Pseudospin 3/2 Fermions, Type-II Weyl Semimetals and Critical Weyl Semimetals in Tricolor Cubic Lattice

Motohiko Ezawa
Department of Applied Physics, University of Tokyo, Hongo 7-3-1, 113-8656, Japan

Multi-band touchings such as 3-band, 6-band and 8-band touchings together with the emergence of high pseudospin fermions were predicted recently at high-symmetry points in three-dimensional space. In this paper, we propose a simple cubic model whose unit cell contains three atoms. There are 6 bands in the system due to the spin degrees of freedom. The 4-band and 2-band touchings are realized at high-symmetry points, where we derive low-energy theories, demonstrating the emergence of pseudospin-3/2 fermions and Weyl fermions, respectively. Away from the high-symmetry points, we find critical Weyl fermions present exactly at the boundary between the type-I and type-II Weyl fermions. This critical Weyl fermion transforms into the type-I or type-II Weyl fermion once the magnetic field is applied.

Dirac, Weyl and Majorana fermions have attracted much attention in condensed matter physics in views of topology and symmetry. They have a 2-band touching with a linear dispersion. Dirac and Weyl fermions emerge in various materials, which are called Dirac and Weyl semimetals [1]. An interesting feature of Weyl semimetals is that they have a monopole charge in the momentum space, which protects the existence of the Weyl points topologically [2]. The type-II Weyl semimetal has attracted much attention recently [3–12], which emerges when the Weyl cone is highly tilted so that the Fermi surface consists of a pair of electron- and hole- pockets touching at the Weyl point. It is experimentally realized in MoTe$_2$ [13,14], LaAlGe$_3$ [15], WTe$_2$ [16,17], TaIrTe$_4$ [18,19], PtTe$_2$ [20] and Ta$_3$S$_2$ [21].

Very recently, new types of fermions with multi-band touching were proposed based on the symmetry analysis as well as the first-principles calculations, where 3-band [22,23], 6-band [24,25] and 8-band touchings were reported at high-symmetry points. Especially, it is shown that the 3-band touchings are well described by the fermions carrying the pseudospin $1$. Furthermore, the 8-band touching has been proposed in antiperovskites to produce a pseudospin-3/2 fermion [29]. On the other hand, the 4-band touching is yet to be realized although some discussions were given in the supplement of Ref. [29].

In this paper, motivated by these proposals on multi-band touchings and fermions carrying higher pseudospins, we present tight-binding models possessing 4-band and 2-band touchings [Fig.1]. They are realized naturally in a lattice structure with the cubic symmetry where the unit cell contains three atoms [Fig.2]. We call it a tricolor cubic lattice. First, we derive the low-energy 4-band theory at the high-symmetry points, which is shown to produce pseudospin-3/2 fermions having the angular momenta $j = (-3/2,-1/2,1/2,3/2)$. We also show that the bands have monopole charges $-3, -1, 1, 3$ at these points. Second, the 2-band theory is described by the Weyl fermion. Furthermore, away from the high-symmetry points, we find a critical Weyl fermion, which resides at the exact boundary of the type-I and type-II Weyl fermions. They transform into the type-I or type-II Weyl fermions once the magnetic field is applied.

Tricolor cubic lattice: We consider a cubic lattice as illustrated in Fig.2(a). Though it looks complicated, the unit cell is quite simple. It contains three atoms represented by magenta, cyan and yellow spheres [Fig.2(b)]. Each color atom forms the body-center cubic lattice. We call it a tricolor cubic lattice. The Brillouin zone is shown in Fig.2(c). There are four high-symmetry points: $\Gamma (0,0,0)$, $P (\pi,\pi,\pi)$, $N (\pi,\pi,0)$ and $H (2\pi,0,0)$. Additionally, there are important points named $\Delta (\pi,0,0)$, $G (3\pi/2,\pi/2,0)$, $\Sigma (\pi/2,\pi/2,0)$, $\Lambda (\pi/2,\pi/2,\pi/2)$, $F (3\pi/2,\pi/2,\pi/2)$, $D (\pi,\pi,\pi/2)$.

