g}}^{\omega} \), \( q_a = \dim(a) \), and that the charge identities are only satisfied modulo \( \mathcal{M}(G,k) \). Thus each such class of twisted D-branes accounts for another summand \( \mathbb{Z}_{\mathcal{M}(G,k)} \) of the charge group. Since the number of automorphisms does not grow with the level, these constructions do not in general account for all the charges of (1.1); for the case of the \( A_n \) series, a proposal for the D-branes that may carry the remaining charges was made in [17, 18] (see also [19]).

The analysis of [13] was only done for all order-2 automorphisms of the classical Lie groups. There exist two ‘exceptional’ automorphisms, namely the order-3 automorphism of \( D_4 \) (triality), and the order-2 automorphism of \( E_6 \) (charge conjugation). These two cases are the subject of this paper. We will find again that with the charge assignment \( q_a = \dim(a) \), the charge identities are satisfied modulo \( \mathcal{M}(G,k) \). Thus each such class of D-branes accounts for another summand of the charge group.\(^2\)

\(^1\)A similar proposal was made in [21] based on an analysis for large level.

\(^2\)For the case of \( D_4 \), there are in total five ‘twisted’ classes of branes that are associated to \( \omega, \omega^2, C, \omega C \) and \( \omega^2 C \), where \( C \) denotes charge conjugation. The corresponding NIM-reps are all closely related to the one discussed in this paper, or the charge conjugation NIM-rep discussed in [13] (see [16]). The arguments given here, together with the results of [13] therefore imply that these five twisted classes of D-branes account for five summands in (1.1).
The plan of the paper is as follows. In the remainder of this section we shall explain the main steps in proving these results that are common to both cases. The details of the analysis for the case of the triality automorphism of $D_4$ (whose invariant subalgebra is $G_2$) is given in section 2. The corresponding analysis for the charge conjugation automorphism of $E_6$ (whose invariant subalgebra is $F_4$) is given in section 3.

1.1 Some notation and a sketch of the proof

We begin by briefly introducing some notation. The $\omega$-twisted D-branes are characterised by the gluing conditions

\[
(J_a^\alpha + \omega(J_{\bar{a}}^\alpha)) \langle \alpha \rangle = 0,
\]

where $J_a^\alpha$ are the generators of $g$. Every boundary state can be written in terms of the $\omega$-twisted Ishibashi states

\[
\langle \alpha \rangle = \sum_{\mu \in \mathcal{E}_k^\omega} \psi_{\alpha \mu} \langle \mu \rangle^\omega,
\]

where $\langle \mu \rangle^\omega$ is the (up to normalisation) unique state satisfying (1.3) in the sector $\mathcal{H}_\mu \otimes \mathcal{H}_{\bar{\mu}}^\ast$. The sum in (1.4) runs over the so-called exponents that consist of the weights $\mu \in \mathcal{P}_k^+(\bar{g})$ that are invariant under $\omega$. The NIM-rep coefficients are determined by the Verlinde-like formula

\[
\mathcal{N}_{\lambda a}^b = \sum_{\mu \in \mathcal{E}_k^\omega} \psi_{\alpha \mu}^a S_{\lambda \mu} \psi_{\alpha \mu} \frac{S_{\rho \mu}}{S_{\rho \mu}};
\]

they define a non-negative integer matrix representation (NIM-rep) of the fusion rule algebra. (For a brief review of these matters see for example [13] and [20].)

It is clear on general grounds (see [13]) that for any charge assignment $q_a$ for $a \in \mathcal{B}_k^\omega$, the charge identity (1.4) can at most be satisfied modulo $M(G,k)$. Our strategy will therefore be to construct a solution that solves (1.4) modulo $M(G,k)$. This solution is again given by $q_a = \dim(a)$. Furthermore, we can show that this solution of the charge equation is unique (up to trivial rescalings).

Our arguments will depend on the particularities of the two cases, but the general strategy is the same. The key observation of our analysis in both cases is a relation of the form

\[
\mathcal{N}_{\lambda a}^b = \sum_{\gamma, i} \varphi_{\lambda \gamma}^i \varepsilon_i N_{\gamma a} \rho_i(b)
\]

