Effects of Fe$^{+2}$ and Fe$^{+3}$ in Pretreatment and Leaching on a Mixed Copper Ore in Chloride Media

María E. Taboada *, Pia C. Hernández, Aldo P. Padilla, Nathalie E. Jamett and Teófilo A. Graber

Abstract: A study of the pretreatment stage and subsequent leaching of a mixed copper ore with different chloride solutions containing iron was carried out. The first stage considered pretreatment tests to decide the best conditions. Two levels of each factor were analyzed, 20 and 50 kg/t of NaCl, 17 and 25 kg/t of H$_2$SO$_4$, 0 and 25 kg/t of Fe$_2$(SO$_4$)$_3$, 9.2H$_2$O, 0 and 25 kg/t of Fe$_2$SO$_4$, 7H$_2$O, and a curing time of 15 and 30 days. The results showed a significant effect of NaCl and curing time on the extraction, and less effect was found with the variation of acid and iron salts. The second stage included column leaching using a solution with 0.5 g/L of Cu$^{+2}$, 80 g/L of Cl$^{-}$, 10 g/L of H$_2$SO$_4$, and variable concentrations of ferric and ferrous ions (0 and 2 g/L). The best copper extraction of 80.2% was found considering a pretreatment of 30 days, 25 kg/t of H$_2$SO$_4$, 50 kg/t of NaCl, and a leaching solution concentration described previously with 2 g/L of Fe$^{+2}$. The results showed the leaching of all copper oxide species and 20% of the copper sulfide species. In addition, there was a reduction in the acid consumption as the resting time increases. Furthermore, to evaluate a possible decrease in time and acid in pretreatment and chloride in leaching, tests including 10 and 25 kg/t of H$_2$SO$_4$ and 1, 15, and 30 days of curing and a diminution of the NaCl concentration to 20 g/L (content from seawater) were executed. The results showed a significant effect on curing time below 15 days. Furthermore, the slight influence of the decrease of acid on copper extraction gives cost reduction opportunities. The diminution of chloride concentration (80 to 20 g/L) in leaching solution decreases the extraction from 79% to 66.5%. Finally, the Mellado leaching kinetic model was successfully implemented.

Keywords: pretreatment; chloride; ferric; ferrous; mixed copper ore; column leaching; seawater

1. Introduction
Copper oxide and copper sulfide ores are processed in hydrometallurgical and concentrator plants, respectively. Due to the nature of deposits and the deepening of the pits, there is a depletion of the oxide copper ores and greater presence of sulfide ores [1]. This situation has led to the study of new economically and environmentally feasible processes. Heap leaching in chloride media of copper sulfide ores has attracted increasing interest [2–5]. In arid regions, seawater or discarded brines can be used as leaching media [6–9].

Many authors concluded that chloride media is effective in copper sulfide ore dissolution for many reasons. The increase of the solubility of metallic ions such as copper and iron, the improvement in the redox properties of the system caused by the formation of chlorocomplexes and the stabilization of couple Cu$^{+1}$/Cu$^{+2}$, and the generation of porous layers in the surface of the ore allowing optimal diffusion of the leaching agents are some of them [2,6,10–15].

On the other hand, according to the Pourbaix diagram, copper sulfides as Chalcopyrite (CuFeS$_2$), Bornite (Cu$_3$FeS$_4$), Chalcocite (Cu$_2$S), and Covellite (CuS) need low pH (less than pH 4) and redox potentials above 0.4 V (SHE). These potential levels can be achieved
using oxidants as ferric ions in the leaching solution [16]. The couple Fe$^{+2}$/Fe$^{+3}$ variation can lead to modifications on the solution potential readily [17–20]. Diverse authors have studied these antecedents [21–26].

