Human genetic variants predicted to cause loss-of-function of protein-coding genes (pLoF variants) provide natural in vivo models of human gene inactivation and can be valuable indicators of gene function and the potential toxicity of therapeutic inhibitors targeting these genes1,2. Gain-of-kinase-function variants in LRRK2 are known to significantly increase the risk of Parkinson’s disease3,4, suggesting that inhibition of LRRK2 kinase activity is a promising therapeutic strategy. While preclinical studies in model organisms have raised some on-target toxicity concerns1,2,25, the biological consequences of LRRK2 inhibition have not been well characterized in humans. Here, we systematically analyze pLoF variants in LRRK2 observed across 141,456 individuals sequenced in the Genome Aggregation Database (gnomAD), 49,960 exome-sequenced individuals from the UK Biobank and over 4 million participants in the 23andMe genotyped dataset. After stringent variant curation, we identify 1,455 individuals with high-confidence pLoF variants in LRRK2. Experimental validation of three variants, combined with previous work25, confirmed reduced protein levels in 82.5% of our cohort. We show that heterozygous pLoF variants in LRRK2 reduce LRRK2 protein levels but that these are not strongly associated with any specific phenotype or disease state. Our results demonstrate the value of large-scale genomic databases and phenotyping of human loss-of-function carriers for target validation in drug discovery.

New therapeutic strategies are desperately needed in Parkinson’s disease (PD), one of the most common age-related neurological diseases, which affects about 1% of people over the age of 60 years13,14. Around 30% of familial and 3–5% of sporadic PD cases have been linked to a genetic cause13. LRRK2 missense variants account for a large fraction of cases, including high-penetrance variants13, moderately penetrant variants such as G2019S13 and risk factors identified in genome-wide association studies13. Although the precise

Fig. 1 | Annotation and curation of candidate LRRK2 pLoF variants. a, Flow chart showing the variant filtering and curation of candidate LRRK2 pLoF variants in the gnomAD, UK Biobank and 23andMe cohorts. Of the 1,103 carriers identified in 23andMe, 749 were confirmed by Sanger sequencing with the remainder untested. b, The ancestry distribution of LRRK2 pLoF variant carriers in gnomAD. AFR, African/African American; AMR, American/Latino; ASJ, Ashkenazi Jewish; EAS, East Asian; FIN, Finnish; NFE, non-Finnish European; SAS, South Asian. The pLoF variants seen more than ten times appear in color with remaining variants in gray. LRRK2 pLoF variants are mostly individually extremely rare (less than 1 in 10,000 carrier frequency), with the exception of two nonsense variants almost exclusively restricted to the admixed AMR population (Cys1313Ter and Arg1725Ter) and two largely NFE-specific variants (Leu2063Ter and Arg772Ter). All variant protein descriptions are with respect to ENSP00000298910.7.

c, Schematic of the LRRK2 gene with pLoF variant carriers in gnomAD (gray bars) and UK Biobank (blue bars). The 51 exons are shown as rectangles colored by protein domain, with the remaining exons in gray. The three variants genotyped in the 23andMe cohort are annotated with their sample count in black text.
requires very large collections of genetically and phenotypically characterized individuals, combined with deep curation of the target gene and candidate variants\(^\text{[32]}\). Although previous studies of pLoF variants in LRRK2 have found no association with risk of PD\(^\text{[16]}\), no study has assessed their broader phenotypic consequences.

We identified LRRK2 pLoF variants and assessed associated phenotypic changes in three large cohorts of genetically characterized individuals. First, we annotated LRRK2 pLoF variants in two large sequencing cohorts: the gnomAD v.2.1.1 dataset, which contains 125,748 exomes and 15,708 genomes from unrelated individuals\(^\text{[2]}\) and 46,062 exome-sequenced unrelated European individuals from the UK Biobank\(^\text{[32]}\). We identified 633 individuals in gnomAD and 258 individuals in the UK Biobank with 150 unique candidate LRRK2 loss-of-function (LoF) variants, a combined carrier frequency of 0.48\%. All variants were observed only in the heterozygous state. Compared to the spectrum observed across all genes, LRRK2 is not significantly depleted for pLoF variants in gnomAD (LoF observed/expected upper bound fraction\(^\text{[9]}\) \(= 0.64\)).

We manually curated the 150 identified variants to remove those of low quality or with annotation errors suggesting that they are unlikely to cause true LoF (Fig. 1a and Supplementary Tables 1 and 2). We removed 16 variants identified as low confidence by the LoF transcript effect estimator (LOFTEE); 6 variants in 409 individuals) or manually curated as low quality or unlikely to cause LoF (10 variants in 129 individuals). One additional individual was excluded from the UK Biobank cohort as they carried both a pLoF variant and the G2019S risk allele.

Our final dataset comprised 255 gnomAD individuals and 97 UK Biobank individuals with 134 unique high-confidence pLoF variants (Fig. 1a) and an overall carrier frequency of 0.19\%; less than half the frequency estimated from uncurated variants, reaffirming the importance of thorough curation of candidate LoF variants\(^\text{[32]}\). A subset of 25 gnomAD samples with 19 unique LRRK2 pLoF variants with DNA available were all successfully validated by Sanger sequencing (Supplementary Table 3).

Second, we examined LRRK2 pLoF variants in over 4 million consented and array-genotyped research participants from the personal genetics company 23andMe. Eight putative (LOFTEE high confidence) LRRK2 LoF variants were identified. After manual curation, all putative carriers of each variant were submitted for validation by Sanger sequencing and variants with <5 confirmed carriers were excluded. The resulting cohort comprised 749 individuals, each a Sanger-confirmed carrier for one of three pLoF variants (Fig. 1a and Supplementary Table 4). The high rate of Sanger confirmation for rs183902574 (>98\%) allowed confident addition of 354 putative carriers of rs183902574, from expansion of the 23andMe dataset, without Sanger confirmation. Analyses with and without these genotyped-only carriers were not significantly different (Supplementary Table 5). Across the two most frequent pLoF alleles we observed an extremely small number (<5) of sequence-confirmed homozygotes; however, given the very small number of observations, we can make no robust inference, except that homozygous inactivation of LRRK2 seems compatible with life. For the remainder of this manuscript we focus on heterozygous pLoF carriers.