that expresses the NIM-rep coefficients $\mathcal{N}_{\lambda a}^b$ in terms of the fusion rules $N_{\gamma a} \rho_i(b)$ of the affine algebra corresponding to $\bar{g}^\omega$. Here $\varphi_{\lambda \gamma}^i$ is the branching coefficient which denotes how often the representation $\gamma$ of $\bar{g}^\omega$ appears in the restriction of the representation $\lambda$ to $\bar{g}$. The $\rho_i$ are maps $\rho_i : \mathcal{B}_k^\omega \rightarrow \mathcal{P}_k^+(\bar{g}^\omega)$ and $\varepsilon_i$ is a sign attributed to the map $\rho_i$. Furthermore $k'$ is defined as before, $k' = k + h^\omega(\bar{g}) - h^\omega(\bar{g}^\omega)$. In the cases studied in [13] analogous formulae for the NIM-rep coefficients were used for which the $\rho_i$ could be expressed in terms of simple currents. In the current context where the invariant algebras are $G_2$ and $F_4$, such simple currents do not exist. Nevertheless it is possible to find such maps $\rho_i$ (see (2.13) and (3.8) below for the specific formulae) that 'mimic' the action of the simple currents.
The different maps \( \rho_i \) have disjoint images, and we can write
\[
\mathcal{P}^+(\mathfrak{g}^\omega) = \bigcup_i \rho_i (\mathcal{B}_k^\omega) \cup \mathcal{R}_k ,
\]
where \( \mathcal{R}_k \) denotes the remainder. The second key ingredient in our proof are the relations
\[
\dim(\rho_i(a)) = \varepsilon_i \dim(a) \quad a \in \mathcal{B}_k^\omega \quad (1.10)
\]
\[
\dim(b) = 0 \quad b \in \mathcal{R}_k .
\]
Both of these identities hold modulo \( M(G, k') \). Finally we observe by explicit inspection of the above formulae for \( M(G, k) \) that in the two cases of interest
\[
M(G, k) = M(G^\omega, k') .
\]
This then allows us to reduce the proof of the charge identities for the twisted D-branes of \( G \) to that of the untwisted D-branes of \( G^\omega \). In fact, the argument is simply
\[
\sum_{b \in \mathcal{B}_k^\omega} N_{\lambda a}^b \dim_{G^\omega}(b) = \sum_{b \in \mathcal{B}_k^\omega} \sum_i \sum_{\gamma} \varepsilon_i \varphi_\gamma^\omega N_{\gamma a}^i \dim_{G^\omega}(b) \mod M(G, k)
\]
\[
= \sum_{\gamma} \varphi_\gamma^\omega \sum_{b \in \mathcal{P}_{k'}^+(\mathfrak{g}^\omega)} N_{\gamma a}^b \dim_{G^\omega}(b) \mod M(G, k)
\]
\[
= \sum_{\gamma} \varphi_\gamma^\omega \dim_{G^\omega}(\gamma) \dim_{G^\omega}(a) \mod M(G, k)
\]
\[
= \dim_{G^\omega}(\lambda) \dim_{G^\omega}(a) .
\]
In the following two sections we shall give the details for how to define the maps \( \rho_i \), and prove the various statements above. We shall also be able to show that our charge solution is unique up to trivial rescalings.

2. The \( D_4 \) case with triality

In the \( D_4 \) case the relevant automorphism \( \omega \) is triality which maps the Dynkin labels \( \mu = (\mu_0; \mu_1, \mu_2, \mu_3, \mu_4) \) to \( (\mu_0; \mu_4, \mu_2, \mu_1, \mu_3) \). The set of exponents labelling the \( \omega \)-twisted Ishibashi states is therefore
\[
\mathcal{E}_k^\omega = \{(\mu_0; \mu_1, \mu_2, \mu_1, \mu_1) \in \mathbb{N}_0^5 \mid \mu_0 + 3\mu_1 + 2\mu_2 = k\} .
\]
The \( \omega \)-twisted boundary states are labelled by the level \( k \) integrable highest weights of the twisted Lie algebra \( \mathfrak{g}^\omega = D_4^{(3)} \), which are \( \mathcal{B}_k^\omega = \{(b_0; b_1, b_2) \in \mathbb{N}_0^3 \mid b_0 + 2b_1 + 3b_2 = k\} \). The states of lowest conformal weight of these representations form irreducible representations of the invariant subalgebra \( \mathfrak{g}^\omega = G_2 \) with highest weights \( (b_1, b_2) \). For this reason we propose that the corresponding D-brane charge is the Weyl dimension of these irreducible representations, \( i.e. \)
\[
q_b = \dim_{G_2}(b_1, b_2) = \dim_{G_2}(b) .
\]
In this section we shall prove that (2.2) solves the charge constraint
\[ \dim_{D_4}(\lambda) q_a = \sum_{b \in B_k^s} N_{\lambda a}^b q_b \] (2.3)
modulo \( M(G, k) \) and that this solution is unique (up to rescalings).