For example, Niu et al. [27] studied chalcocite column leaching using acid solutions containing ferric sulfate, obtaining a maximum of 80% at 30 °C after 250 h of leaching. The mechanism was described as a two-stage dissolution process, with the production of secondary covellite as an intermediate, according to Reactions (1) and (2).

\[
\text{Cu}_2\text{S} + 2\text{Fe}^{+3} \rightarrow \text{Cu}^{+2} + 2\text{Fe}^{+2} + \text{CuS} \tag{1}
\]
\[
\text{CuS} + 2\text{Fe}^{+3} \rightarrow \text{Cu}^{+2} + 2\text{Fe}^{+2} + S^0 \tag{2}
\]

On the other hand, Hashemzadeh et al. [28] studied and modeled the kinetics of chalcocite agitated leaching with ferric chloride. Additionally, the effects of parameters such as chloride, ferric, ferrous concentrations, ferric/ferrous ratio, temperature, and particle size were analyzed. Similarly to Niu et al. [27], the authors proposed a two-stage dissolution mechanism; the main difference is the production of non-stoichiometric compounds such as djurleite, digenite, anilite, and secondary covellite, among others, as products in the first stage (Reaction (3)). In the second stage, the non-stoichiometric compounds are oxidized, as seen in Reaction (4).

\[
\text{Cu}_2\text{S} + 4x\text{Fe}^{+3} \rightarrow \text{Cu}_{2(1-x)}\text{S} + 2x\text{Cu}^{+2} + 4x\text{Fe}^{+2} \tag{3}
\]
\[
\text{Cu}_{2(1-x)}\text{S} + 4(1-x)\text{Fe}^{+3} \rightarrow 2(1-x)\text{Cu}^{+2} + 4(1-x)\text{Fe}^{+2} + S^0 \tag{4}
\]

Based on the kinetics, it was concluded that the diffusion of ferric ions controlled the first stage. In contrast, the second stage was controlled by a combination of the ore decomposition and ferric reduction.

Additionally, Miki et al. [29] studied and compared the leaching kinetics of covellite, chalcocite, and digenite. The potential was controlled by varying the chloride and acid concentrations. The leaching rate is similar at 600 mV and 650 mV potentials, while at potentials below 500 mV, it is noticeably less. The leaching rates of chalcocite and digenite are faster than that of covellite. The secondary covellite can be leached at potentials above 550 mV, as was predicted previously.

Nicol and Zhang [30] and Nicol et al. [31] studied the cathodic reduction of Fe$^{+3}$ and Cu$^{+2}$ and the anodic oxidation of Fe$^{+2}$ and Cu$^{+1}$ in the leaching of several copper sulfides using chloride solutions.

The results showed variable reactivity of the minerals for Fe$^{+2}$ oxidation and Cu$^{+1}$ ions. At the studied conditions, passivation of the oxidation of Fe$^{+2}$ at high potentials occurs on all minerals, except pyrite. Low passivation of Cu$^{+1}$ oxidation occurs only in chalcopyrite and covellite at high potentials. The passivation of minerals oxidation cause is not established, but according to the authors, the passivation causes are the same in cuprous and ferrous ions. Similarly, the authors found variable reactivity of the sulfide minerals for the reduction of Fe$^{+3}$ and Cu$^{+2}$. The results showed that all minerals have greater reactivity for the reduction of Cu$^{+2}$ than Fe$^{+3}$.

In the case of chalcopyrite, the leaching at high potentials has been questioned (i.e., high ferric concentration in leaching solution). Studies show an inhibition of chalcopyrite at high ferric concentrations [16]. Conversely, ferrous ions increase the leaching kinetics [32,33].

Hiroyoshi et al. [34] found that the copper dissolution from chalcopyrite increases with the use of ferrous sulfate instead of ferric sulfate. Later, Hiroyoshi et al. [35] proposed a leaching model including ferrous ions in the leaching solution. The model included a two-stage process: first, the reduction of chalcopyrite to Cu$_2$S in the presence of ferrous ions. Second, the oxidation of Cu$_2$S to cupric ions and elemental sulfur via oxygen and/or ferric ions. Yang et al. [36] found that the chalcopyrite leaching increased with the redox
potential decrease. This condition was achieved with the increase of the ferrous ions. A 
\( \text{Cu}^{2+} \) and \( \text{Fe}^{2+} \) leaching system was more effective than a \( \text{Cu}^{2+} \) and \( \text{Fe}^{3+} \) system.

