ON THE $K(\pi, 1)$-PROBLEM FOR RESTRICTIONS OF COMPLEX REFLECTION ARRANGEMENTS

NILS AMEND, PIERRE DELIGNE, AND GERHARD RÖHRLE

Abstract. Let $W \subset \text{GL}(V)$ be a complex reflection group, and $\mathcal{A}(W)$ the set of the mirrors of the complex reflections in $W$. It is known that the complement $X(\mathcal{A}(W))$ of the reflection arrangement $\mathcal{A}(W)$ is a $K(\pi, 1)$ space.

For $Y$ an intersection of hyperplanes in $\mathcal{A}(W)$, let $X(\mathcal{A}(W)Y)$ be the complement in $Y$ of the hyperplanes in $\mathcal{A}(W)$ not containing $Y$. We hope that $X(\mathcal{A}(W)Y)$ is always a $K(\pi, 1)$. We prove it in case of the monomial groups $W = G(r, p, \ell)$. Using known results, we then show that there remain only three irreducible complex reflection groups, leading to just eight such induced arrangements for which this $K(\pi, 1)$ property remains to be proved.

1. Introduction

An arrangement in a vector space $V$ is a finite set of homogeneous hyperplanes in $V$. For integers $\ell \geq 2$, $0 \leq k \leq \ell$ and $r \geq 1$, we define $\mathcal{A}_{k}^{\ell}(r)$ to be the arrangement in the complex vector space $\mathbb{C}^{\ell}$ (coordinates $y_{1}, \ldots, y_{\ell}$) consisting of the first $k$ coordinate hyperplanes $y_{a} = 0$ $(1 \leq a \leq k)$ and of the hyperplanes $y_{i} = \zeta y_{j}$ for $i \neq j$ and $\zeta$ an $r^{\text{th}}$ root of unity.

For $\mathcal{A}$ an arrangement in a complex vector space $V$, we define $X(\mathcal{A})$ to be the complement in $V$ of the union of the hyperplanes in $\mathcal{A}$. We say that the arrangement $\mathcal{A}$ is of $K(\pi, 1)$ type, or a $K(\pi, 1)$-arrangement, if $X(\mathcal{A})$ is a $K(\pi, 1)$, that is if the homotopy groups $\pi_{i}$ of $X(\mathcal{A})$ are trivial for $i \geq 2$, or equivalently if the universal covering of $X(\mathcal{A})$ is contractible. Our main result is the following.

2010 Mathematics Subject Classification. Primary 20F55, 52C35, 14N20; Secondary 13N15.

Key words and phrases. Complex reflection groups, reflection arrangements, restricted arrangements, $K(\pi, 1)$-arrangements, Eilenberg–MacLane space.
Theorem 1. The arrangements $\mathcal{A}_k^\ell(r)$ are of $K(\pi, 1)$ type.

For $V$ a finite dimensional complex vector space, an element $s$ of $\text{GL}(V)$ is a complex reflection if its fixed point set is a hyperplane. This hyperplane is called the mirror of $s$. If $W \subset \text{GL}(V)$ is a complex reflection group, that is a finite subgroup of $\text{GL}(V)$ generated by complex reflections, the arrangement $\mathcal{A}(W)$ is the set of mirrors of the complex reflections in $W$. The arrangements so obtained are the reflection arrangements. Note that for $\ell \geq 3$, $r \geq 2$, and $0 < k < \ell$, the $\mathcal{A}_k^\ell(r)$ are not reflection arrangements.

If $X \subset V$ is the intersection of some hyperplanes belonging to an arrangement $\mathcal{A}$ in $V$, the arrangement $\mathcal{A}^X$ induced by $\mathcal{A}$ on $X$ is the set of the traces on $X$ of the hyperplanes in $\mathcal{A}$ not containing $X$. The arrangements induced by $\mathcal{A}$ are the arrangements so obtained.

The $K(\pi, 1)$ property is not generic among all arrangements. A generic complex $\ell$-arrangement $\mathcal{A}$ for $\ell \geq 3$ is an $\ell$-arrangement with at least $\ell + 1$ hyperplanes and the property that the hyperplanes of every subarrangement $\mathcal{B} \subseteq \mathcal{A}$ with $|\mathcal{B}| = \ell$ are linearly independent. It follows from work of Hattori [Ha75] that generic arrangements are never $K(\pi, 1)$.