The three combined datasets provide a total of 1,455 carrier individuals with 134 unique LRRK2 pLoF variants. These variants are found across all major continental populations (Fig. 1b and Extended Data Fig. 1) and show neither any obvious clustering along the length of the LRRK2 protein, nor specific enrichment or depletion in any of the known annotated protein domains (chi squared \(P = 0.22\); Fig. 1c), consistently with signatures of true LoF\(^\text{[32]}\).

To confirm that LRRK2 pLoF variants result in reduced LRRK2 protein levels, we analyzed total protein lysates from cell lines with three unique pLoF variants. We obtained lymphoblastoid cell lines (LCLs) from two families with naturally occurring heterozygous LoF variants and a third variant was CRISPR/Cas9-engineered into embryonic stem cells (Extended Data Fig. 2), which were differentiated into cardiomyocytes. In all instances, LRRK2 protein levels were visibly reduced compared to noncarrier controls (Fig. 2). These results agree with a previous study which assessed three separate pLoF variants and found significantly reduced LRRK2 protein levels\(^\text{[10]}\). Together, these six functionally validated variants represent 82.5\% of pLoF carriers in this study (1,201 of 1,455). Although heterozygous pLoF carriers have LRRK2 protein remaining, we believe that this state represents a plausible genetic model for therapeutic inhibition of LRRK2, as target engagement by pharmacological inhibitors is unlikely to be complete.

We next sought to determine whether lifelong lowering of LRRK2 protein levels through LoF results in an apparent reduction in lifespan. We found no significant difference between the age distribution of LRRK2 pLoF variant carriers and noncarriers in either the gnomAD or 23andMe datasets (two-sided Kolmogorov–Smirnov \(P = 0.085\) and 0.46 respectively; Fig. 3a), suggesting no major impact on longevity, though we note that this analysis is based on age at sample collection, which is not equivalent to longevity and at current sample sizes we are only powered to detect a strong effect (Supplementary Table 6).

For a subset of studies within gnomAD, phenotype data are available from study or national biobank questionnaires or from linked electronic health records (Methods). We manually reviewed these records for all 60 of the 255 gnomAD LRRK2 pLoF carriers with available data and recorded any phenotypes affecting the lung, liver, kidney, cardiovascular system, nervous system, immunity and cancer (Supplementary Table 7). We found no over-representation of any phenotype or phenotype category in LRRK2 pLoF carriers.
The 23andMe dataset includes self-reported data for thousands of phenotypes across a diverse range of categories. We performed a phenome-wide association study comparing \( LRRK2 \) pLoF carriers to noncarriers for 366 health-related traits and found no significant association between any individual phenotype and carrier status (Fig. 3b). In particular, we found no significant associations with any lung, liver or kidney phenotypes (Supplementary Tables 5 and 8).

The UK Biobank resource includes measurements for 30 blood serum and four urine biomarkers. We found no difference in any of these biomarkers between pLoF carriers and noncarriers (Supplementary Table 9 and Supplementary Fig. 1). In particular, there was no difference between carriers and noncarriers for urine biomarkers transformed into clinical measures of kidney function (Fig. 4a and Methods) and no difference in six blood biomarkers commonly used to assess liver function (Fig. 4c). We also observed no difference in spirometry measurements of lung function (Fig. 4b).

We grouped self-reported disease diagnoses in UK Biobank individuals into categories corresponding to the organ system and/or mechanism (Supplementary Table 10). We observed no enrichment for any of these phenotype groups in \( LRRK2 \) pLoF carriers when compared to noncarriers (Supplementary Table 11). We also mined ICD10 codes from hospital admissions and death records for any episodes relating to lung, liver and kidney phenotypes, removing any with a likely infectious or other external cause (Supplementary Table 12 and Methods) and identified six pLoF carriers with ICD10 codes relating to these organ systems (6.19%), compared to 4,536 noncarriers (9.87%; Supplementary Tables 13 and 14).

Our results indicate that approximately 1 in every 500 humans is heterozygous for a pLoF variant in \( LRRK2 \), resulting in a systemic lifelong decrease in \( LRRK2 \) protein levels and that this partial inhibition has no discernible effect on survival or health at current sample sizes. These results suggest that partial reduction of \( LRRK2 \) protein in humans is unlikely to result in the severe phenotypes observed in knockout animals. This is consistent with initial phase 1 studies of therapeutic \( LRRK2 \) kinase inhibitors, which have shown promising safety results\(^2\), but are not yet able to address long-term, on-target pharmacology-related safety profiles.

The rarity of pLoF variants in \( LRRK2 \), combined with the relatively low prevalence of PD, prevents direct assessment of whether \( LRRK2 \) inhibition reduces the incidence of PD with current sample sizes (Supplementary Table 5). Future cohorts with many more sequenced and phenotyped individuals (probably millions of...
LRRK2 levels are lowered by ~80% using siRNA34,35. Additionally, shown that Rab10 phosphorylation is markedly reduced when pLoF variants reduce kinase activity and instead take reduc-

pLoF variants not genotyped noncarriers could be carriers of data; this means that a subset of the 23andMe individuals treated as due to the availability of targeted genotyping rather than sequencing of powered to detect a strong effect on lifespan. Our ascertainment and participants are relatively young compared to the typical age only age at recruitment, which is an imperfect proxy for lifespan self-reported questionnaires. Both 23andMe and gnomAD record effects of chronic administration of LRRK2 inhibitors.

We acknowledge multiple limitations to this work. First, we relied on heterogeneous phenotype data mostly derived from self-reported questionnaires. Both 23andMe and gnomAD record only age at recruitment, which is an imperfect proxy for lifespan and participants are relatively young compared to the typical age of onset for PD. In addition, at current sample sizes we are only powered to detect a strong effect on lifespan. Our ascertainment of LRRK2 pLoF variants in 23andMe was necessarily incomplete, due to the availability of targeted genotyping rather than sequencing data; this means that a subset of the 23andMe individuals treated as noncarriers could be carriers of LRRK2 pLoF variants not genotyped or imputed in this dataset. We have not directly assessed whether LRRK2 pLoF variants reduce kinase activity and instead take reduction in protein levels as a proxy. Previous studies have, however, shown that Rab10 phosphorylation is markedly reduced when LRRK2 levels are lowered by ~80% using siRNA34,35. Additionally, lifelong LoF of LRRK2 may not be equivalent to therapeutic inac-

