LINK ALGEBRA: A NEW APPROACH TO GRAPH THEORY

ALFONSO BUSTAMANTE V

Abstract. In this paper we develop a structure called Link Algebra, in which we present a Set with two binary operations and an axiom system developed from the study of graph theory and set/antiset theory, sowing main theorems and definitions. Once introduced Link Algebra, we will show the application on graph theory, like defining Paths, cycles and stars. Finally, we will see an alternative axiomatizations with Multisets and ordered pairs to algebraically define mutli, pseudo and oriented graphs.

1. Introduction

In mathematics, algebraic structures usually represent the axiomatication of known objects, hide in the depths of an unsolved problem. The structure under consideration in this work, was inspired in a problem apparently trivial: if we have a graph defined as the usual like the 2-tuple (Berge [4])

\[ G = (V, E), \]

where \( V \) is the set of vertexes and \( E \) is the set of the unordered pair of vertexes (in a non-oriented graph) of edges, then we assume a graph \( G \) with his subgraph \( G' \), and we want to find the graph \( X \) in the graph \( G \), this is

\[ G = G' \cup X. \]

If we consider only the assumptions on graph theory so far, which is basically based on ZF set theory axiom system, we have no solution to the problem. If we look, instead, at the extension made in the works of Carroll [2](2009) and Gatica [1](2010), considering the existence of an antiset \( B \) where

\[ A \cup B = \emptyset, \]

with \( B = \tilde{A} \) the solution would be

\[ G \cup \tilde{G}' = X, \]

Date: 17 of March, 2011.

During the development of this work, we had the initial support of Jorge Soto Andrade, Luis Arenas, Ricardo Osorio and Daniela Ruiz, which motivated us to move forward. We also received help from Boris Roa, with the idea of graph union and simple link as complete bipartite graph; Natalia Reyes with the proposal of some theorems and corollaries; and Andre Caceres in the correction and translation of the manuscript. Without this help we would not have been able to finish our work.
where naturally emerges the concept of antigraph as a solution for a graph boolean equation system with one variable. This way of working graphs will help to bring simplest solutions to apparently complex problems.

Before we start to define our algebraic structure, we will introduce some prelminar concepts, like graphs, the definition of set union al link, and the basic of set/antiset theory.

2. Introduction to Link Algebra

2.1. Graph Theory. In graph theory, the concepts of vertex and edge are essential: is the source of thousands of objects and forms, but the problem lies in one thing: it is still atached to combinatorial analisis and arithmetic formulations. Is not a propper object with an algebraic background: it is still a mathematical bricolage of external mathematicas sub-areas.

For many years, graphs has been consider as a mere exentricity born in the mind of Euler to solve the Koenigsberg bridge problem; in the XX century, Claude Berge made a more formal definition based on the definition by Konig, giving emphasis in the vertex and edges.In this new century, the view of graph has lightly changed: they still remains as 2-tuples only used when the ocation appears; but if we take a closer look of some basic concepts in their theory, we will be able to see the strucure that lies beneath the surface.

In order to make a better background, lets remind the following concepts: complete bipartite graph, null graph and graph union.

A complete bipartite graph is ussually defined as

\[ K_{n,m} := (V_1 \cup V_2, E) \]

where E is the set of the pairs formed by the conection of the edges v in \( V_1 \) and w in \( V_2 \), with n and m the number of vertex contained in the set \( V_1 \) and \( V_2 \) respectively.

The next concept is the null graph, which is defined as

\[ N_n := (V, \emptyset) \]

having vertexes but no edges, where n is the number of edges.

Finally, we have graph union which is definded as

\[ G := (V \cup V', E \cup E') \]

where V and V' are the vertexes of two diferent graphs, being E and E' their edges. With this three concepts, we are now able to construct the main operations of Link Algebra.

2.2. Basic Definitions. From the concepts view of graph theory, we can construct the main definitios of our work.

**Definition 2.1.** We define the union between two graphs G and G' as

\[ G \sqcup G' := (V \cup V', E \cup E') \]
**Definition 2.2.** We define the linking between two graphs $G$ and $G'$ as

1. $N_n \Lambda N'_m := K_{n,m}$, if they are null graphs;
2. $G \Lambda G' := G \mathrel{\Lambda} G' \mathrel{\Lambda} K_{n,m}$, where $N_n$ and $N'_m$ are the null graphs of $G$ and $G'$ respectively.