By Deligne [Del72], complexified simplicial arrangements are $K(\pi, 1)$. Likewise for complex fiber-type arrangements, cf. [FR85] and [Ter86]. As restrictions of simplicial (resp. fiber-type) arrangements are again simplicial (resp. fiber-type), the $K(\pi, 1)$-property of these kinds of arrangements is inherited by their restrictions. However, we emphasize that in general, a restriction of a $K(\pi, 1)$-arrangement need not be $K(\pi, 1)$ again, see [AMR18] for examples of this kind.

Along with the previously known instances of $K(\pi, 1)$ restrictions of reflection arrangements, it follows from Theorem 1 that only a small number of restrictions of rank 3 and 4 of arrangements associated to some non-real exceptional groups remain unresolved. This provides strong evidence towards the following.

**Hope.** Any arrangement induced from a reflection arrangement $\mathcal{A}(W)$ is a $K(\pi, 1)$. 
This hope reduces to the case of arrangements induced from reflection arrangements \( \mathcal{A}(W) \), for \( W \subset \text{GL}(V) \), such that \( V \) is an irreducible representation of \( W \). In what follows we, sometimes tacitly, only consider this case.

The hope is true for \( W \) the complexification of a real reflection group. Indeed, after reduction to the case where the intersection of all mirrors is reduced to \( \{0\} \), such an \( \mathcal{A}(W) \) is the complexification of a simplicial arrangement ([Bou68] V 3.9). The property of being the complexification of a simplicial arrangement is stable by induction, and one applies Deligne [Del72].

All reflection arrangements \( \mathcal{A}(W) \) are of \( K(\pi, 1) \) type. This theorem is due to Fadell and Neuwirth [FN62], Brieskorn [Br73], Nakamura [Nak83], Orlik and Solomon [OS88] in special cases, and to Bessis [Be15] in the general case.

It follows from Theorem 1 that the arrangements induced from the reflection arrangements \( \mathcal{A}_0^0(r) \) and \( \mathcal{A}_0^1(r) \) are \( K(\pi, 1) \)-arrangements.

Using those results and the trivial fact that for \( \dim V \leq 2 \) any arrangement is of \( K(\pi, 1) \) type, one gets our hope in all but finitely many cases. More precisely, by Theorem 1, our discussion above, and from the classification of the irreducible complex reflection groups, our hope reduces to 13 instances when the underlying reflection group is of exceptional type. Following [OS82], we label the \( W \)-orbit of \( Y \in L(\mathcal{A}(W)) \) by the pair \((G_n, T)\), where \( G_n \) is the relevant reflection group, in the Shephard-Todd numbering [ST54], and \( T \) is the type of the reflection subgroup of \( G_n \) fixing pointwise the intersection of mirrors \( Y \) we are considering. In our cases, the type \( T \) determines \( Y \) up to \( G_n \)-conjugacy. The 13 instances are \((G_{29}, A_1)\), \((G_{31}, A_1)\), \((G_{32}, C(3))\), \((G_{33}, A_1)\), \((G_{33}, A_1^2)\), \((G_{33}, A_2)\), \((G_{34}, A_1)\), \((G_{34}, A_1^2)\), \((G_{34}, A_2)\), \((G_{34}, A_2^3)\), \((G_{34}, A_1 A_2)\), \((G_{34}, A_3)\), and \((G_{34}, G(3,3,3))\), see [OS82, §3, App.]. The cases \((G_{32}, C(3))\) and \((G_{34}, G(3,3,3))\) can be handled as follows. The lattices of intersections of \((G_{32}, C(3))\) and \((G_{34}, G(3,3,3))\) are both isomorphic to the lattice of \( \mathcal{A}(G_{26}) \), cf. [OT92, App. D]. Viewed projectively, the arrangement \( \mathcal{A}(G_{26}) \) is the extended Hessian configuration.
of 21 lines in $\mathbb{P}^2(\mathbb{C})$, cf. [OT92, Ex. 6.30]. It is classical that this configuration, as a set of 21 lines, is determined by its combinatorics, i.e. by the isomorphism class of the corresponding lattice: the arrangements $(G_{32}, C(3))$ and $(G_{34}, G(3, 3, 3))$ are linearly isomorphic to the reflection arrangement $\mathcal{A}(G_{26})$. Therefore, since $\mathcal{A}(G_{26})$ is a $K(\pi, 1)$-arrangement, so are the restrictions $(G_{32}, C(3))$ and $(G_{34}, G(3, 3, 3))$. Moreover, since the localization of a $K(\pi, 1)$-arrangement is again $K(\pi, 1)$ (cf. [Pa93, Lem. 1.1]), and since $G_{33}$ is a parabolic subgroup of $G_{34}$ ([OS82, Table 11]), the three instances stemming from $G_{33}$ are localizations of the corresponding restrictions from $G_{34}$. So verifying our Hope reduces to the remaining 8 restrictions on the list above.