Model Hamiltonian: The main term of the lattice Hamiltonian is the hopping term along the bonds $d_{ij} = r_i - r_j$ connecting a pair of the nearest neighbor sites $i$ and $j$ in the tricolor cubic lattice [Fig.2(a)]. We also introduce the spin-orbit interaction (SOI) preserving the cubic crystalline symmetry [29],

$$H_{SO} = i\lambda \sum_{\langle i,j \rangle} c_i^\dagger [\sigma \cdot d_{ij}] c_j,$$

with $\lambda$ the coupling strength and $\sigma = (\sigma_x, \sigma_y, \sigma_z)$ the Pauli matrix for the spin. The Hamiltonian has six bands due to the spin degrees of freedom. The 6-band Hamiltonian reads

![FIG. 1: Bird's eye's view of the band structure near the P point. The horizontal plane is spanned by the $k_x$ and $k_z$ axes. The vertical axis is the energy $E = E(k_z, \pi, \pi_z)$. (a) 2-band (cyan circle) and 4-band (red circle) touchings are observed at the P point. There appears other 2-band touchings (green circle) off the P point. (b)(c) An enlarged portion of the 2-band (4-band) touching indicates the emergence of (one) two Weyl cones at the P point.](image-url)
The Hamiltonian by an unitary transformation $U$, 
\[ U^{-1} H_0 U = \nu t \text{diag}(2, 2, -1, -1, -1, -1), \]
with the high-symmetry points $\Gamma$, $P$, $N$, $H$ and also at the $\Delta$ point.

**Band structure:** The energy spectrum is obtained by diagonalizing the Hamiltonian. We show the band structure along the line $\Gamma - \Delta - H - G - N - \Sigma - \Gamma - \Lambda - P - F - H - F - P - D - N$ in Fig. 3 for typical values of the parameters $t$ and $\lambda$. The 4-band and 2-band touchings are observed at various points in Fig. 3(b). The high-symmetry point $P$ is typical, around which we show the bird’s eye’s view of the band structure in Fig. 4.

The 4-band touchings are protected by the cubic crystalline symmetry and the time-reversal symmetry. They occur at the high-symmetry points $\Gamma$, $P$, $N$, $H$ and additionally at the $\Delta$ point. Hence, hereafter we  count the point $\Delta$ as a member of the high-symmetry points. Let us explain how the 4-band touching emerges. As shown in Fig. 3(a), in the absence of the SOI, the four-fold degeneracy is present due to the cubic crystalline symmetry at the high-symmetry points. Even by including the SOI, the bands never split at the time-reversal invariant momentum points, which implies the Kramers degeneracy. (In the present model this is realized since the SOI is zero at these points.) Consequently, the 4-fold degeneracy without the SOI yields the 4-band touching with the SOI at all the high-symmetry points [Fig. 3(b)].

To explore these touchings analytically we diagonalize the Hamiltonian by an unitary transformation $U$,
\[ U^{-1} H_0 U = \nu t \text{diag}(2, 2, -1, -1, -1, -1), \]
at the high-symmetry points: $\nu = +$ for the $\Gamma$, $N$ and $H$ points and $\nu = -$ for the $P$ and $\Delta$ points. The bands with the first two energies $2\nu t$ form a 2-band touching, while those with the four energies $-\nu t$ form a 4-band touching as in Fig. 3(b).

**4-band touching:** First we construct the 4-band model by way of $H_4(k) = P_3 U^{-1} H_0(k) U P_2$, where $U$ is fixed by $[3]$ while $P_3$ is the projection operator from the $6 \times 6$ Hamiltonian to the $4 \times 4$ Hamiltonian containing the four bands with the eigen energies $-\nu t$. The 4-band Hamiltonian is derived up to the linear order of $k_\alpha$ as
\[ \nu H_4 = -t \begin{pmatrix} 0 & \eta \sqrt{3} k_x & 3 i k_y & \eta \sqrt{3} k_z \\ \eta \sqrt{3} k_x & -2 k_x & \eta \sqrt{3} k_z & 2 k_x - i k_y \\ -3 i k_y & \eta \sqrt{3} k_z & 0 & -\eta \sqrt{3} k_z \\ \eta \sqrt{3} k_z & 2 k_x + i k_y & -\eta \sqrt{3} k_z & 2 k_z \end{pmatrix}, \]
where $\eta = +$ for the $\Gamma$, $P$, $N$, $H$ points and $\eta = -1$ for the $\Delta$ point. Here we have set the origin of the momentum $k_\alpha = 0$ at each high-symmetry point to investigate physics near the point. This Hamiltonian $[4]$ is exactly diagonalizable,
\[ E_j = \nu t \pm \frac{2j}{3} \lambda k, \quad k = |k|, \]
which is independent of $\eta$, where $j = -3/2, -1/2, 1/2, 3/2$. The energy spectrum consists of two Weyl cones with velocities $\lambda/3$ and $\lambda$ [Fig. 3(b)].