Fig. 4 | LRRK2 pLoF carriers do not have impaired lung, liver or kidney function. For all plots, points for individual pLoF carriers are shown in teal and noncarriers in gray. The mean and 1×s.d. are represented by the black circle and line. a, Urine biomarkers albumin and creatinine were transformed into two clinical markers of kidney function (Methods). No pLoF carriers showed signs of severely impaired kidney function. ACR, albumin to creatinine ratio. b, Z scores of age-, sex- and height-corrected spirometry measures of lung function36. FVC, forced vital capacity; FEV1, forced expiratory volume in 1 s. c, Blood serum biomarkers of liver function. The plots for alkaline phosphatase, alanine aminotransferase, aspartate aminotransferase, bilirubin and creatinine were top-truncated, removing 47, 29, 92, 8 and 27 noncarriers respectively. The violin plots and summary statistics were calculated on the full dataset. All pLoF carriers are within each plot area.

samples) will be required to answer this question. As such, our study focuses entirely on whether partial genetic LRRK2 inactivation has broader phenotypic consequences that might correspond to adverse effects of chronic administration of LRRK2 inhibitors.

We acknowledge multiple limitations to this work. First, we relied on heterogeneous phenotype data mostly derived from self-reported questionnaires. Both 23andMe and gnomAD record only age at recruitment, which is an imperfect proxy for lifespan and participants are relatively young compared to the typical age of onset for PD. In addition, at current sample sizes we are only powered to detect a strong effect on lifespan. Our ascertainment of LRRK2 pLoF variants in 23andMe was necessarily incomplete, due to the availability of targeted genotyping rather than sequencing data; this means that a subset of the 23andMe individuals treated as noncarriers could be carriers of LRRK2 pLoF variants not genotyped or imputed in this dataset. We have not directly assessed whether LRRK2 pLoF variants reduce kinase activity and instead take reduction in protein levels as a proxy. Previous studies have, however, shown that Rab10 phosphorylation is markedly reduced when LRRK2 levels are lowered by ~80% using siRNA34,35. Additionally, lifelong LoF of LRRK2 may not be equivalent to therapeutic inactivation later in life if biological compensation occurs. Finally, the low-frequency of naturally occurring LRRK2 pLoF variants results in a relatively small number of carriers that could be assessed for each biomarker and phenotype, meaning that we are not well pow-

This study provides an important proof of principle for the value of very large genetically and phenotypically characterized cohorts, combined with thorough variant curation, in exploring the safety profile of candidate drug targets. Over the coming years, the availability of complete exome or genome sequence data for hundreds of thousands of individuals who are deeply phenotyped and/or available for genotype-based recontact studies, combined with deep curation and experimental validation of candidate pLoF variants, will provide powerful resources for therapeutic target validation as well as broader studies of the biology of human genes.

Methods
gnomAD variant annotation and curation. The gnomAD resource, including both sample and variant quality control (including sample ancestry assignment), is fully described in our companion paper. Analysis was conducted using gnomAD v2.1.1. Putative LoF variants were defined as stop-gained, frameshift or essential splice site (splice donor or splice acceptor) as annotated by the Ensembl Variant Effect Predictor.

Variants were included if they were annotated as LoF on any of the three high-confidence GENCODE annotated protein-coding transcripts that are expressed in the lung, liver or kidney. All variants also underwent transcript expression-aware annotation which evaluates cumulative expression status of transcripts harboring a variant in the Genotype Tissue Expression (GTEx) project dataset. All high-confidence variants were found in exons with high evidence of expression across all relevant tissues in GTEx. In addition, all were high-confidence pLoF on the canonical transcript, which is the only transcript to include the kinase domain. Variants were filtered out if they were flagged as low confidence by LOFTEE.

For the remaining variants, manual curation was performed, including inspection of variant quality metrics, read distribution and the presence of nearby variants using the integrative genome viewer and splice-site prediction algorithms using Alamut.

A single splice-site variant (12–40626187-T-C), found in 77 gnomAD carriers, was identified in an individual with RNA-seq data in the GTEx project. The RNA-seq reads were manually inspected to look for any effect on splicing. Assessing the read distribution of a linked heterozygous variant in this individual showed convincingly that the variant has no discernible effect on transcript splicing (Extended Data Fig. 3). All available tissues were assessed with reads from lung tissue shown in Extended Data Fig. 3. The variant was also identified in eight UK Biobank carriers and in 23andMe and was similarly excluded from these cohorts.

This study complied with all relevant ethical regulations and was overseen by the Broad Institute’s Office of Research Subject Protection and the Partners Human Research Committee. Informed consent was obtained from all participants.

Sanger validation of gnomAD variant carriers. Sanger validation was performed on genomic DNA derived from peripheral blood under the following PCR conditions: 98 °C 2 min; 30 cycles 20 s 98 °C, 20 s 54 °C, 1 min 72 °C; 3 min 72 °C using Herculase II Fusion DNA polymerase (Agilent, 600679). PCR products (5 μl) were analyzed on a 2% agarose gel and the remaining product was purified with the Qiagen PCR Purification kit. Sequence analysis was performed with both PCR primers at Qubitbio. Details of variants and PCR primers used for each are listed in Supplementary Table 3.

gnomAD phenotype curation and cohort descriptions. The below described studies with LRK2 pLoF carriers had available phenotype data. For each study, all available records were manually reviewed to identify any reports of health problems, which were categorized into the following classes: lung, liver, kidney, cardiovascular, nervous system, immune and cancer.

The genomic psychiatry cohort project. The genomic psychiatry cohort project is a longitudinal resource with the aim of making population-based data available through the National Institute of Mental Health. The repository contains whole-genome sequencing (WGS) data and detailed clinical and demographic data, particularly focused on schizophrenia and bipolar disorders. A large proportion of participants (88%) have consented for recontact. The screening questionnaire consisted of 32 yes/no questions about mental health issues and 23 yes/no questions covering other medical problems, which were categorized into the following classes: lung, liver, kidney, cardiovascular, nervous system, immune and cancer.

The age of the 25 LRK2 carriers ranged from 19 to 67 years. Two carriers, aged 55 and 60 years, reported having had liver problems and four participants over 60 years reported no liver problems.