2. Method of proof

A reasonable topological space $X$, for instance a manifold or a CW complex, is a $K(\pi, 1)$ if and only if it is connected (hence, by definition, not empty) and if for some (equivalently, any) base point $o \in X$, the homotopy groups $\pi_i(X, o)$ are trivial for $i \geq 2$. The long exact sequence of homotopy groups implies the

Lemma 2.1. Suppose that $X$ is connected and that $f: X \to Y$ is a fibration. Then, if $Y$ is a $K(\pi, 1)$ and if some connected component of some fiber $f^{-1}(y)$ is a $K(\pi, 1)$, so is $X$.

We fix $k, \ell, r$ as in Theorem 1. We simply write $\mathcal{A}$ for the arrangement $\mathcal{A}_k^\ell(r)$ in $\mathbb{C}^\ell$. The coordinates of $\mathbb{C}^\ell$ are denoted $y_1, \ldots, y_\ell$.

Let us consider another copy of $\mathbb{C}^\ell$, with coordinates $x_1, \ldots, x_\ell$. Let $V$ be the quotient of this vector space $\mathbb{C}^\ell$ by its diagonal subspace $\mathbb{C}$. The action of the symmetric group $S_\ell$ on $\mathbb{C}^\ell$ passes to the quotient. So do the linear forms $x_i - x_j$. The arrangement $A_{\ell-1}$ on $V$ is the set of the hyperplanes $x_i - x_j = 0$ of $V$. It is the reflection arrangement $\mathcal{A}(S_\ell)$ defined by the action of $S_\ell$ on $V$. It is of $K(\pi, 1)$ type, and the fundamental group of $X(A_{\ell-1})$ is the pure braid group on $\ell$ strands.
The $z_i := x_i - x_\ell$ (1 $\leq i \leq \ell - 1$) form a system of coordinates on $V$. In this system of coordinates, the arrangement $A_{\ell - 1}$ is the arrangement $A_{\ell - 1}^{\ell - 1}(1)$ consisting of the coordinate hyperplanes $z_i = 0$ and of the hyperplanes $z_i = z_j$ for $i \neq j$.

Our *deus ex machina* is the composite map

$$f: \mathbb{C}^\ell(\text{coordinates } y_i) \longrightarrow \mathbb{C}^\ell(\text{coordinates } x_i) \longrightarrow V,$$

where the first map in (2.2), or rather its graph, is given by

$$x_i = y_1 \cdots y_k y_i^r.$$

It is equivariant for the subgroup $S_k \times S_{\ell - k}$ of $S_\ell$, acting on $\mathbb{C}^\ell$ and on $V$: the coordinates $y_1, \ldots, y_k$, as well as $y_{k+1}, \ldots, y_\ell$, play symmetric roles.

The inverse image by $f$ of the union of the hyperplanes in $A_{\ell - 1}$ is the union of the hyperplanes in $\mathcal{A}$. Indeed, the inverse image of the hyperplane $x_i - x_j = 0$ is the union of the coordinate hyperplanes $y_a = 0$ for $1 \leq a \leq k$, and of the hyperplanes $y_i = \zeta y_j$ for $\zeta$ an $r^{th}$ root of unity.

In the coordinate system $(z_i)$ of $V$, the map (2.2) is given by

$$z_i = y_1 \cdots y_k (y_i^r - y_\ell^r).$$

It induces a map, still denoted by $f$

$$f: X(\mathcal{A}) \longrightarrow X(A_{\ell - 1}).$$

**Theorem 2.** The map $f: X(\mathcal{A}) \longrightarrow X(A_{\ell - 1})$ realizes $X(\mathcal{A})$ as a smooth fiber space over $X(A_{\ell - 1})$.