2.1 The solution

To show that (2.2) indeed solves the charge constraint (2.3) we trace the problem back to the case of untwisted branes in \( G_2 \). So we need to express \('twisted \( D_4 \) data' by \('untwisted \( G_2 \) data'. We first note, as already mentioned in section 1.1, that the integer \( M \) for \( G_2 \) at level \( k + 2 \) equals the integer for \( D_4 \) at level \( k \);
\[ M(D_4, k) = M(G_2, k + 2) = \frac{k + 6}{\gcd(k + 6, 60)} . \] (2.4)

As is also explained there, the key result [14] that we need to prove expresses the NIM-rep \( \mathcal{N} \) of \( D_4 \) in terms of the fusion rules of \( G_2 \). The first step in providing such a relation is the identification of the \( D_4 \) \( \psi \)-matrix at level \( k \) with the (rescaled) \( S \)-matrix of \( G_2 \) at level \( k + 2 \) (in the following we shall denote the \( S \)-matrix of \( G_2 \) by \( S' \) in order to distinguish it from the \( S \)-matrix of \( D_4 \))^3
\[ \tilde{\psi}_{\mu \nu} = \sqrt{3} S'_{\mu \nu} , \] (2.5)
where \( \tilde{\mu} \) is defined by
\[ \mu \mapsto \tilde{\mu} = (\mu_0, 3\mu_1 + 2, \mu_2) . \] (2.6)

Note that if \( \mu \in \mathcal{E}_k^+ \), then \( \tilde{\mu} \in \mathcal{P}_{k+2}^+(G_2) \equiv \mathcal{P}_{k+2} = \{ (\tilde{\mu}_1, \tilde{\mu}_2) \in \mathbb{N}_0^2 | \tilde{\mu}_1 + 2\tilde{\mu}_2 \leq k + 2 \} \). The identity (2.5) can be proven as follows. Define \( \kappa = k + 6 \) and \( c(x) = \cos(\frac{2\pi x}{3\kappa}) \). The \( \psi \)-matrix is given by (see [16]),
\begin{align*}
\psi_{\mu \nu} = \frac{2}{\kappa} & \left( c(pp' + 2pq' + 2qp' + qq') + c(2pp' + pq' + qp' - qq') \\
& + c(-pp' + pq' + q\nu + 2qq') - c(2pp' + pq' + q\nu + 2qq') \\
& - c(pp' + 2pq' - qp' + q\nu) - c(pp' - pq' + 2qp' + q\nu) \right) , \tag{2.7}
\end{align*}
where \( p = b_1 + b_2 + 2, q = b_2 + 1 \) and \( p' = 3\mu_1 + \mu_2 + 4, q' = \mu_2 + 1 \). On the other hand, if we define \( m = \lambda_1 + \lambda_2 + 2, n = \lambda_2 + 1, m' = \nu_1 + \nu_2 + 2 \) and \( n' = \nu_2 + 1 \), then the \( S \)-matrix of \( G_2 \) at level \( k + 2 \) is [22]
\[ S'_{\lambda \nu} = \frac{2}{\sqrt{3\kappa}} \left( c(2mm' + nn' + nn' + nn') + c(-mm' - 2mn' - nn' + nn') \\
+ c(-mm' + nn' - 2mn' - nn') - c(-mm' - 2mn' - 2mn' - nn') \\
- c(2mm' + nn' + nn' - nn') - c(-mm' + nn' + nn' + 2mn') \right) . \tag{2.8}
\]

[^3]: This relation was already noted in [10].
For (2.8) we also use the abbreviated notation

\[ S'_{\lambda \nu} = \frac{-2}{\sqrt{3\kappa}} (c(u_1) + c(u_2) + c(u_3) - c(u_4) - c(u_5) - c(u_6)) \, . \tag{2.9} \]

By comparing (2.7) and (2.8) one then easily proves (2.5).

Next we observe from (1.7) that in order to obtain fusion matrices of \( G_2 \) we also need to express the quotient \( \frac{S_{\lambda \mu}}{S_{0\mu}} \) in terms of \( G_2 \) \( S \)-matrices. The relevant relation is

\[ \frac{S_{\lambda \mu}}{S_{0\mu}} = \sum_{\gamma} \varphi_{\lambda}^\gamma S'_{\gamma \mu} \, . \tag{2.10} \]

Here, \( \varphi_{\lambda}^\gamma \) denotes the \( D_4 \supset G_2 \) branching rules; the most important ones are

\[ (1, 0, 0, 0) \rightarrow (1, 0) \oplus (0, 0) \quad \text{and} \quad (0, 1, 0, 0) \rightarrow (0, 1) \oplus (1, 0) \oplus (1, 0) \, . \tag{2.11} \]

The easiest way to prove (2.10) is to consider the explicit expressions for the fundamental \( D_4 \) representations of \( G_2 \).

Taking all of this together we can now write the \( D_4 \) NIM-rep as

\[ N_{\lambda \alpha}^b = \sum_{\mu \in \mathcal{E}_k^\omega} \psi_{\alpha \mu} \psi_{\beta \mu}^* \frac{S_{\lambda \mu}}{S_{0\mu}} = 3 \sum_{\gamma} \varphi_{\lambda}^\gamma \sum_{\mu \in \mathcal{E}_k^\omega} S'_{\alpha \mu} S'_{\beta \mu} \frac{S'_{\gamma \mu}}{S'_{0\mu}} \, . \tag{2.12} \]

Although this formula reminds one of the Verlinde formula, the last sum still does not give the \( G_2 \)-fusion rules as the range of summation for \( \tilde{\mu} \) is only a subset of \( \mathcal{P}_{k+2} \).