The Pakistan risk of myocardial infarction study. The Pakistan risk of myocardial infarction study comprises 10,503 individuals characterized using a phenotype questionnaire with >350 items covering demographic and dietary characteristics and over 80 blood biomarker measurements. The predominant focus of the questionnaire was cardiac function and phenotype. While the participants were specifically asked to report suffering from asthma, no other lung, liver, kidney, nervous system or immune phenotypes were directly assayed and so these were marked as ‘unknown’ for these individuals. The 12 LRK2 LoF carriers in the study did not differ in terms of age, sex and myocardial infarction status when compared to the entire cohort.

The Swedish schizophrenia and bipolar studies. Cases with schizophrenia or bipolar disorder were identified from Swedish national hospitalization registers. Controls were selected at random from population registers. All individuals had whole-exome sequencing data. All available ICD codes from inpatient hospitalizations and outpatient specialist treatment contacts were provided for each patient.

The national FINRISK study. The FINRISK study has been carried out for 40 years since 1972 every 5 years using independent, random and representative population samples from different parts of Finland. For this work, we used sequencing and health register data from FINRISK surveys between 1992 and 2007 (ref. 40).

Full health records including ICD10 codes were reviewed by study coordinators who provided us with yes/no answers for each of our phenotype classes.

The BioMe biobank at the Charles Bronfman Institute for Personalized Medicine at Mount Sinai. The Mount Sinai BioMe Biobank, founded in September 2007, is an ongoing, broadly consented electronic health record (EHR)-linked bio and data repository that enrolls participants nonselectively from the Mount Sinai Medical Center patient population (New York City). BioMe participants represent broad racial, ethnic and socioeconomic diversity with a distinct and population-specific disease burden, characteristic of the communities served by Mount Sinai Hospital. Currently comprising over 47,000 participants, BioMe participants are of African (24%), Hispanic/Latino (35%) and European (32% of whom 40% are Ashkenazi Jewish) and other/mixed ancestry.

BioME is linked to Mount Sinai’s system-wide Epic EHR, which captures a full spectrum of biomedical phenotypes, including clinical outcomes, covariate and exposure data from past, present and future healthcare encounters. The median number of outpatient encounters is 21 per participant, reflecting predominant enrollment of participants with common chronic conditions from primary care facilities. Clinical phenotype data have been meticulously harmonized and validated.

Genome-wide genotype data and whole-exome sequencing data are available for >30,000 participants. In addition, WGS data are available for >11,000 participants. The full EHRs of three BioMe LRK2 pLoF carriers were reviewed by local clinicians and we were provided with detailed summaries.

Estonian Biobank of the Estonian Genome Center, University of Tartu. The Estonian Biobank cohort is composed of volunteers from the general Estonian resident adult population. The current number of participants of close to 165,000 (representing 15% of the Estonian adult population) makes it ideally suited to population-based studies. Participants were recruited throughout Estonia by medical personnel and participants receive a standardized health examination, donate blood and fill out a 16-module questionnaire on health-related topics such as lifestyle, diet and clinical diagnosis. A detailed phenotype summary from a health survey and linked data including ICD10 codes, clinical laboratory values and treatment and medication information is annually updated through linkage with national electronic health databases and registries.

UK Biobank variant detection and curation. The 49,960 exome-sequenced individuals from the UK Biobank were restricted to a subset of 46,062 unrelated individuals of European ancestry. Relatedness was determined using KING kinship coefficient estimates from the genotype relatedness file with a cutoff of 0.0884 to include pairs of individuals with greater than third-degree relatedness. European ancestry was determined by projecting individuals onto the 100 Genomes Project phase 3.9) principal-component analysis (PCA) coordinate space, followed by Aberrant R package2 clustering to retain only those individuals falling within the 100 Genomes Project EUR PC1 and PC2 limits (λ = 4.5). We further removed individuals who self-reported as non-European ethnicity.

We identified all individuals with putative LoF variants detected in the FE analysis pipeline, which used GATK 3.0 for variant calling and filtering. We did not use the SPB pipeline calls due to advertised errors in the Regeneron Genetics Center pipeline at the time we were conducting these analyses. Variants were included if they were annotated as LoF on any transcript expressed in the lung, liver or kidney. As with the gnomAD analysis, variants were filtered out if they were flagged as low confidence by LOFTEE, before manual curation of the remaining variants. The 12 LRK2 LoF carriers in the study did not differ in terms of age, sex and myocardial infarction status when compared to the entire cohort.
These data were also extracted for G2019S risk allele carriers and these individuals were compared to both pLOF carriers and carriers of neither G2019S nor LRRK2 pLOF variants. There was no significant difference in any of the 34 biomarkers between pLOF and G2019S carriers after accounting for multiple testing (Supplementary Table 15). When comparing G2019S carriers to noncarriers we found significant associations with cystatin C and phosphate levels.

Clinical measures of kidney function. ACR was calculated by dividing the urine microalbumin value (field code 30500; mg/l) by the urine creatinine value (field code 30510; μmol/l) multiplied by a factor of 0.000113222. Estimated glomerular filtration rate was calculated using the CKD Epidemiology Collaboration (CKD-EPI) creatinine equation. Normal range values for both ACR and estimated glomerular filtration rate were taken from the National Kidney Foundation website (https://www.kidney.org/kidneydisease). Spriometry measures of lung function. To assess lung function we used Global Lung Initiative 2012 reference equation z scores standardized for age, sex and height for FEV₁, FVC and FEV₁/FVC ratio measured using spriometry. These calculations are available in field codes 20256, 20257 and 20258 and were described previously.

Grouped phenotype analysis. The list of all codings within the field ‘20002 Non-cancer illness code, self-reported’ were taken from the UK Biobank showcase (http://biobank.ctsu.ox.ac.uk/crystal/coding.cgi?id=6). All selectable codings were given a primary grouping pertaining to the main system relating to that disease. In rare cases where more than one grouping could be assigned, the second was included as a secondary grouping. Diseases with an autoimmune basis were given a secondary grouping to reflect a similar underlying mechanism. Due to the opposing effects of some respiratory diseases, where appropriate, phenotypes in this category were given a secondary grouping of airway, interstitial or pleural. Any codings reflecting symptoms, trauma/injury, benign cancer, mental health phenotypes or disorders were categorized as a result of infection were excluded, as were all gene phenotypes and assigned groupings are listed in Supplementary Table 10. Any coding within the field ‘20001 Cancer code, self-reported’ was assigned a grouping of ‘cancer’. To test for an association between any phenotype group and LRRK2 pLOF carrier status, each individual was counted once as either having self-reported any of the phenotypes within a group or having reported none. A Fisher’s exact test was used to test for an association.