A consequence of Theorem 2 is that the fibers of $f: X(\mathcal{A}) \longrightarrow X(A_{\ell - 1})$ are non empty smooth affine curves. The connected components of such a curve are again smooth and affine, hence are $K(\pi, 1)$. Indeed, the only Riemann surface which is not a $K(\pi, 1)$ is the
sphere. As $X(\mathcal{A})$ is connected and $X(A_{\ell-1})$ is a $K(\pi, 1)$, Theorem 1 is a consequence of Theorem 2 and Lemma 2.1.

The proof of Theorem 2 is given in the next section, where we use the following lemma.

**Lemma 2.6.** Let $M$ and $B$ be $C^\infty$-manifolds, $N$ a closed submanifold of $M$ and $f: M \to B$ a morphism. If $f$ is proper, submersive, and with a restriction to $N$ submersive, then, locally on $B$, $f: (M, N) \to B$ is isomorphic to a projection $(M_0 \times B, N_0 \times B) \to B$. A fortiori, $f: M - N \to B$ is a smooth fiber bundle.

For $N$ empty, the lemma first appeared without proof in [Ehr47, Prop. 1]. For the sake of completeness, we now explain the folklore proof of Lemma 2.6 in the case when $N$ is empty, and then explain how to extend it to the general case.

The question being local on $B$, we may assume that $B$ is of the form $]-1,1[\ell$ (coordinates $t_1, \ldots, t_\ell$), and we proceed by induction on $\ell$, the case $\ell = 0$ being trivial. The vector field $\partial_{t_\ell}$ on $B$ can be lifted to a vector field $X$ on $M$. Indeed, such a lifting exists locally on $M$, and one uses a partition of unity to get a global lifting from local liftings. As $df(X) = \partial_{t_\ell}$, by integrating $X$ we obtain isomorphisms between the fibers of $f$ at $(t_1, \ldots, t_{\ell-1}, 0)$ and $(t_1, \ldots, t_{\ell-1}, t_\ell)$. These isomorphisms identify $M \to B$ with the pull-back by $]-1,1[\ell \to ]-1,1[\ell-1$ of the restriction of $M \to B$ to $]-1,1[\ell-1 \times \{0\} \subset B$. One concludes using the induction hypothesis.

The proof of Lemma 2.6 is identical: one just needs to choose the lifting $X$ of $\partial_{t_\ell}$ to be tangent to $N$.

### 3. Proof of Theorem 2

The fiber $F_z$ at $z \in X(A_{\ell-1})$ of $f: X(\mathcal{A}) \to X(A_{\ell-1})$ is given, in $C^\ell$, by the equations

\begin{equation}
\left.y_1 \cdots y_\ell (y_i^r - y_\ell^r) = z_i \quad (i = 1, \ldots, \ell - 1)\right.
\end{equation}
Any of these equations implies that \( y_1, \ldots, y_k \neq 0 \). Their system is equivalent to the first equation

\[(2) \quad y_1 \cdots y_k (y_1^r - y_\ell^r) = z_1,\]

supplemented by the equations

\[(3) \quad \frac{1}{z_1} (y_i^r - y_\ell^r) = \frac{1}{z_i} (y_\ell^r - y_i^r) \quad (2 \leq i \leq \ell - 1)\]

which are homogeneous of degree \( r \) in the \( y_i \).

Let us compactify \( C^\ell \) into \( \mathbb{P}^\ell(\mathbb{C}) \). In \( \mathbb{P}^\ell(\mathbb{C}) \), we will use the homogeneous coordinates \( y_0, y_1, \ldots, y_\ell, y_0 = 0 \) being the equation of the hyperplane at infinity added to \( C^\ell \). To compactify the fiber \( F_z \) it suffices to take the projective variety \( \overline{F}_z \) defined by the homogeneous equations (3), and by (2) made homogeneous, that is

\[(2') \quad y_1 \cdots y_k (y_1^r - y_\ell^r) = z_1 y_0^{k+r},\]

an equation homogeneous of degree \( k + r \) in the \( y_i \).

It will be convenient to define \( z_\ell := 0 \). With this notation, (3) tells that the \( y_i^r - y_\ell^r \) are proportional to the \( z_i - z_\ell \) and it follows that all \( y_i^r - y_j^r \) are proportional to the \( z_i - z_j \) : for some \( u, y_i^r - y_j^r = u(z_i - z_j) \).