Once defined this operations, we will construct the fundamental objects of graph theory: Vertexes and Edges, objects that will allow us to create the laws that will support our algebraic structure.

Back in the definition of null graph, it is not to difficult to define a single vertex, we only need $n=1$ and the definition is done. In the other case, the edge, we will need the definition of connection between two null graphs of one vertex. Hence, the concepts could be defined as follows:

**Definition 2.3.** We define a Vertex $v$ from the single graph $G$ as

$$v_G := N_1,$$

where $N_1$ is the null graph of the single graph $G$.

**Definition 2.4.** We define a Edge $e$ from the edge graph $G$ as

$$e_G := N_1 \Lambda N'_1,$$

where $N_1$ and $N'_1$ are the null graphs of the single subgraph $H$ and $H'$ of $G$ respectively.

Before we start defining a Connective Algebra an its laws, lets make a little introduction to set/antiset theory, for prepare the ground to the proper concept of antivertex and antiedge.

### 3. A step back in to the land of sets

#### 3.1. Sets and Antisets.

When Zermelo and Fraenkel made the axioms of set theory, they consider sets as an unique unit in the set universe. After the appearance of the antiparticle in physics, many mathematicians started to search a possible analogy in the land of sets. The problem was that the axiomatization made was unable to accept such antielements or antisets. In the 90’s some mathematicians started to ask if there was a possibility to make an extension to accept such idea. Then in this century, works like those from Caroll or Gatica made de proper needed axiomatization. In this brief section, we will introduce the basis of set/antiset theory for using in graph theory to define antigraph, taking the notation from the work of Carroll.

As we defined before, let be $A$ and $B$ sets which

$$A \cup B = \emptyset,$$

where $B = \tilde{A}$, defined as antiset of the set $A$.

---

1. If the reader is interested, use as an example $G = (\{a, b\}, \{ \{a, b\}\})$ and $G' = (\{c, d\}, \{ \{c, d\}\})$. 
In both works, they start by defining union in to a element view, so, union, in this form is defined for a set \( A \) and \( B \) which
\[
A \cup B := \bigcup \{A, B\},
\]
where \( A \) could be \( A = \{a\} \) and \( B = \{b\} \) where naturally
\[
A \cup B = \{a\} \cup \{b\} = \{a, b\},
\]
which is also called axiom of fusion. If \( A \) and \( B \) are sets of subsets, the subsets interact as they were just elements, this is, there are no fusion inside fusions. Is also important to mention that is linear and the sign of the set also keeps in their elements, this is
\[
\begin{align*}
(a) \quad \hat{A} \cup \hat{B} &= \hat{A} \cup \hat{B} \\
(b) \quad \hat{A} &= \{\hat{a}\},
\end{align*}
\]
in Carroll’s work [2], this is clearly defined, and derived naturally from the ZF axiomatic extension of the fusion and the union of elements.

with this, it is posible to define the Boolean Algebra with an extention of antielements. For that reason, the new universe set will be defined as a set with both positive and negative properties. The boolean algebraic properties remains as ussually for the operations union and intersection, now extended to antisets.

3.2. **Consecuences in Graph theory.** Using this extension in graphs, gives the naturally the concept of antigraph, this is
\[
\hat{G} := (\hat{V}, \hat{E}),
\]
which joined to the graph \( G \) (now extended) it result to be
\[
G \cup \hat{G} := (\{\emptyset\}, \{\emptyset\}),
\]
where \( (\{\emptyset\}, \{\emptyset\}) \) is definied as the empty graph \( \phi_G \).

In the same way, we will define an antivertex and an antiedge as
\[
\begin{align*}
\hat{v}_G &:= \hat{N}_1, \\
\hat{e}_G &:= \hat{N}_1 \hat{A} \hat{N}_1',
\end{align*}
\]
Other important consecuence, is the solution of the equation \( G = G' \cup X \) seen in the introduction as \( X = G \cup \hat{G}' \). Showed this concepts, we are finally able to define our algebraic structure.
4. Link Algebra

4.1. Definition of Link Algebra. In abstract algebra, in general, the algebraic structure represents the true goal beneath the scrutiny of those hide patterns in the behave of a mathematical object. Graphs has been seen as diagrams, even confused with Graphics, missing their true nature in the world of mathematics.