To resolve this problem we introduce the affine mappings

\[ \begin{align*}
\rho_0(b) &= (b_1, b_2) \\
\rho_1(b) &= (k - 2b_1 - 3b_2, 1 + b_1 + b_2) \\
\rho_2(b) &= (k + 1 - b_1 - 3b_2, b_2)
\end{align*} \tag{2.13} \]

which map the set \( \mathcal{B}_k^\omega \) of boundary states to disjoint subsets of \( \mathcal{P}_{k+2} = \mathcal{P}_{k+2}^+(G_2) \). They have the crucial property

\[ S'_{\rho_0(b) \nu} + S'_{\rho_1(b) \nu} - S'_{\rho_2(b) \nu} = \begin{cases} 
3 S'_b \nu & \text{if } \nu_1 = 2 \mod 3 \\
0 & \text{otherwise},
\end{cases} \tag{2.14} \]

where \( b \in \mathcal{B}_k^\omega \) and \( \nu \in \mathcal{P}_{k+2} \). This follows from the fact that the left hand side can be written as

\[ -\frac{\sqrt{3\kappa}}{2} (S'_b \nu + S'_{\rho_1(b) \nu} - S'_{\rho_2(b) \nu}) = (1 + \cos(v_1) + \cos(v_2))(c(u_1) - c(u_4)) \\
+ (1 + \cos(v_1) + \cos(v_3))(c(u_2) - c(u_5)) \\
+ (1 + \cos(v_2) + \cos(v_3))(c(u_3) - c(u_6)) \\
+ (\sin(v_1) + \sin(v_2))(s(u_1) + s(u_4)) \\
- (\sin(v_1) - \sin(v_3))(s(u_2) + s(u_6)) \\
- (\sin(v_2) + \sin(v_3))(s(u_3) + s(u_5)) \, . \tag{2.15} \]
where \( v_1 = \frac{2}{3} \pi (\nu_1 + 3\nu_2 + 4), v_2 = \frac{2}{3} \pi (2\nu_1 + 3\nu_2 + 5), v_3 = \frac{2}{3} \pi (\nu_1 + 1) \) and \( s(x) = \sin \left( \frac{\pi x}{3} \right) \).
(The \( u_i \) are defined as in (2.9).) This is easily seen to agree with the right hand side of (2.14).

Let \( \rho(B^c_k) = \rho_0(B_k^c) \cup \rho_1(B_k^c) \cup \rho_2(B_k^c) \) and \( \mathcal{R}_k = \mathcal{P}_{k+2} \setminus \rho(B_k^c) \). The special elements \( \nu \in \mathcal{P}_{k+2} \) in (2.14) which satisfy \( \nu_1 = 2 \mod 3 \) are precisely the images \( \nu = \tilde{\mu} \) under (2.6) of a suitable element \( \mu \) of \( \mathcal{E}_k^c \). The key relation (2.14), together with (2.12), therefore implies that the \( D_4 \) NIM-rep can be written as a sum of \( G_2 \) fusion matrices,

\[
N_{\lambda a}^{\le} = \sum_{\gamma} \varphi_{\lambda}^{\gamma} \sum_{\mu \in \mathcal{P}_{k+2}} S_{a\mu}^{\gamma} \frac{S_{\rho_0(b)\mu}^{\gamma} + S_{\rho_1(b)\mu}^{\gamma} - S_{\rho_2(b)\mu}^{\gamma}}{2}.
\]

where \( N_{\gamma} \) denote \( G_2 \) fusion matrices at level \( k + 2 \) and \( \varepsilon_i \) accounts for the signs. [Explicitly \( \varepsilon_0 = \varepsilon_1 = +1 \) and \( \varepsilon_2 = -1 \).] This is the relation (1.3) we proposed in section 1.1. Note that (2.16) is valid for all highest weights \( \lambda \) of \( D_4 \), not only for the ones appearing in \( \mathcal{P}_k^{+}(D_4) \). In fact we can continue \( N_{\lambda} \) and \( N_{\gamma} \) outside of the usual domain by rewriting the ratios of \( S \)-matrices appearing in (2.12) as characters of the finite Lie algebras.