To compute the intersection of this compactification \( \overline{F}_z \) with the hyperplane at infinity \( H_\infty \), it suffices to put \( y_0 \) equal to 0, and to view \( y_1, \ldots, y_\ell \) as projective coordinates for the hyperplane at infinity. We obtain \( kr^{\ell-2} + r^{\ell-1} \) distinct points, as follows. One of the factors at the left side of (2') must vanish. If \( y_i = 0 \) (1 \( \leq i \leq k \)), the \( y_j^r = y_j^r - y_i^r \) are proportional to the \( z_j - z_i \), and we get the \( r^{\ell-2} \) points with coordinates

\[ (y_i = 0, y_j = (z_j - z_i)^{\frac{1}{r}}) \]
(to be taken up to multiplying by a common $r^{\text{th}}$ root of 1).

If $y_1^r - y_\ell^r = 0$, all $y_i^r - y_j^r$ must vanish. We get the $r^{\ell-1}$ points “all $y_i$ are an $r^{\text{th}}$ root of 1”, again taken up to multiplication by a common $r^{\text{th}}$ root of 1.

**Lemma 3.1.** The compactification $\overline{F}_z$ of the fiber $F_z$ of $f$ at $z$ defined by the $(\ell - 1)$ equations $(2')$ and $(3)$ is a complete intersection curve, smooth at infinity, and meeting transversally the hyperplane at infinity $H_\infty$.

**Proof.** If $\overline{F}_z$ had an irreducible component of dimension $> 1$, the intersection of this component with $H_\infty$ would be of dimension $> 0$, contradicting the finiteness of $\overline{F}_z \cap H_\infty$. It follows that $\overline{F}_z$, being defined by $(\ell - 1)$ equations, is a complete intersection curve. By Bezout, the number of points in $\overline{F}_z \cap H_\infty$, each counted with its intersection multiplicity, is $(k + r)^{n-2}$. It follows that each intersection multiplicity is one. As $\overline{F}_z$ and $H_\infty$ are local complete intersections, this implies that $\overline{F}_z$ is smooth at each point of $\overline{F}_z \cap H_\infty$, and that the intersection is transversal. \hfill $\square$

It follows from Lemma 3.1 that $\overline{F}_z$ is simply the closure of $F_z$ in $\mathbb{P}^\ell(\mathbb{C})$, and that the curve $\overline{F}_z$ is generically reduced, that is generically smooth, as a non reduced component would intersect $H_\infty$.

The same argument shows that

**Lemma 3.2.** For $k + 1 \leq i \leq \ell$, the curve $\overline{F}_z$ is smooth at each of its intersection points with the hyperplane $y_i = 0$.

**Proof.** It suffices to show that the number of intersection points is $(k + r)^{n-2}$. As the hyperplanes $y_i = 0$ ($k + 1 \leq i \leq \ell$) play symmetric roles, it suffices to consider the case of the hyperplane $y_\ell = 0$. The equations (3) tell us that $(y_1^r, \ldots, y_{\ell-1}^r)$ is proportional to $(z_1, \ldots, z_{\ell-1})$, while by $(2')$ they cannot be all zero, as otherwise $y_0$ would be zero too. If we fix the indeterminacy “multiplication by a common constant” by requiring $y_{\ell-1}$ to be a
specified root of \( z_{\ell-1} \), (3) tells that each \( y_i \) (\( 1 \leq i \leq \ell - 2 \)) is an \( r \)th root of \( z_i \). This gives \( r^{\ell-2} \) possibilities, while (2') leaves \( (k + r) \) possibilities for \( y_0 \). \( \square \)

**Lemma 3.3.** The curve \( \overline{F_z} \) is smooth.

**Proof.** By Lemma 3.1, it suffices to show that \( F_z \) is smooth. By (2), \( F_z \) does not intersect the hyperplanes \( y_i = 0 \) for \( 1 \leq i \leq k \). By Lemma 3.2, it hence suffices to check that in the open set where none of the \( y_i \) vanishes, \( F_z \) is smooth. Locally on \( (\mathbb{C}^*)^{\ell} \), we can take as local coordinates the \( Y_i = y_i^r \). In these local coordinates, (3) tells us that \( F_z \) is on the surface \( Y_i = az_i + b \) (coordinates \( a, b \)). The last equation (2) becomes

\[
\prod_{i=1}^{k} (az_i + b)^{\frac{1}{r}} \cdot az_1 = z_1
\]

for some branches of the \( r \)th roots. It follows that \( a \neq 0 \), and that \( F_z \) is contained in the curve of the plane \( (a, b) \)

\[
a^r \prod_{i=1}^{k} (az_i + b) = 1.
\]