**Pseudospin 3/2 fermion:** The energy eigenvalues $[5]$ as well as the eigenfunctions are the same as those of the pseudospin-3/2 Weyl fermion defined by
\[ H_4 = \nu t + \frac{2}{3} \lambda \mathbf{k} \cdot \mathbf{J}, \]
where $\mathbf{J}$ is the pseudospin-3/2 operator. It implies that the Hamiltonian $H_4$ is unitary equivalent to the system of the pseudospin-3/2 fermions.
A comment is in order with respect to the pseudospin-3/2 fermion. It has already been proposed in antiperovskites, where the Hamiltonian is written as \[ H = m \tau_z + v_1 \tau_x k \cdot J + v_2 \tau_y k \cdot \tilde{J}. \] (7)

It is an 8-band model due to the presence of another pseudospin degrees of freedom \( \tau \). Furthermore, this model has another operator \( \tilde{J} \) preserving the cubic symmetry, which introduces another velocity \( v_2 \). In general, it is impossible to obtain the exact energy spectrum of this Hamiltonian.

**Monopoles:** With the use of the eigen function, the Berry curvature is explicitly calculated for each band as

\[ \Omega_j = i \nabla \times \langle \psi_j | \nabla \psi_j \rangle = \frac{k}{\Omega} \] (8)

where \( j \) labels the band with \( j = -3/2, -1/2, 1/2, 3/2 \). In deriving the formula we have used the fact \( \frac{\partial \psi_j}{\partial \Omega} = 0 \). Since

\[ \rho_j = \frac{1}{2\pi} \iiint \nabla \cdot \Omega_j = 2j = -3, -1, 1, 3, \] (9)

the Berry curvature of the band indexed by \( j \) describes a monopole with the monopole charge \( 2j \).

**Weyl semimetals:** We may also construct the 2-band model by way of \( H_2(k) = P_2 U^{-1} H_0(k) U P_2 \), where \( P_2 \) is the projection operator from the \( 6 \times 6 \) Hamiltonian to the \( 2 \times 2 \) Hamiltonian containing the two bands with the eigen energies \( 2\nu \) in \( H \). The low-energy 2-band model derived from this Hamiltonian describes Weyl fermions, \( \nu H_2 = 2t + \frac{2}{3} \lambda (k_x \sigma_x - k_y \sigma_y - k_z \sigma_z). \) (10)

We may verify the presence of monopole doublets \( \pm 1 \) at the points \( \Gamma, N, H \), and \( \mp 1 \) at the points \( P, \Delta \), where the upper (lower) component dictates the monopole charge of the upper (lower) band. It is remarkable that Weyl fermions emerge naturally in the present 3-dimensional tight-binding model. The Weyl semimetal is topologically protected as far as the 2-band touching is intact.

We note that there exist also 2-band touchings at the points \( G \) and \( \Sigma \). However, since the effective theory is derived as

\[ H = \pm (-t + \lambda k_z \sigma_z), \] (11)

they do not describe Weyl semimetals.

**Critical Weyl semimetals:** 2-band touchings emerge also at points which have no conventional names. See points marked by two green circles in Fig.4(a) and Fig.4(a1). We study the band structure near the points. Since they locates on the \( k_z \) axis, we derive the energy spectrum of the Hamiltonian \( H_4 \) by setting \( k_x = k_y = 0 \). It is given up to the order of \( k_z^2 \) as

\[ \nu E(0, 0, k_z) = -t \mp \lambda k_z + \frac{t^2}{2} k_z^2, \] (12)