The structure, finally introduced in this section, has developed from the concepts in graph theory redefined by set/antiset theory and the new definition of vertex by using the concept of null graphs.

Definition 4.1. A Link Algebra is a set $G$ (extended to antigraphs) of vertexes $v$ with the operations $\dashv\bowtie$ and $\dot\Lambda$ satisfying the following axioms

1. **Closure**
   
   \[ v \dashv\bowtie w \in G, \quad v\dot\Lambda w \in G. \]

2. **Idempotency**
   
   \[ v \dashv\bowtie v = v, \quad v\dot\Lambda v = v. \]

3. **Associativity**
   
   \[ v \dashv\bowtie (w \dashv\bowtie t) = (v \dashv\bowtie w) \dashv\bowtie t, \quad v\dot\Lambda(w\dot\Lambda t) = (v\dot\Lambda w)\dot\Lambda t. \]

4. **Identity element**
   
   There exist an element $\phi$, that for every element of $G$ the equation
   
   \[ v \dashv\bowtie \phi = v, \quad v\dot\Lambda \phi = v. \]

5. **Inverse element**
   
   For every element $v$ of $G$ there exist an element $\tilde{v}$ in $G$ that
   
   \[ v \dashv\bowtie \tilde{v} = \tilde{v} \dashv\bowtie v = \phi, \quad v\dot\Lambda \tilde{v} = \tilde{v}\dot\Lambda v = \phi. \]

6. **Commutativity**

   \[ v \dashv\bowtie w = w \dashv\bowtie v, \quad v\dot\Lambda w = w\dot\Lambda v. \]

7. **Distributivity**

   (a) $v\dot\Lambda(w \dashv\bowtie t) = (v\dot\Lambda w) \dashv\bowtie (v\dot\Lambda t)$.
   
   (b) $(w \dashv\bowtie t)\dot\Lambda v = (w\dot\Lambda v) \dashv\bowtie (t\dot\Lambda v)$.

---

2Except for $v = w$ and $t = \tilde{v}$, to avoid the same problem in set/antiset theory. If the reader is interested, see Gatica’s work.
Connectivity

For every equation $\Gamma$ and $\Gamma'$ of $G$, where

$\Gamma = V \xrightarrow{\ldots} E$,

being $V$ and $E$ defined as

(a) $V = v_1 \xrightarrow{\ldots} v_p$

(b) $E = w_1 \xrightarrow{\ldots} w_q \xrightarrow{\ldots} t_q$

(c) $N_n = V \xrightarrow{\ldots} w_1 \xrightarrow{\ldots} t_1 \xrightarrow{\ldots} w_q \xrightarrow{\ldots} t_q$

with $N_n$ (where $n = p + 2q$) and $N'_m$ their vertex equations

$\Gamma \Delta \Gamma' := \Gamma \xrightarrow{\ldots} \Gamma' \xrightarrow{\ldots} N_n \Delta N'_m$.

Some of the axioms within the structure, bring the open possibility to construct some important objects in graph theory, such as Paths, Cycles, Stars and complete graphs; but before, we will look at the fundamental properties of the Link Algebra to continue with the construction of main objects such $K$, $P$, $C$ and $S$ equations.

4.2. Theorems of Link Algebra. The following theorems, except few, have proofs using just the basic of group theory. If the reader is interested, could see this proofs in the work of Kaufman and Percigout [3], in the sections of groups.

Theorem 4.2. if $v, w$ and $t \in G$ and $v \dot{\Lambda} t = w \dot{\Lambda} t$, then $v = w$

Proof. One way to solve the equation $v \dot{\Lambda} t = w \dot{\Lambda} t$ is by linking $\tilde{t}$ and using the axiom (8), this is

\[
\begin{align*}
v \dot{\Lambda} t &= = w \dot{\Lambda} t \\
(v \dot{\Lambda} t) \dot{\Lambda} \tilde{t} &= = (w \dot{\Lambda} t) \dot{\Lambda} \tilde{t} \\
v \dot{\Lambda} \tilde{t} \xrightarrow{\ldots} (v \dot{\Lambda} \tilde{t}) \dot{\Lambda} \tilde{t} &= = w \dot{\Lambda} \tilde{t} \xrightarrow{\ldots} (w \dot{\Lambda} \tilde{t}) \dot{\Lambda} \tilde{t} \\
v \dot{\Lambda} \tilde{t} \dot{\Lambda} \phi &= = w \dot{\Lambda} \tilde{t} \dot{\Lambda} \phi \\
v \dot{\Lambda} \tilde{t} \dot{\Lambda} \phi \dot{\Lambda} v &= = w \dot{\Lambda} \tilde{t} \dot{\Lambda} \phi \dot{\Lambda} v \\
v \dot{\Lambda} \tilde{t} v &= = w \dot{\Lambda} \tilde{t} v \\
v \dot{\Lambda} \tilde{t} v &= = w \dot{\Lambda} \tilde{t} v \\
v \dot{\Lambda} \phi &= = w \dot{\Lambda} \phi \end{align*}
\]