Analysis of ICD10 codes. All ICD10 codes relating to diseases of the liver (K70–K77), diseases of the respiratory system (J00–J99), diseases of the skin (L00–L99), diseases of the circulatory system (I00–I99), other conditions affecting the alimentary tract (J20–J22, J40–J47, J80–J89) or kidney diseases (N00–N92) were curated to exclude any with a primary infectious or external cause (Supplementary Table 12). Asthma was excluded from all analyses to avoid any issues caused by the deliberate ascertainment of the exome-sequence portion of the cohort on the basis of asthma status. For each individual, we extracted all ICD10 codes from the fields ‘41270 Diagnoses: ICD10’ (recorded from episodes in hospital), ‘40001 Underlying (primary) cause of death: ICD10’ and ‘40002 Contributory (secondary) causes of death: ICD10’. The number of carriers and noncarriers with any ICD10 code relating to lung (5 pLOF carriers: 2,378 noncarriers), liver (0 pLOF carriers: 652 noncarriers) or kidney disease (3 pLOF carriers: 2,272 noncarriers) were counted. For J43 (emphysema), J44 (other chronic obstructive pulmonary disease) and J47 (bronchiestasis), ICD10 codes were not counted if they were reported alongside exposure to or history of tobacco use (Z77.22, P96.81, Z87.891, Z57.31, F17 or Z27.20).

23andMe variant annotation and curation. 23andMe participants have been genotyped on a variety of platforms and imputed against a reference panel comprising 56.5 million variants from the 1000 Genomes Project phase 3 (refs. 14 and UK10K). Putative LRRK2 pLOF variants were defined as those classified as high confidence by LOFTEE. Variants were manually assessed for call rate, genotyping and imputation quality and manually curated to ensure they were expected to cause true LOF.

For each of the two genotyped LRRK2 pLOF, we determined carrier status by manually inspecting and custom calling the probe intensity plots. For the imputed variants, carrier status was determined from the mimac-imputed dosage. As these calling methods might produce false positives, we confirmed the participants’ genotypes through Sanger sequencing. Individuals with discordant genotypes were excluded. This resulted in a cohort of 749 individuals, each of whom is a Sanger sequence-confirmed carrier for one of three pLOF variants (Supplementary Table 4).

During initial selection and sequencing, expansion of the database led to inclusion of a number of additional individuals genotyped for one of the pLOF variants GL183902574. We performed custom calling on these individuals and found 354 deemed as high-confidence carriers (Supplementary Table 4). As these individuals were not Sanger sequenced, all subsequent analyses were performed both including and excluding these individuals.

Participants provided informed consent and participated in the research online, under a protocol approved by the institutional review board. Ethical & Independent Review Services, an organization accredited by the Association for the Accreditation of Human Research Protection Programs.

Testing the power to detect an age effect in 23andMe. As a positive control for age analysis, we tested the apolipoprotein E (APOE) Alzheimer’s disease risk allele rs429358, which has a known effect on lifespan. This effect is highly significant in this dataset (P = 1.2 × 10−10). Given that the carrier count for rs429358 is much higher than for LRRK2 pLOF, we compared the power of the 23andMe dataset to detect an age effect associated with LRRK2 pLOF variants that is of the same effect size as the known effect of the APOE allele rs429358 by sampling carriers of this variant. We randomly selected N carriers of rs429358 from the 23andMe dataset, performed a Kolmogorov–Smirnov test on the age distribution of those carriers versus 4,000,000 noncarriers and considered the resulting P value. We repeated this process 100 times and then computed the proportion of these simulations with P < 0.05. This tells us our power to reject the null hypothesis that APOE does not have an effect on age at α = 0.05, if we had N carriers in the dataset. We repeated this for different values of N between 1,000 and 20,000 (Supplementary Table 6). Association testing in the 23andMe dataset. Phenotype selection. The 23andMe dataset includes self-reported phenotype data for thousands of phenotypes across a diverse range of categories. These phenotypes have different sample sizes and prevalence, so the power to detect associations varies widely. We began with a curated set of 748 disease phenotypes. We then applied a liberal filter based on our power to detect an association. More specifically, assuming a minor allele frequency of 2 × 10−5, we restricted to phenotypes where we had power 0.1 to detect an association effect with odds ratio (OR) > 1.3 (for binary traits) or β > 0.2 (for quantitative traits) at α = 0.0001 significance. This left us with 460 binary and 14 quantitative phenotypes.

Association testing. For the subset of 366 health-related phenotypes (excluding any related to diet, drug use, lifestyle and personality), we first restricted testing to individuals for whom we had phenotypic data. We calculated pairwise identity by descent (IBD) over all individuals using a modified version of the IBD64 program and then iteratively removed individuals until we were left with a set of participants, no two of whom shared >700 C/M in IBD. We then tested the association between phenotype and carrier status, controlling for age, sex, genotyping platform and the first ten genetic principle components. We used logistic regression for binary phenotypes and linear regression for quantitative phenotypes.

To control for population structure we restricted our analyses to participants with >97% European ancestry, but the results did not qualitatively change when we dropped this restriction. We also tested associations using only individuals whose carrier status was confirmed by Sanger sequencing, but this also did not result in any meaningful difference. A Bonferroni-corrected P value threshold for 366 independent tests of 1.37 × 10−4 was used to assess statistical significance.

Power analysis. For each phenotype, we computed the theoretical OR we were powered to detect (given in Supplementary Tables 5 and 8) as follows: let m be the proportion of individuals used in the association study of that phenotype who carry the minor allele of the pLOF variant, and let n0 and n1 be the number of controls and cases, respectively. For each OR in the interval (1, 10) at steps of 0.02, we computed the power of the Cochran–Armitage trend test to detect an association between a variant with minor allele frequency m and OR at α = 0.05, with n0 controls and n1 cases. We reported the smallest OR such that the power was ≥0.8.

Analysis of LRRK2 protein levels. Cell culture. All cell lines tested negative for Mycoplasma contamination on a monthly basis with the MycoAlert Detection kit (Lonza, LT07-118) and MycoAlert Assay Control Set (Lonza, LT07-518). Cells were grown at 37 °C with 5% CO2. Cell culture.