We can check that these parabolic curves fit the results obtained by the 6 band tight-binding model very well. There are 2-band crossing points at \( k_z = \pm \lambda / t \) with the energy \( \pm (t + \lambda^2 / 2t) \): See Fig.4(a2). In the vicinity of these points, we derive the 2-band model with the use of \( k_z' = k_z \mp \lambda / t \), \( \nu H = -t - \frac{\lambda^2}{2t} \pm \frac{1}{3} \lambda k_z' + \frac{t}{3} k_z'^2 \) \( + \frac{\lambda}{\sqrt{3}} \left(-k_x \sigma_x + k_y \sigma_y + \frac{1}{\sqrt{3}} k_z' \sigma_z \right) \pm \frac{t}{3} k_z'^2 \sigma_z. \) (13)

The energy spectrum along the \( k_z \) axis is given by

\[ \nu E(0, 0, k_z') = -t - \frac{\lambda^2}{2t} + \frac{1}{2} k_z'^2, -t - \frac{\lambda^2}{2t} + \frac{2}{3} \lambda k_z' - \frac{t}{6} k_z'^2. \] (14)
Magnetic-field-induced type-II Weyl semimetals: We apply external magnetic field \(B \neq 0\) in the [001] direction. The Hamiltonian is given by adding the term \(B \sigma_z \otimes I_3\) to the Hamiltonian (2), where \(I_3\) is the \(3 \times 3\) unit matrix. There occurs the Zeeman split in the band structure as in Fig. 4.

With respect to the 2-band touching (Weyl point), the only effect of the magnetic field is adding the Zeeman term \(B \sigma_z\) to the Hamiltonian (2). It results in a shift of the Weyl point in the \(z\) direction, but the gap never opens.

On the other hand, the 4-band touching is broken under the magnetic field. This is because it is protected by the time-reversal symmetry and the cubic symmetry.

Type-II Weyl fermions are produced in two different ways as the magnetic field is introduced. (i) First, as we remarked just in above, there exist critical Weyl points in the vicinity of the 4-band touching point [Fig. 5(a) and Fig. 5(a)]. They are turned into the type-I and type-II Weyl points (b) and Fig. 5(b)]. (ii) Second, as the 4-point touching is broken, there appear six 2-point touchings in general as in Fig. 6(b4), among which we find type-II Weyl points.

We discuss the case (i): See Fig. 5. We study how the critical Weyl fermions are modified under magnetic field. The crossing points are given by \(k_z = \pm (\lambda + \sqrt{\lambda^2 + 12 B I}) / 2t\). In the linear order of \(B\), the additional term to the 2-band model \(\nu H_B\) is

\[
\nu H_B = B \left( \pm \frac{t}{\lambda} k'_z - \frac{2t}{\lambda} k''_z \sigma_z \right).
\]

It transforms the two critical Weyl fermions into the type-I and type-II Weyl fermions.

Next we discuss the case (ii): See Fig. 6(b3). In the 4-band linear model, the energy spectrum along the \(k_z\) axis is given by \(\nu E = t \pm (\lambda k_z - B)\), \(t \pm (\frac{1}{2} \lambda k_z - B)\). There are 2-band crossings at \(k_z = 3B/\lambda\). In the vicinity of this point, the 2-band model is given by

\[
H = \pm [-t + 2B - \frac{2}{3} \lambda k'_z - \frac{\lambda}{\sqrt{3}} (k_z \sigma_x - k_y \sigma_y - \frac{1}{\sqrt{3}} k'_z \sigma_z)]
\]

with the energy spectrum

\[
E = \pm \left( -t + 2B - \frac{2}{3} \lambda k'_z \pm \frac{1}{3} \lambda \sqrt{3 k^2_y + 3 k^2_y + k^2_z} \right).
\]

Since the tilt of the Weyl cone is larger than the velocity of the Weyl cone, they are type-II Weyl points.

We have mentioned the emergence of type-II Weyl points in two different ways. Interestingly they are pair annihilated at \(B = \pm \lambda^2 / 12t\) and disappear for \(|B| > \lambda^2 / 12t\), as shown in Fig. 6(b) and Fig. 6(c), respectively.

The author is very much grateful to N. Nagaosa for many helpful discussions on the subject. He thanks the support by the Grants-in-Aid for Scientific Research from MEXT KAKENHI (Grant Nos. JP25400317 and JP15H05854).