The other way, is by using the axiom (3), (5) and (4).

\[\square\]

Theorem 4.3. For every $v \in G$, $v \dot{\Lambda} \phi = \phi \dot{\Lambda} v$

Theorem 4.4. A link Algebra, has a single neutral element.

Proof. Lets suppose that there is a $\phi'$ that $\phi \dot{\Lambda} \phi' = \phi$ and $\phi' \dot{\Lambda} \phi = \phi'$, occurs. Using the axiom (6), the consequence is immediate. The same occurs for $\xrightarrow{\ldots}$.

\[\square\]
Theorem 4.5. For every \( v \) of \( G \), \( \tilde{v} \lambda v = v \lambda \tilde{v} \)

Theorem 4.6. if \( v, w \) and \( t \in \) and \( t \lambda v = t \lambda w \), then \( v = w \)

Theorem 4.7. Every element of a link algebra have a single inverse element.

Theorem 4.8. If \( v \in G \), then \( \tilde{v} = v \)

Proof. We want to know if there is some \( \tilde{v} \) that

\[ \tilde{v} : \vdash \tilde{v} = \phi \]

lets take the axiom (5) for \( \vdash \)

\[ \tilde{v} : \vdash v = \phi, \]

using the theorem \( \text{[4.6]} \) we proof that \( \tilde{v} = v \)

\[ \Box \]

Theorem 4.9. If \( v \) and \( w \in G \), exists single \( x \) and \( y \) of \( G \) that \( v \lambda x = B \) and \( y \lambda v = B \)

Theorem 4.10. \( \langle G, \vdash \rangle \) obey group theorems.

4.3. Objects in Link Algebra. In Link algebra, same as graph theory, there are fundamental objects like Paths, Cycles, Stars and Complete Connective forms. In this section we will present the definition of those objects.

Definition 4.11. \( \forall v_1, \ldots, v_n \in G \), an equation is called Path if

\[ P_n = v_1 \lambda v_2 \vdash \cdots \vdash v_{n-1} \lambda v_n \]

Definition 4.12. \( \forall v_1, \ldots, v_n \in G \), an equation is called Cycle if

\[ C_n = P_n \vdash v_1 \lambda v_n \]

Definition 4.13. \( \forall v_1, \ldots, v_n \) and \( w \in G \), an equation is called Star if

\[ S_n = w \lambda (v_1 \vdash \cdots \vdash v_n) \]

Definition 4.14. \( \forall v_1, \ldots, v_n \in G \), an equation is called Complete Connective Form if

\[ K_n = v_1 \lambda \ldots \lambda v_n. \]

Definition 4.15. \( \forall v \) and \( w \in G \), an Edge is defined as

\[ \bar{e} = v \lambda w. \]

Definition 4.16. \( \forall v_1, \ldots, v_n \in G \), an equation is called Null Form if

\[ N_n = v_1 \vdash \cdots \vdash v_n. \]
4.4. **Aplication on Graph Theory.** As we said in the introduction, we will show how Link Algebra is useful on Graph Theory. Therefore, we will give some main theorems derived from the figures in the earlier section. Some will be demonstrated, the rest are easy to proof from the other theorems.