One concludes by invoking the well known

**Lemma 3.4.** If \( F(a_1, \ldots, a_n) \) is a homogeneous polynomial of degree \( d \geq 1 \), the hypersurface \( F(a_1, \ldots, a_n) = 1 \) is non singular.

By homogeneity, the hypersurfaces \( F = c \) are, for \( c \neq 0 \), all isomorphic. By Sard’s theorem, almost all are non singular. One could rather use the Jacobian criterion : at a point where \( F = 1 \), Euler’s identity

\[
\sum a_i \partial_i F = dF = d
\]

shows that not all \( \partial_i F \) can vanish.

If we now let \( z \) vary in \( X(A_{\ell-1}) \), we obtain a family of smooth complete intersection curves in the projective space \( \mathbb{P}^\ell(\mathbb{C}) \) completing \( \mathbb{C}^\ell \), transversal to the hyperplane at infinity. The total space is contained in \( \mathbb{P}^\ell(\mathbb{C}) \times X(A_{\ell-1}) \), and one applies Lemma 2.6 to it. \( \square \)
4. Complements

4.1. The projective completion $\overline{F}_z$ of the fiber $F_z$ of the fiber bundle $f : X(\mathcal{A}) \to X(A_{\ell-1})$ is a smooth complete intersection in $\mathbb{P}^{\ell}(\mathbb{C})$, of multidegree $(k + r, r, \ldots, r)$. As $\overline{F}_z$ is defined by $(\ell - 2)$ homogeneous equations, its complement $U$ is the union of $(\ell - 2)$ smooth open affine varieties of dimension $\ell$, so that $H^1_c(U) = 0$ and $H^0(\mathbb{P}^{\ell}(\mathbb{C})) \to H^0(\overline{F}_z)$: so $\overline{F}_z$ is connected. To see this, one could rather make an iterated application to the Lefschetz hyperplane theorem, again for $H^0$.

The canonical line bundle of a complete intersection $Y$ of degrees $(d_1, \ldots, d_{\ell-1})$ in $\mathbb{P}^{\ell}(\mathbb{C})$ is isomorphic to the restriction to $Y$ of $\mathcal{O}(\Sigma d_i - \ell - 1)$. In our case, it follows that the degree $2g - 2$ of the canonical line bundle of the curve $\overline{F}_z$ is given by

$$2g - 2 = (k + (r - 1)(\ell - 1) - 2)(k + r)^{\ell-2}.$$ 

The fiber $F_z$ is the complement in $\overline{F}_z$ of $(k + r)^{\ell-2}$ points. Its fundamental group is hence a free group with $N$ generators, where

$$N = 2g + \text{number of removed points} - 1$$

$$= (k + (r - 1)(\ell - 1) - 1) (k + r)^{\ell-2} + 1.$$ 

4.2. Each curve $\overline{F}_z$ contains at infinity the point $(0, 1, \ldots, 1)$. If $M \to X(A_{\ell-1})$ is the total space of the family of the $\overline{F}_z$ (contained in $\mathbb{P}^{\ell}(\mathbb{C}) \times X(A_{\ell-1})$), this common point gives us a section $s$ of the fiber bundle $M \to X(A_{\ell-1})$. The vertical tangent bundle, restricted to this section, is a trivial line bundle, because any line bundle on $X(A_{\ell-1})$ is trivial. Let $v$ be, along $s$, a nowhere vanishing section of the vertical tangent bundle. Pushing $s$ in the direction of $v$, one obtains a $C^\infty$ section of $X(\mathcal{A}) \to X(A_{\ell-1})$. The fundamental group of $X(\mathcal{A})$ is hence a semi-direct product of the fundamental group of the basis by the fundamental group of the fiber: a semi-direct product of the braid group on $\ell$ strands by the free group on $N$ generators.