All cell lines tested negative for Mycoplasma contamination on a monthly basis with the MycoAlert Detection kit (Lonza, LT07-118) and MycoAlert Assay Control Set (Lonza, LT07-518). Cells were grown at 37 °C with 5% CO2. All cell lines tested negative for Mycoplasma contamination on a monthly basis with the MycoAlert Detection kit (Lonza, LT07-118) and MycoAlert Assay Control Set (Lonza, LT07-518). Cells were grown at 37 °C with 5% CO2.

Broad Institute Office of Research Subject Protection protocol 3639. Cell lines were obtained from Coriell Biorepository (GM18500, GM18501, GM18502, HG01345, HG01346) and approved by the Human embryonic stem cell culture. All pluripotent stem cells were approved by Harvard ESCRO protocol E00052 and E00067. Human ESCs (hESCs) were obtained from WiCell Research Institute (WA01, H1) under a material transfer agreement. Cell lines were authenticated by visual inspection of cell morphology with bright-field microscopy, staining with anti-Oct4 antibody to determine maintenance of pluripotency (Santa Cruz, sc-5279, data not shown), sent to WiCell Research Institute after 6 months of passage and after isogenic cell line generation for karyotyping and in some cases PCA of RNA-seq data to confirm clustering with other pluripotent stem cell lines. Pluripotent stem cells were plated onto hESC-qualified Matrigel (VWR, BD354770)–coated six-well plates, mTeSR1 medium was changed daily (StemCell Technologies, 85850) and cells were passaged every 5–7 days with 0.5 mM EDTA. Lymphoblastoid cell culture. LCLs were obtained from Coriell Biorepository (GM18500, GM18501, GM18502, HG01345, HG01346) and approved by the Broad Institute Office of Research Subject Protection protocol 3639. Cell lines were authenticated by visual inspection of cell morphology with bright-field microscopy.
Cardiomyocyte differentiation. Cardiomyocyte differentiation of the control and engineered H1 hESCs lines was performed according to the protocol by Lian et al. briefly. 500,000 cells were plated on hESC-qualified Matrigel (VWR, BD354277), grown in mTeSR1 medium for 4 d (StemCell Technologies, 85850) and switched to RPMI medium (Life Technologies) with B27 supplement (Life Technologies), switching to B27 with insulin at day 7 for the remainder of the protocol. On day 0 of differentiation, 12 µM CHIR99021 (Tocris) was applied for 24 h. At day 3, cultures were treated with 5 µM IWP2 (Tocris) for 24 h. Bright-field images and movies were acquired at day 17 and cells were collected for protein/RNA extraction at day 19.

Isogenic cell line engineering. The following guide and homologous recombination (HR) template were delivered into single cell H1 hESCs via nucleofection (Lonza). Naito, Y., Hino, K., Bono, H. & Ui-Tei, K. CRISPRdirect: software for designing CRISPR/Cas guide RNA with reduced off-target sites. Bioinformatics 37, 1120–1123 (2015).

Off-target analysis of CRISPR/Cas9 engineering. To detect any potential off-target effects caused by CRISPR/Cas9 genome editing, WGS was conducted for both engineered and control cell lines. DNA extraction, quality control and 30x PCR-free WGS were performed by the Genomics Platform at the Broad Institute. An AllPrep DNA/RNA extraction kit was used, following its protocol. Alignment, marking of duplicated regions, recalibration of quality scores and variant calling were all performed using GATK best practices.

Western blot analysis. Cell pellets were snap-frozen in liquid nitrogen and stored at −80°C. Cells were Dounce-homogenized in ice-cold radiomunoprecipitation assay buffer (89901; Thermo Fisher Scientific) containing protease inhibitors (Halt Protease Inhibitor, Thermo Fisher Scientific). Homogenates were rotated at 4°C for 30 min, followed by centrifugation at 15,000 g for 20 min at 4°C. Equal amounts of protein (50 µg) were electrophoresed on 4–20% SDS–PAGE (Bio-Rad) and transferred to nitrocellulose membranes. The following antibodies were used for immunoblotting: LRRK2 (75–253, UC Davis/National Institutes of Health NeuroMab Facility), anti-actinin (A7811, Sigma), GAPDH (sc-25778, Santa Cruz), anti-rabbit IgG HRP (7074, Cell Signaling) and anti-mouse IgG HRP (7076, Cell Signaling). ImmunobLOTS were developed using enhanced chemiluminescence (SuperSignal West Pico Chemiluminescent Substrate, Thermo Fisher Scientific) on an Amersham Imager 600.

L.F. was supported by the Swiss National Science Foundation (Advanced Postdoc Mobility 177853). T.E. is supported by Estonian Research Council grant PUT1660. L.M. is supported by Estonian Research Council grant PRG184. This research has been conducted using the UK Biobank Resource (https://doi.org/10.1101/572347) under Application Number 42890.

Author contributions D.G.M. and P.C. conceived the study. N.W., I.M.A. and A.K. designed and conducted the main analyses and interpreted the results. J.L.M. conducted the laboratory experiments. E.V.M., J.K.G., N.M.Q., J.B.C., Q.W., K.J.K., B.B.C., L.F. and K.L. contributed to the

Data availability The gnomAD 2.1.1 dataset is available for download at http://gnomad.broadinstitute.org, where we have developed a browser for the dataset and provide files with detailed frequency and annotation information for each variant. There are no restrictions on the aggregate data released. The UK biobank resource was accessed under application number 42890.

Code availability The code used to make the figures is available at https://github.com/macarthur-lab/gnomad_lrrk2.

and in some cases PCA of RNA-seq data to confirm clustering with GTEx LCLs. LCL medium was changed every other day with RPMI 1640 medium (Life Technologies), 2 mM L-glutamine (Life Technologies) and 15% FBS (Sigma).
analysis. A.G., B.A., P.M., M.A.S.B., K.M.M., J.S.W., A.S.H., B.I., J.-J.L., G.N.N., C.W., M.D., T.E., C.H., R.J.F.L., L.M., A.P., C.P., M.P., D.S. and P.F.S. contributed data and/or analysis advice to the study. N.W., J.A., P.C. and D.G.M. wrote the manuscript, with contributions and review by all other authors.

Competing interests
A.K., B.A., A.G., P.M., P.C. and members of the 23andMe Research Team are current or former employees of 23andMe, Inc. and hold stock or stock options in 23andMe. D.G.M. is a founder with equity in Goldfinch Bio and has received research support from AbbVie, Astellas, Biogen, BioMarin, Eisai, Merck, Pfizer and Sanofi-Genzyme. E.V.M. has received research support in the form of charitable contributions from Charles River Laboratories and Ionis Pharmaceuticals and has consulted for Deerfield Management. K.J.K. owns stock in Personalis. M.J.D. is a founder of Maze Therapeutics.