**Theorem 4.17.** If $V = v_1 \vdash \cdots \vdash v_n$, then $K_n = \Lambda V$.

*Proof.* Using the definition of $K_n$ and using recursively the axiom (8)

$K_n = v_1 \Lambda \cdots \Lambda v_n$

$= v_1 \vdash \cdots \vdash v_n \vdash v_{n-1} \Lambda v_n \vdash \cdots \vdash v_1 \Lambda (v_2 \vdash \cdots \vdash v_n)$

$= v_1 \Lambda v_1 \vdash \cdots \vdash v_n \Lambda v_n \vdash S_1 \vdash \cdots \vdash S_n$

$= v_1 \Lambda v_1 \vdash \cdots \vdash v_n \Lambda v_n \vdash S \vdash S$

$= v_1 \Lambda (v_1 \vdash \cdots \vdash v_n) \vdash \cdots \vdash v_n \Lambda (v_1 \vdash \cdots \vdash v_n)$

$= \Lambda V$

Where $S = S_1 \vdash \cdots \vdash S_n$ And the proof is done. □

**Theorem 4.18.** If $V = v_1 \vdash \cdots \vdash v_n$, then $S_n \vdash V = S_n$

*Proof.* using the definition of star

$S_n \vdash V = w \Lambda (v_1 \vdash \cdots \vdash v_n) \vdash V$ (using the hipotesis)

$= w \Lambda V \vdash V$ (using (4))

$= w \Lambda (V \vdash \phi)$ (using (7))

$= S_n$ (using (4) and the def 4.13)

which is, as a matter of fact, a Star. □

**Theorem 4.19.** $P_n$ is inductive.

*Proof.* Using Peano Axioms, the case $n=1$ is trivial. Now, we need to prove that $P_n$ implies $P_{n+1}$.

$P_{n+1} = v_1 \Lambda v_2 \vdash \cdots \vdash v_{n-1} \Lambda v_n \vdash v_n \Lambda v_{n+1}$ (using def 4.11)

$= P_n \vdash v_n \Lambda v_{n+1}$ (using def 4.11 again)

so, $P_n$ is inductive. □

**Corollary 4.20.** $C_n$ is inductive.

*Proof.* the case $n=1$, as in the theorem, is trivial. We need to prove that $C_n$ implies $C_{n+1}$.

$C_{n+1} = P_{n+1} \vdash v_{n+1} \Lambda v_{n+1}$

$= P_n \vdash v_n \Lambda v_{n+1} \vdash v_1 \Lambda v_{n+1}$

$= P_n \vdash R \vdash v_1 \Lambda v_{n+1} \vdash v_1 \Lambda v_{n}$

$= P_n \vdash v_1 \Lambda v_{n} \vdash R \vdash v_1 \Lambda v_{n}$

$= C_n \vdash R \vdash v_1 \Lambda v_{n}$,

calling $R = v_n \Lambda v_{n+1} \vdash v_1 \Lambda v_{n+1}$, $C_n$ is inductive. □
Corollary 4.21. $S_n$ is inductive.

Proof. Same as corollary [4.20]. □

Theorem 4.22. if $S_n = S_{n-1} \dashv \varepsilon$ and $S'_m = S'_{m-1} \dashv \bar{\varepsilon}$, then

$$S_n \dashv S'_m \dashv \bar{\varepsilon} = S_{n-1} \dashv S'_{m-1}.$$ 

Proof. first we use the definitions

$$S_n \dashv S'_m \dashv \bar{\varepsilon} = (S_{n-1} \dashv \varepsilon) \dashv (S'_{m-1} \dashv \bar{\varepsilon}) \dashv \bar{\varepsilon}$$

$$= (S_{n-1} \dashv S'_{m-1}) \dashv (\varepsilon \dashv \bar{\varepsilon}) \dashv \bar{\varepsilon}$$

$$= S_{n-1} \dashv S_{m-1} \dashv (\varepsilon \dashv \bar{\varepsilon})$$

$$= S_{n-1} \dashv S_{m-1} \dashv \phi$$

$$= S_{n-1} \dashv S_{m-1}$$

then, we only use idempotency on edges and the axiom of inverse element. □

Theorem 4.23. If $V = V' \dashv V''$ where $V' = v_1 \dashv \cdots \dashv v_j$, $V'' = v_j \dashv \cdots \dashv v_n$ where $j \in \{1, \ldots, n\}$, then

$$S_n = S'_j \dashv S''_{n-j+1}.$$ 

Proof. Using the axiom of distributivity and asociativity, and the hypothesis, the proof is obvious. □