According to the argument given in section 1.1, there is only one further ingredient we need to show. This concerns the behaviour of the \( G_2 \)-Weyl dimensions under the maps \( \rho_i \), and is summarised in the relations (1.10) and (1.11). Thus we need to prove that

\[ \dim_{G_2}(\rho_i(b)) = \varepsilon_i \dim_{G_2}(b) \mod M(G_2, k + 2) \] (2.17)

and that any element \( r \in \mathcal{R}_k \) satisfies

\[ \dim_{G_2}(r) = 0 \mod M(G_2, k + 2) \] (2.18)

The dimension of a \( G_2 \) representation \( (b_1, b_2) \) is given by

\[ \dim_{G_2}(b_1, b_2) = \frac{1}{120} (b_1 + 1)(b_2 + 1)(b_1 + b_2 + 2)(b_1 + 2b_2 + 3)(b_1 + 3b_2 + 4)(2b_1 + 3b_2 + 5) \]

To prove (2.17) we find by explicit computation that

\[ \dim_{G_2}(\rho_i(b)) = \varepsilon_i \dim_{G_2}(b) + \frac{M(G_2, k + 2)}{F} p^5(b) \] (2.19)

where \( p^5(b) \) denotes a \( k \) and \( \rho_i \)-dependent polynomial of order 5 in the variables \( b_1, b_2 \) with integer coefficients, and \( F = \frac{120}{\gcd(k+6,60)} \). Thus it remains to show that \( \frac{p^5}{F} \) is an integer. If \( 8 \) does not divide \( k + 6 \), then \( M(G_2, k + 2) \) and \( F \) are coprime. Since \( \frac{M(G_2, k + 2)}{F} \) is an integer, \( \frac{p^5}{F} \) has to be an integer as well and we are done. If \( 8 \) is a divisor of \( k + 6 \), then \( F \) and \( M(G_2, k + 2) \) have greatest common divisor 2. The result then follows provided that \( p^5 \) is even, which is easily verified.
To show (2.18) we first have to identify the elements of $R_k$. It is convenient to write this set as the (disjoint) union of the two subsets $R^1_k$ and $R^2_k$. The first of them is defined by

$$R^1_k = \{(b_1, b_2) \in P_{k+2} \mid (b_1, b_2) = (k + 2 - 3j, j), \ j \in \mathbb{N}_0\}.$$  \hspace{1cm} (2.20)

The set $R^2_k \equiv R_k \setminus R^1_k$ depends in a more complicated manner on $k$. To describe it explicitly we therefore distinguish the three cases:

- $k = 0 \mod 3$
  $$R^2_k = \{(2 + 3j, k/3 - 1 - 2j) \in P_{k+2}, \ j \in \mathbb{N}_0\}$$

- $k = 1 \mod 3$
  $$R^2_k = \{(0, (k + 2)/3) \cup \{(1 + 3j, (k - 1)/3 - 2j) \in P_{k+2}, \ j \in \mathbb{N}_0\}$$

- $k = 2 \mod 3$
  $$R^2_k = \{(0, (k + 1)/3) \cup \{(3 + 3j, (k + 1)/3 - 2(j + 1)) \in P_{k+2}, \ j \in \mathbb{N}_0\}.$$ 

For any $r \in R_k$ one then easily checks that

$$\dim_{G_2}(r) = \frac{M}{F}p^5(j)$$ \hspace{1cm} (2.21)

with some polynomial $p^5$ in $j$ of order 5. One finds that the polynomials $p^5(j)$ are even whenever 8 divides $k + 6$. Using the same arguments as above, this then finishes the proof of (2.18). It remains to check that we have identified the complete set $R_k$ correctly. Because $\rho_i(B_k^\omega) \cap \rho_j(B_k^\omega) = \emptyset$ for $i \neq j$ we have $|\rho(B_k^\omega)| = 3|B_k^\omega|$. In order to see that $P_{k+2} = \rho(B_k^\omega) \cup R_k$, it is therefore sufficient to count the number of elements of the different sets. One easily finds

$$|P_{k+2}| = \begin{cases} \frac{1}{4}(k + 4)^2 & k \text{ even} \\ \frac{1}{4}(k + 3)(k + 5) & k \text{ odd} \end{cases}$$

as well as

$$|R_k| = \begin{cases} \frac{1}{2}(k + 2) & k = 0 \mod 6 \\ \frac{1}{2}(k + 4) & k = 2, 4 \mod 6 \\ \frac{1}{2}(k + 3) & k = 3 \mod 6 \end{cases}$$

$$|B_k^\omega| = \begin{cases} \frac{1}{12}k^2 + \frac{1}{2}k + 1 & k = 0 \mod 6 \\ \frac{1}{12}(k + 2)(k + 4) & k = 2, 4 \mod 6 \\ \frac{1}{12}(k + 3)^2 & k = 3 \mod 6 \end{cases}$$

Using these formulae it is then easy to show that $|P_{k+2}| = |\rho(B_k^\omega)| + |R_k|$. This completes the proof.
2.2 Uniqueness

It remains to prove that the solution we found is unique up to an overall rescaling of the charge. To this end we show that any solution of the charge constraint modulo some integer \( M' \) satisfies the relation

\[
q_a = \dim(a) q_0 \mod M',
\]

and thus is obtained from our solution (2.2) by scaling with the factor \( q_0 \).