Extended Data Fig. 1 | Ethnicity distribution of LRRK2 LoF carriers in the 23andMe cohort. Bars are coloured according to the detected variant. AFR, African/African American; AMR, American/Latino; NFE, non-Finnish European; SAS, South Asian.
Extended Data Fig. 2 | Details of CRISPR/Cas9-engineered embryonic stem cells and cardiomyocyte differentiation. a, Sanger sequence of isogenic hESC engineered colony for heterozygous LRRK2 variant 10, clone 13 (GRCh37:12-40744897-C-T). The engineered cell line maintains b, a normal karyotype, c, normal colony morphology and expression of OCT4, and d, differentiates into the cardiomyocyte lineage. The bright field image of cardiomyocytes was captured at day 17 of the differentiation protocol. The cardiomyocyte differentiation was repeated 12 times and the staining for Oct4 was repeated on 30 independent colonies.
Extended Data Fig. 3 | IGV visualization of the splice donor variant GRCh37:12-40626187-T-C in the GTEx LRRK2 pLoF carrier exome sequencing data and lung tissue RNA-seq data compared to a control GTEx lung RNA-seq sample. The pLoF variant is observed on reads containing an anchoring missense variant, GRCh37:12-40626185-A-G (A green and G orange), and these reads are presenting normal splicing as seen in the control RNA-seq sample.
Extended Data Fig. 4 | Sex distribution of LRRK2 pLoF carriers, G2019S risk allele carriers and non-carriers in the UK Biobank. Males are shown in dark grey and females in light grey.
Extended Data Fig. 5 | Age distribution of LRRK2 pLoF carriers, G2019S risk allele carriers and non-carriers in the UK Biobank. Data are shown as overlapping density plots.
Reporting Summary

Nature Research wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Research policies, see Authors & Referees and the Editorial Policy Checklist.

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

☐ The exact sample size (n) for each experimental group/condition, given as a discrete number and unit of measurement
☐ A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly
☐ The statistical test(s) used AND whether they are one- or two-sided
☐ Only common tests should be described solely by name; describe more complex techniques in the Methods section.
☐ A description of all covariates tested
☐ A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons
☐ A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals)
☐ For null hypothesis testing, the test statistic (e.g. F, t, r) with confidence intervals, effect sizes, degrees of freedom and P value noted
☐ Give P values as exact values whenever suitable.
☐ For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings
☐ For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes
☐ Estimates of effect sizes (e.g. Cohen's d, Pearson’s r), indicating how they were calculated

Our web collection on statistics for biologists contains articles on many of the points above.

Software and code

Policy information about availability of computer code

Data collection: No software was used to collect the data used in this study.

Data analysis: Custom code was used to analyse data and create the figures in this study. This code has been shared in a GitHub repository. The Genome Analysis ToolKit (GATK) was used to analyse sequencing data generated from CRISPR edited cell lines, according to best practice guidelines. Pybedtools and CRISPRdirect software were used to detect potential off-target edits. The Integrative genome viewer (IGV) and Alamut software were used to curate variants.

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors/reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Research guidelines for submitting code & software for further information.

Data

Policy information about availability of data

All manuscripts must include a data availability statement. This statement should provide the following information, where applicable:
- Accession codes, unique identifiers, or web links for publicly available datasets
- A list of figures that have associated raw data
- A description of any restrictions on data availability

The data presented in this manuscript and the code used to make the figures are available in https://github.com/macarthur-lab/gnomad_lrrk2.
Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

- ☑ Life sciences
- ☐ Behavioural & social sciences
- ☐ Ecological, evolutionary & environmental sciences

For a reference copy of the document with all sections, see nature.com/documents/nr-reporting-summary-flat.pdf

Life sciences study design

All studies must disclose on these points even when the disclosure is negative.

**Sample size**

This study was opportunistic, and involved secondary use of all available data. No sample size was predetermined. We have included the theoretical odds ratios that our sample size is powered to detect for our pheWAS study with the 23andMe data, and a power analysis for our age distribution analysis to demonstrate the size of effect that our sample size can discover.

**Data exclusions**

Identified loss-of-function variant carriers were extensively curated and variants excluded if they were flagged as low-confidence by the Loss-of-Function Transcript Effect Estimator (LOFTEE), or failed a manual inspection of variant quality metrics, read distribution and the presence of nearby variants that could rescue the loss-of-function effect. An additional variant was removed as it was shown to not fully disrupt splicing in the GTEx dataset. Variants from 23andMe were excluded if there were fewer than 5 Sanger validated carriers. Finally, one sample was removed from the UK Biobank that was a carrier of both a LRRK2 pLoF variant and the G2019S risk allele.

**Replication**

We did not attempt to reproduce any findings in a separate dataset, instead all available data was used for discovery analyses.

**Randomization**

As this was a population-based study, no randomization was performed.

**Blinding**

Blinding was not relevant for this population-based study.

Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here, indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.

**Materials & experimental systems**

| n/a | Involved in the study |
|-----|-----------------------|
| ☑ | Antibodies |
| ☑ | Eukaryotic cell lines |
| ☑ | Palaeontology |
| ☑ | Animals and other organisms |
| ☑ | Human research participants |
| ☑ | Clinical data |

**Methods**

| n/a | Involved in the study |
|-----|-----------------------|
| ☑ | ChIP-seq |
| ☑ | Flow cytometry |
| ☑ | MRI-based neuroimaging |

**Antibodies**

The following antibodies were used for immunoblotting: LRRK2 (1:500, 75-253, UC Davis/NIH NeuroMab Facility, lot# 455.71D.04, clone N241A/34), α-actinin (1:5000, A7811, Sigma, Batch# 024M4758, monoclonal EA-53), GAPDH (1:10,000, sc-25778, Santa Cruz, FL-335), anti-rabbit IgG HRP (1:5000, 7074, Cell Signaling), and anti-mouse IgG HRP (1:5000, 7076, Cell Signaling).