Before we present the next definition, lets define the following concepts

Definition 4.24. If $f(v_1, \ldots, v_n) = \Gamma$ is a conective form where $f : G^n \rightarrow G$, we will call Conective Form Complement to

$$\Gamma^c = K_n \dashv \bar{\Gamma}$$

Definition 4.25. If $\Gamma$ is a Conective Form, we will call a Star Composed Form to

$$\Gamma_s = N_n \bar{\Lambda} N_n \dashv \bar{\Gamma^c}$$

Example 4.26. Let's say that we have a conective form

$$\Gamma = v_1 \bar{\Lambda} v_2 \bar{\Lambda} v_3 \dashv v_3 \bar{\Lambda} v_4.$$ 

The complemet of $\Gamma$, using the definition will be:

$$\Gamma^c = N_4 \bar{\Lambda} N_4 \dashv (v_1 v_2 \bar{\Lambda} v_3 \dashv v_3 \bar{\Lambda} v_4)$$

$$= v_1 \bar{\Lambda} v_2 \bar{\Lambda} v_3 \dashv v_3 \bar{\Lambda} v_4$$

$$= v_1 \bar{\Lambda} v_2 \bar{\Lambda}.$$ 

Hence, the SCF:

$$\Gamma_s = N_4 \bar{\Lambda} N_4 \dashv (v_1 v_2 \bar{\Lambda} v_4)$$

$$= (v_1 \dashv v_2 \dashv v_3 \dashv v_4) \bar{\Lambda} (v_1 \dashv v_2 \dashv v_3 \dashv v_4) \dashv v_1 \bar{\Lambda} v_4 \dashv v_4 \bar{\Lambda} v_2$$

$$= v_1 \bar{\Lambda} v_2 \bar{\Lambda} v_3 \dashv v_2 \bar{\Lambda} v_3 \dashv v_3 \bar{\Lambda} (v_1 \dashv v_2 \dashv v_4) \dashv v_4 \bar{\Lambda} v_3.$$
Definition 4.27. If $V = v_1 \dashv \cdots \dashv v_n$, with $S_n$ defined as usual, for $f : G \to G$, $f(S_n) = S'_m$, if
\[ \text{card}(V) = \text{card}(V'), \]
With card, defined as the cardinality of the star.

Definition 4.28. The graphs $\Gamma$ and $\Gamma'$ will be isomorphic (ordered form maximum to minimum star by cardinality) if there is some $f : G \to G$, lineal to $\dashv \vdash$ that
\[ f(\Gamma_s) = \Gamma'_s. \]

Example 4.29. Let suppose we have the graphs $\Gamma = v_1 \Lambda v_2 \Lambda v_3 \dashv v_3 \Lambda v_4$ and $\Gamma' = w_1 \Lambda (w_2 \dashv w_3 \dashv w_4) \dashv w_2 \Lambda w_4$. Applying the definition 4.25 in both, we have
\[ \Gamma_s = v_1 \Lambda (v_2 \dashv v_3) \dashv v_2 \Lambda (v_1 \dashv v_3) \dashv v_3 \Lambda (v_1 \dashv v_2 \dashv v_4) \dashv v_4 \Lambda v_3 \]
\[ \Gamma'_s = w_1 \Lambda (w_2 \dashv w_3 \dashv w_4) \dashv w_2 \Lambda (w_3 \dashv w_4) \dashv w_3 \Lambda w_1 \dashv w_4 \Lambda (w_1 \dashv w_2), \]
as we see, ordering by maximum to minimum star and applying a function to $\Gamma$ (lineal to $\dashv \vdash$), the stars have equal cardinality, so, we accually have $f(\Gamma_s) = \Gamma'_s$.

Theorem 4.30. If $\Gamma^c$ is the complement of $\Gamma$ with $n$ vertex both, then
\[ \Gamma^c \dashv \vdash \Gamma = K_n. \]
Proof. Using the definition of complementary graph
\[ \Gamma^c \dashv \vdash \Gamma = (K_n \dashv \vdash \Gamma) \dashv \vdash \Gamma = K_n \dashv \vdash (\bar{\Gamma} \dashv \vdash \Gamma) = K_n \dashv \vdash \phi = K_n. \]
the graph and the complement make the complete graph. \hfill \square

5. A brief view of applications on multi, pseudo an oriented graphs

5.1. A reminder of the definitions. In many mathematical bibliography, graphs seems to be confused with other kind of objects like multi graphs, pseudo graphs and oriented graps. The truth is, there are conceptual differences, of which we are going to make a short remind to the reader.

Definition 5.1. A graph $G = (V, E)$ is called multigraph if some edges could be equal; between two nodes, can exist many edges.