To prove (2.22) we first want to show that any \( G_2 \) representation \( a \) can be obtained as restriction of a linear combination of \( D_4 \) representations \( \lambda_j \) with integer coefficients \( z_j \). We explicitly allow negative multiplicities and write formally

\[
a = \bigoplus_j z_j \lambda_j|_{G_2}.
\]

Obviously it is sufficient to prove this for the fundamental representations. Looking at the branching rules (2.11) we see that the representation \((1,0)\) appears in the decomposition of \((1,0,0,0)\), so we can write

\[
(1,0) = \left( (1,0,0,0) - (0,0,0,0) \right)|_{G_2}.
\]

Similarly, we can express \((0,1)\) as a restriction because it appears exactly once in the decomposition of \((0,1,0,0)\) together only with \((1,0)\) (see (2.11)).

Now consider a boundary state labelled by \( a \). We can use (2.16) to write

\[
\dim_{G_2}(a) q_0 = \sum_j z_j \dim_{D_4}(\lambda_j) q_0
\]

\[
\quad = \sum_{j,b} z_j N_{\lambda_j} b |g_b\mod M'
\]

\[
\quad = \sum_{i,j,\gamma,b} z_j \varepsilon_i \varphi_{\lambda_j} \gamma N_{\gamma} \rho_i(b) |g_b
\]

\[
\quad = \sum_{i,b} \varepsilon_i N_{a_0} \rho_i(b) |g_b
\]

\[
= q_a.
\]

(2.23)

In the last step we used the fact that \( \rho_i(B_\ell^c) \) and \( B_\ell^c \) are disjoint for \( i \neq 0 \), so that only \( i = 0 \) contributes. This concludes the proof of (2.22).

3. The \( E_6 \) case with charge conjugation

The analysis for the case of \( E_6 \) is fairly similar to the \( D_4 \) case discussed in the previous section, and we shall therefore be somewhat briefer. For \( E_6 \) the invariant subalgebra under charge conjugation is \( \bar{g}^c = F_4 \). Again we have the identity

\[
M(E_6,k) = M(F_4,k + 3) = \frac{k + 12}{\gcd(k + 12, 2^3 \cdot 3^2 \cdot 5 \cdot 7 \cdot 11)}.
\]

(3.1)

\[\text{Note that the charge constraint (2.4), as well as the expression (2.11) for the NIM-rep is valid also for highest weights } \lambda \text{ which are not in } P_k^+(D_4).\]
As before we therefore expect that

\[ \dim_{E_6}(\lambda) = \sum_{b \in B_6^\omega} N_{\lambda b} \dim_{F_4}(b) \mod M(F_4, k+3), \]  

(3.2)

where

\[ \dim_{F_4}(b) = \dim_{F_4}(b). \]  

(3.3)

The order 2 automorphism \( \omega \) of \( E_6 \) maps the Dynkin labels \( (\mu_0; \mu_1, \mu_2, \mu_3, \mu_4, \mu_5, \mu_6) \) to \( (\mu_0; \mu_5, \mu_4, \mu_3, \mu_2, \mu_1, \mu_6) \), and thus the set of exponents is

\[ E_6^\omega = \{ (\mu_0; \mu_1, \mu_2, \mu_3, \mu_2, \mu_1, \mu_6) \in \mathbb{N}_0^7 | \mu_0 + 2\mu_1 + 4\mu_2 + 3\mu_3 + 2\mu_6 = k \} . \]  

(3.4)

The twisted algebra here is \( E_6^{(2)} \). The set of boundary states at level \( k \) is explicitly given by \( B_6^\omega = \{ (b_0; b_1, b_2, b_3, b_4) \in \mathbb{N}_0^4 | b_0 + 2b_1 + 3b_2 + 4b_3 + 2b_4 = k \} \). As in the last section, it is possible to identify the \( \psi \)-matrix of \( E_6 \) at level \( k \) with the \( S \)-matrix of \( F_4 \) at level \( k + 3 \) (see also [16]),

\[ \psi_{b\mu} = 2 S'_{b\tilde{\mu}}, \]  

(3.5)

where \( \tilde{\mu} \) is now defined by

\[ \mu \mapsto \tilde{\mu} = (\mu_0; 2\mu_1 + 1, 2\mu_2 + 1, \mu_3, \mu_6). \]  

(3.6)

As before we observe that if \( \mu \in E_6^\omega \), then \( \tilde{\mu} \in P^+_k(F_4) \equiv P_{k+3}, \) where the latter is explicitly defined as \( P_{k+3} = \{ (\tilde{\mu}_1, \tilde{\mu}_2, \tilde{\mu}_3, \tilde{\mu}_4) \in \mathbb{N}_0^4 | \tilde{\mu}_1 + 2\tilde{\mu}_2 + 3\tilde{\mu}_3 + 2\tilde{\mu}_4 \leq k + 3 \} \). Furthermore, we can express ratios of \( S \)-matrices of \( E_6 \) by those of \( F_4 \),

\[ \frac{S_{\lambda\mu}}{S_{0\mu}} = \sum_{\gamma} \varphi_{\lambda \gamma} \frac{S'_{\gamma\tilde{\mu}}}{S'_{0\tilde{\mu}}}. \]