**Validation**

These antibodies were selected based on their use in other publications and validation through IF and WB by the companies providing the antibodies. Company provided information is as follows:

LRRK2: Immunogen: Fusion protein amino acids 970-2527 (C-terminus) of human LRRK2 (also known as Leucine-rich repeat serine/threonine-protein kinase 2, Dardarin and PARK8, accession number Q5S007) Mouse: 89% identity (1393/1557 amino acids identical) Rat: 89% identity (1392/1557 amino acids identical) <30% identity with LRRK1 Epitope mapped to within amino acids 1836-1845 (EGDLLVNPDQ) by PEPperPRINT through work funded by The Michael J. Fox Foundation for Parkinson’s Research. Monoclonal antibody info: Mouse strain: Balb/C Myeloma cell: SP2/0 Mouse Ig Isotype: IgG2a NeuroMab Applications: Immunoblot, Immunocytochemistry, Immunohistochemistry and Immunoprecipitation Species Reactivity: human, rat, mouse MW: > 200 kDa Immunoblot versus crude membranes from adult rat brain (RBm) and wild-type (WT) and LRRK2 KO mouse brains probed with N241A/34 (left) and K89/41 (right) TC supe. Mouse brain samples provided by Xiaojie Li, Ted Dawson and Valina Dawson (Johns Hopkins University). Adult rat brain immunohistochemistry (with antigen retrieval via sodium citrate pretreatment).

α-actinin: from product sheet, antibody validated for Immunoblotting (chemiluminescent) in rat leg muscle at 1:5000, 100kDa
GAPDH: GAPDH (FL-335) is recommended for detection of GAPDH and GAPDH-2 of mouse, rat, and human origin by Western Blotting (starting dilution 1:200, dilution range 1:100-1:1000), immunoprecipitation [1-2 μg per 100-500 μg of total protein (1 ml of cell lysate)], immunofluorescence (starting dilution 1:50, dilution range 1:1000-1:500) and immunohistochemistry (including paraffin-embedded sections) (starting dilution 1:50, dilution range 1:50-1:500). Molecular Weight of GAPDH: 37 kDa. Positive Controls: 293T Lysate: sc-159909, Hep G2 cell lysate: sc-2227 or KNRK whole cell lysate: sc-2214.

anti-rabbit IgG HRP: Product Description - Designed for use with rabbit polyclonal and monoclonal antibodies, this affinity purified goat anti-rabbit IgG (heavy and light chain) antibody is conjugated to horseradish peroxidase(HRP) for chemiluminescent detection. This product is thoroughly validated with CST primary antibodies and will work optimally with the CST western immunoblotting protocol, ensuring accurate and reproducible results.

Product Usage Information - Recommended Antibody Dilutions:
1:1000–1:3000
20X LumiGLO® Reagent and 20X Peroxide #7003 1:1K–1:3K
SignalFire™ ECL Reagent #6883 1:1K–1:3K
SignalFire™ Plus ECL Reagent #12630 1:5K–1:15K
SignalFire™ Elite ECL Reagent #12757 1:10K–1:20K

anti-mouse IgG HRP: Product Description - Designed for use with mouse monoclonal and polyclonal antibodies, this affinity purified horse anti-mouse IgG (heavy and light chain) antibody is conjugated to horseradish peroxidase(HRP) for chemiluminescent detection. This product is thoroughly validated with CST primary antibodies and will work optimally with the CST western immunoblotting protocol, ensuring accurate and reproducible results.

Product Usage Information - Recommended Antibody Dilutions:
1:1000–1:3000
20X LumiGLO® Reagent and 20X Peroxide #7003 1:1K–1:3K
SignalFire™ ECL Reagent #6883 1:1K–1:3K
SignalFire™ Plus ECL Reagent #12630 1:5K–1:15K
SignalFire™ Elite ECL Reagent #12757 1:10K–1:20K

Eukaryotic cell lines
Policy information about cell lines

Cell line source(s)
Human embryonic stem cells (hESCs) were obtained from WiCell Research Institute (WA01, H1) under an MTA. Lymphoblastoid cell lines (LCLs) were obtained from Coriell Biorepository (GM18500, GM18501, GM18502, HG01345, HG01346) and approved by the Broad Institute Office of Research Subject Protection protocol #3639.

Authentication
Cell lines were authenticated by visual inspection of cell morphology with brightfield microscopy, staining with anti-Oct4 antibody to determine maintenance of pluripotency (Santa Cruz, sc-5279, data not shown), sent to WiCell Research Institute after 6 months of passaging or after isogenic cell line generation for karyotyping, and in some cases PCA of RNA sequencing data to confirm clustering with other pluripotent stem cell lines or lymphoblastoid cell lines, as appropriate.

Mycoplasma contamination
All cell lines tested negative for mycoplasma contamination on a monthly basis with the MycoAlertTM Detection kit (Lonza, LT07-118) and MycoAlertTM Assay Control Set (Lonza, LT07-518). Cells were grown at 37°C with 5% CO2.

Commonly misidentified lines (See ICLAC register)
No commonly misidentified cell lines were used.

Human research participants
Policy information about studies involving human research participants

Population characteristics
As an opportunistic collection of data, the participants in this study were not selected based on age, gender, or genotypic information. Individuals in the gnomAD dataset have an average age of 53.6 years and 45.8% are female. Individuals were mainly recruited from complex disease studies. Any individuals with severe pediatric disease were removed. In the UK Biobank, individuals have an average age of 56.8 years and 54.4% are female. 23andMe individuals have an average age of 48.8 years and 54.5% are female.

Recruitment
Participants were either customers of the personal genetics company 23andMe, Inc., who consented to participate in research and answer survey questions online, were consented participants of the UK Biobank, or were aggregated as part of the genome aggregation database (gnomAD). Individuals from 23andMe were identified based on their genotyping results and as such were not specifically recruited. Therefore they share the same selection biases such as under representation of certain ethnic and socioeconomic groups relative to the general population. This limits our ability to make any firm conclusions in those groups. Similar biases exist within the gnomAD and UK Biobank datasets which represents secondary use of available sequencing.

Ethics oversight
23andMe - Participants provided informed consent and participated in the research online, under a protocol approved by the external AHRPP-accredited IRB, Ethical & Independent Review Services (E&I Review)
gnomAD - We have complied with all relevant ethical regulations. This study was overseen by the Broad Institute’s Office of Research Subject Protection and the Partners Human Research Committee. Informed consent was obtained from all participants.UKBB - This work was done as part of approved UKBB project #42890

Note that full information on the approval of the study protocol must also be provided in the manuscript.