Definition 5.2. A graph is called pseudograph if there are edges with the form $\{a, a\}$, but no multiedges of the canonical form.

Definition 5.3. A graph with the form $G = (V, E)$ is called oriented if the edges of $E$ have the form $e = (v, w)$, which is an ordered pair of vertexes.
5.2. Arithmetical Graphs. Wolfram, in an article referred at Pseudographs [5], referred as a graph with loops an multiedges. For some authors, pseudographs and graphs are deeply connected by the idea of multiset. But the problem was that the definition of those graphs only consider multiedges but no multivertexes, by that reason there is no posibility to define precisely the operation of union.

In 2003, Wildberger [6] presented a work proposing an alternative form to treat multisets by using linear notation. In that work, he propose a third operation on sets: the sum, were elements of two sets A and B just add in even if elements of both repeat. Let’s give a simple example. Let’s define the multisets A and B as

\[ A = \{a, a, b\} \]
\[ B = \{b, b, c\} \]

Then

\[ A + B = \{a, a, b, b, b, c\} \]

If we add antisets, we will have something very close to the arithmetical structure of \( \mathbb{Z} \) with the operation sum, defined as an abelian group. In the work of Carroll, there is an extension of the concept of negative sets to negative numbers that acctually shows how group theory can be constructed using the new extension to ZF axiomatic.

Multisets are linear, this is, for an external operation product in \( \mathbb{Z} \)

\[
\begin{align*}
(1) & \quad (n + m)S = nS + mS \\
(2) & \quad (nm)S = n(mS) \\
(3) & \quad n(S + S') = nS + nS' \\
(4) & \quad 1S = S
\end{align*}
\]

If the reader is interested, a deepest analisis of this structure of multisets is avaiable on the mencioned work.

Following this concept closer, we will observe that if we have a graph \( G = (V, E) \) the definition of graph sum extend not only to the edges but to the vertexes. Now, if we consider the definition on Wildbergers work, then we will have the folowing definition.

Definition 5.4. Let’s say that an arithmetical graph is such graph where \( V \) and \( E \) are multisets, with \( V \) multiset or vertexes and \( E \) multiset of the non ordered pairs of vertexes or edges.

Now, lets continue with the change of our previous algebra.

Definition 5.5. A set \( \Pi \) with the operations \( \vdash \vdash \) and \( \Lambda \) is called Arithmetical link if is a link algebra, but where axiom (4) is \( \vdash \vdash \phi = v, \vdash \Lambda \phi = \phi \), and both operations are not idempotent, with an external operation (multiplication) on \( \mathbb{Z} \) (is linear).
the theorems remain equal, the only variation of this algebra is the introduction of the concept of Vertex and Edge Engrosure, which includes the properties of numbers in graphs.

**Definition 5.6.** we will call the relation \( \prec \) **Engrosure**, where \( \forall n, m \in \mathbb{Z} \) and \( v \in \Pi \) we have \( n(v) \prec m(v) \) if \( n < m \).

is not too difficult to see that if \((\Pi, \models)\) is a group, \((\Pi, \prec)\) is an equivalence relation. The reader can easily prove the reflexivity, symmetry and transitivity.

**Definition 5.7.** we will call **Inverse vertex** to 
\[ (-1)v := \tilde{v}. \]

**Definition 5.8.** We will call a **Loop** to 
\[ v^\sigma := v \hat{\Lambda} v. \]

there is a theorem we want to add to this structure, probably it is obvious to demonstrate, but it is worth to be written.

**Theorem 5.9.** For an edge \( e = v \hat{\Lambda} w \) with \( n \in \mathbb{Z} \)
\[ ne = (nv) \hat{\Lambda} w = v \hat{\Lambda} (nw). \]

**Proof.** we have 
\[ n(v\hat{\Lambda}w) = v\hat{\Lambda}w \models v \hat{\Lambda}w = v\hat{\Lambda}(w \models w) = v\hat{\Lambda}(nv) \]
the other case is analogous. \( \square \)

**Example 5.10.** Let’s say we have the multigraph
\[ \Pi = 2(v_1 \hat{\Lambda} v_2) \models 2(v_2 \hat{\Lambda} v_3) \models v_4 \hat{\Lambda}(v_1 \models v_2 \models v_3). \]