Here \( S \) denotes the \( E_6 \) \( S \)-matrix at level \( k \), \( S' \) is the \( F_4 \) \( S \)-matrix at level \( k + 3 \), and \( \varphi_{\lambda \gamma} \) describes the branching \( E_6 \supset F_4 \); for the six fundamental representations of \( E_6 \) the branching rules are

\[ (1, 0, 0, 0, 0, 0) \simeq (0, 0, 0, 0, 1, 0) \rightarrow (1, 0, 0, 0) \oplus (0, 0, 0, 0) \]
\[ (0, 1, 0, 0, 0, 0) \simeq (0, 0, 0, 1, 0, 0) \rightarrow (0, 1, 0, 0) \oplus (0, 0, 0, 1) \oplus (1, 0, 0, 0) \]
\[ (0, 0, 1, 0, 0, 0) \rightarrow (0, 0, 1, 0) \oplus (1, 0, 0, 1) \oplus 2 \cdot (0, 1, 0, 0) \oplus (0, 0, 0, 1) \]
\[ (0, 0, 0, 0, 1, 0) \rightarrow (0, 0, 0, 1) \oplus (1, 0, 0, 0). \]  

(3.7)

The relevant affine mappings are in this case

\[ \rho_0(b) = (b_1, b_2, b_3, b_4) \]
\[ \rho_1(b) = (k - 2b_1 - 3b_2 - 4b_3 - 2b_4, 1 + b_1 + b_2, b_3, b_4) \]
\[ \rho_2(b) = (k + 1 - b_1 - 3b_2 - 4b_3 - 2b_4, b_2, b_3, b_4) \]
\[ \rho_3(b) = (k - 2b_1 - 3b_2 - 4b_3 - 2b_4, b_1, b_2 + b_3 + 1, b_4). \]  

(3.8)
which map boundary states at level $k$ to dominant weights of $F_4$ at level $k + 3$, i.e. to elements of $\mathcal{P}_{k+3}$. There is a similar identity to (2.14) for the $S$-matrices

$$S'_{\rho_0(b)\nu} + S'_{\rho_1(b)\nu} - S'_{\rho_2(b)\nu} - S'_{\rho_3(b)\nu} = \begin{cases} 4 S'_{b\nu} & \text{if } \nu_1 = \nu_2 = 1 \mod 2 \\ 0 & \text{otherwise} \end{cases} \quad (3.9)$$

where $b \in \mathcal{B}_k^\omega$ and $\nu \in \mathcal{P}_{k+3}$. Again, the elements which satisfy $\nu_1 = \nu_2 = 1 \mod 2$ are precisely the images $\nu = \tilde{\mu}$ of an element $\mu$ of $\mathcal{E}_k^\omega$ under the mapping (3.6). By $\rho(\mathcal{B}_k^\omega)$ we denote the union of the images of $\mathcal{B}_k^\omega$ under the maps $\rho_i$, $\rho(\mathcal{B}_k^\omega) = \bigcup_{i=0}^{3} \rho_i(\mathcal{B}_k^\omega)$. The elements of $\mathcal{P}_{k+3}$ which are not reached by the maps form the set $\mathcal{R}_k = \mathcal{P}_{k+3} \setminus \rho(\mathcal{B}_k^\omega)$.

Using essentially the same arguments as for the case of $D_4$ discussed in the last section, we can then show that the $E_6$ NIM-rep can be expressed in terms of $F_4$ fusion matrices as

$$N_{\lambda a}^{\rho_i(b)} = \sum_\gamma \varphi_\lambda^\gamma \left( N_{\gamma a}^{\rho_0(b)} + N_{\gamma a}^{\rho_1(b)} - N_{\gamma a}^{\rho_2(b)} - N_{\gamma a}^{\rho_3(b)} \right) = \sum_{i=0}^{3} \sum_\gamma \varepsilon_i \varphi_\lambda^\gamma N_{\gamma a}^{\rho_i(b)} , \quad (3.10)$$

where the $\varepsilon_i$ account for the signs. [Explicitly, $\varepsilon_1 = \varepsilon_2 = +1$ and $\varepsilon_3 = \varepsilon_4 = -1$.] Following the argument of section 1.1, it thus only remains to show that

$$\dim_{F_4}(\rho_i(b)) = \varepsilon_i \dim_{F_4}(b) \mod M(F_4, k + 3) , \quad (3.11)$$

and for all $r \in \mathcal{R}_k$

$$\dim_{F_4}(r) = 0 \mod M(F_4, k + 3) . \quad (3.12)$$

To prove equation (3.11) we note that

$$\dim_{F_4}(\rho_i(b)) = \varepsilon_i \dim_{F_4}(b) + \frac{M(F_4, k + 3)}{F} p^{23}(b) \quad (3.13)$$