**Using the linearity** he have:
\[ \Pi = 2(v_1 \hat{\Lambda} v_2) \models v_2 \hat{\Lambda} v_3) \models v_4 \hat{\Lambda}(v_1 \models v_2 \models v_3), \]

**Using the definition of Path and star:**
\[ \Pi = 2(P_3) \models S_3. \]

This example is an homage to Bernhard Euler, to his famous solution of the Koenisberg bridge problem presented on his work of 1736 *Solutio problematis ad geometriam situs pertinentis.*
5.3. **Oriented and mixed graphs.** This subsection will be briefest than others, the reason is that the definition introduced is short. As we said in the subsection 5.1, an oriented graph is defined as a graph $G = (V, E)$ where $E$ is an ordered pair of vertexes. Therefore, the only thing we will define before to show the definition of oriented link algebra, is the following

**Definition 5.11.** Let's have $(x,y)$ with Kuratowski’s definiton

$$(x, y) := \{\{x\}, \{x, y\}\},$$

We will call **Oriented Twist** to

$$(x, y) \overrightarrow{\circ} = (y, x).$$

A more precise definition with Set/antiset theory would be

$$(x, y) \overrightarrow{\circ} = (x, y) \cup \{\tilde{x}, \{y\}\},$$

where $\{x\} = A$ and $\tilde{x} = \tilde{A}$.

Now, let’s define An Oriented Link Algebra

**Definition 5.12.** An **Oriented Link Algebra** is a set $\Gamma$ with operations $\vdash \bowtie, \vec{\Lambda}$ and $\overrightarrow{\circ}$ (unitary), that satisfies the axioms of a Link Algebra except commutativity for the operation $\vec{\Lambda}$ satisfying instead

1) $v \vec{\Lambda} w = w \vec{\Lambda} v$

2) $(v \vec{\Lambda} w) \overrightarrow{\circ} = v \vec{\Lambda} w$

Basically, it works same as a link algebra, with the same theorems and definitions.

For a mixed graphs the definition is as follow

**Definition 5.13.** An **Mixed Link Algebra** is a set $\Gamma$ with the operations $\vdash \bowtie, \vec{\Lambda}, \circ$ where

1) $(\Gamma, \vdash \bowtie, \vec{\Lambda})$ is a Link Algebra.

2) $(\Gamma, \vdash \bowtie, \vec{\Lambda}, \circ)$ is a Oriented Link Algebra.

To finish the exposition of this concept we will give two last examples.

**Example 5.14.** Let’s have the oriented graph

$$\Gamma = w_1 \vec{\Lambda} v_1 \vdash v_1 \vec{\Lambda} v_2 \vdash v_2 \vec{\Lambda} v_3 \vdash v_1 \vec{\Lambda} v_4 \vdash v_4 \vec{\Lambda} v_3$$

using the concept of antisymmetric commutativity

$$\Gamma = w_1 \vec{\Lambda} v_1 \vdash v_1 \vec{\Lambda} v_2 \vdash v_2 \vec{\Lambda} v_3 \vdash v_4 \vec{\Lambda} v_1 \vdash v_3 \vec{\Lambda} v_4$$

**Example 5.15.** Let’s have the mixed graph

$$\Gamma = v_1 \vec{\Lambda} v_2 \vdash v_2 \vec{\Lambda} v_1 \vdash v_3 \vec{\Lambda} v_3.$$

Where we can identify a circular vinculation and a simple vinculation.
5.4. **As an Epilogue.** For almost 200 years, graphs had a minor status in the world of mathematics, being just the shadow of combinatorics, being only consulted when combinatorial arithmetic fails. George Boole, the father of modern logic, once said that in a near future, mathematics will be not mathematics of numbers, but of abstract objects beyond numbers, opening the view to a new world where there is no center in the mathematical universe: just objects, operations, lattices and who knows what other concepts to be defined and discover.

Boole as same as Sassure (father of modern semiotics), observe that Mathematical symbols **are** if there is a meaning that support them, an essence that allow to work the abstraction as it were concrete, like the Demiurgos of Plato’s Timeo, who commiserating of our material universe, decided to printed material copies from the universe of ideas. **Demiurgos** means **Artisan** in greek, and that is the essence of the work of a mathematitian: be the artisan of a never ending sculpture, the diachronically undefined but synchronously defined mathematical Rodin’s Dante: thinking of the *commedia della ragione* in the top of the gate of hell.

Le Graphe est mort, vive le Graphe!