where

$$F = \frac{2^{15} \cdot 3^7 \cdot 5^4 \cdot 7^2 \cdot 11}{\gcd(k + 12, 2^3 \cdot 3^2 \cdot 5 \cdot 7 \cdot 11)} \quad (3.14)$$

and $p^{23}$ is a $k$ and $\rho_i$-dependent polynomial (with integer coefficients) of degree 23 in the labels $b_i$. Now $M(F_4, k + 3)$ and $F$ are coprime whenever $2^4$, $3^3$, $5^2$ and $7^2$ do not divide $k + 12$; in this case (3.11) is proven as before. Otherwise the analysis is more involved and many cases would have to be distinguished. We have not attempted to analyse all of them in detail, but we have performed a numerical check up to fairly high levels. This seems satisfactory, given that the identities for $M(E_6, k)$ and $M(F_4, k)$ have also only be determined numerically.

Finally, we need to show the identity (3.12). This requires a good description of the set $\mathcal{R}_k$. Here it is convenient to write it as the union of four disjoint subsets which are
defined by

\[
\mathcal{R}_k^1 = \begin{cases} 
    \{ b \in \mathcal{P}_{k+3} | b = (1 + 2j_1, j_2, j_3, (k + 2)/2 - j_1 - j_2 - 2j_3) \} & \text{k even} \\
    \{ b \in \mathcal{P}_{k+3} | b = (2j_1, j_2, j_3, (k + 3)/2 - j_1 - j_2 - 2j_3) \} & \text{k odd}
\end{cases}
\]

\[
\mathcal{R}_k^2 = \begin{cases} 
    \{ b \in \mathcal{P}_{k+3} | b = (2j_1, 2j_2, j_3, (k + 2)/2 - j_1 - 3j_2 - 2j_3) \} & \text{k even} \\
    \{ b \in \mathcal{P}_{k+3} | b = (1 + 2j_1, 2j_2, j_3, (k + 1)/2 - j_1 - 3j_2 - 2j_3) \} & \text{k odd}
\end{cases}
\]

\[
\mathcal{R}_k^3 = \begin{cases} 
    \{ b \in \mathcal{P}_{k+3} | b = (1 + 2j_1, 1 + 2j_2, j_3, (k - 2)/2 - j_1 - 3j_2 - 2j_3) \} & \text{k even} \\
    \{ b \in \mathcal{P}_{k+3} | b = (2j_1, 1 + 2j_2, j_3, (k - 1)/2 - j_1 - 3j_2 - 2j_3) \} & \text{k odd}
\end{cases}
\]

\[
\mathcal{R}_k^4 = \begin{cases} 
    \{ b \in \mathcal{P}_{k+3} | b = (j_1, 1 + 2j_2, j_3, (k - 2)/2 - j_1 - 3j_2 - 2j_3) \} & \text{k even} \\
    \{ b \in \mathcal{P}_{k+3} | b = (j_1, 2j_2, j_3, (k + 1)/2 - j_1 - 3j_2 - 2j_3) \} & \text{k odd}
\end{cases}
\]

where \((j_1, j_2, j_3) \in \mathbb{N}_0^3\). The same arguments as before show that the elements \(r\) in these sets satisfy \(\dim_{F_4}(r) = 0 \mod M(F_4, k + 3)\). Again, this is proven only if \(k + 12\) is not divisible by \(2^4, 3^3, 5^2\) or \(7^2\); for the other levels we have only performed numerical checks.

Finally, by counting the elements of the different sets we can confirm (as before) that we have correctly identified the set \(\mathcal{R}_k\). This completes the proof for the case of \(E_6\).

### 3.1 Uniqueness

The proof of uniqueness is analogous to the \(D_4\) case. It only remains to show that all fundamental representations of \(F_4\) can be obtained as restrictions of \(E_6\) representations. From the branching rules (3.7) we see immediately that this is true for \((1, 0, 0, 0)\), \((0, 0, 0, 1)\) and \((0, 1, 0, 0)\). The remaining fundamental representation \((0, 0, 1, 0)\) appears in the decomposition of \((0, 0, 1, 0, 0, 0)\), but it comes together with \((1, 0, 0, 1)\). The latter representation can be obtained from the other fundamentals by the \(F_4\) tensor product

\[
(1, 0, 0, 0) \otimes (0, 0, 0, 1) \rightarrow (1, 0, 0, 1) \oplus (1, 0, 0, 0) \oplus (0, 1, 0, 0)
\]

Hence, also \((0, 0, 1, 0)\) can be written in terms of the restriction of \(D_4\)-representations.

**Note added:** While we were in the process of writing up this paper we became aware of [23] which contains closely related work.

**Acknowledgements:** This research has been partially supported by the Swiss National Science Foundation and the Marie Curie network ‘Constituents, Fundamental Forces and Symmetries of the Universe’ (MRTN-CT-2004-005104).