Along with the operational conditions described previously, implementing a pre-
treatment of the ore helps increase the extraction and reduce the leaching cycle. The 
pretreatment consists of agglomerate and acid curing of the ore. The agglomerate promotes 
the aggregation of the fine particles to avoid segregation and improves the percolation of 
the heap, whereas the acid curing inhibits the dissolution of impurities and accelerates the 
extractions \[37,38\].

The optimal curing and agglomeration conditions depend on the size distribution 
and the ore mineralogy. Cerda et al. \[39\] studied the pretreatment and leaching of a 
copper sulfide ore in a chloride media. The maximal copper extraction was 85% using a 
pretreatment stage and agitated leaching. Without the pretreatment, the extraction reached 
was 55% at the same leaching conditions. In a column leaching, the extraction reached 49% 
at room temperature.

Bahamonde et al. \[40\] found an increment in the copper extraction when a pretreat-
ment stage with sodium chloride and sulfuric acid was included in the process. The 
copper concentrate was composed of bornite and chalcopyrite in a proportion of 66.7% 
and 19.8%, respectively. They concluded that the efficiency of the pretreatment process 
depends majorly on the formation of hydrochloric acid in the mixture at the particle level.

Quezada et al. \[41\] and Velasquez-Yévenes et al. \[42\] studied the effect of pretreatment 
on different scenarios. In the case of leaching of secondary copper sulfide ores, it was 
demonstrated that the agglomeration with acid and chloride ions and curing for an exten-
sive period increases the copper extraction with a maximal extraction of 72% considering 
50 days of curing. Decreasing the time to 3 days reduces the copper extraction to 58%. Simi-
larly, the pretreatment helps to enhance the copper extraction from an ore compose majorly 
of chalcopyrite. Increasing the curing time from 15 to 80 days (and additionally 100 g/L of 
acid, 160 g/L of NaCl, and 0.5 g/L of \( \text{Cu}^{2+} \)) and considering 20 days of column leaching 
can approximately increase the extraction from 20 to 60%. The increase in chloride content 
can enhance the extraction by more than 20 percentage points at the studied conditions.

Undoubtedly, heap leaching of copper sulfide ores has been a matter of broad research 
to elucidate their mechanisms and controlling factors. One technique used to support the 
experimentation is the use of modeling techniques to forecast the metal production and the 
controlling variables. Several models have been developed, from a simple spreadsheet to 
complex phenomenological models \[43\]. The forecast metal extraction can be obtained from 
empirical data from other operations or extrapolated column leach tests. More complex 
spreadsheet-based models applied additional scale-up factors to improve the accuracy of 
the extractions from laboratory column testing \[44\] and/or complement the former models 
with the solution inventory from inside the heap at the end of the period. Phenomenological 
models can represent leaching processes incorporating the transport of liquid, gas, solutes, 
and heat into, through, and out the leaching heap at different time scales \[43\]. Examples of 
phenomenological models based on the characteristics mentioned previously can be found 
in \[45–49\].

On the other hand, Mellado et al. \[50–52\] developed a series of analytical models 
that, combined with phenomenology aspects, are used to interpolate and extrapolate the 
behavior of the heap. These models are suitable for scaling up the heap leach process of 
solids reactants from porous pellets producing accurate solutions for actual industry heap 
leach operations. Saldaña et al. \[53\] presented a methodology for evaluating heap leach 
incorporating discrete event simulation for feed mineral composition variation and the 
behavior of the heap, using the analytical models developed by Mellado.

This work aims to determine the effect of ferric and ferrous ions in a pretreatment 
stage with the subsequent leaching stage using a copper mixed ore in an acid–chloride 
media. The experimental design considered two sets of tests. The first set evaluates 
the addition of reagents such as sulfuric acid (17 and 25 kg/t), chloride (20 and 50 kg/t), 
ferric sulfate (0 and 25 kg/t), ferrous sulfate (0 and 25 kg/t), and the curing time (15 and
30 days) in the ore pretreatment. Once the best condition on pretreatment that maximizes the copper extraction is identified, the second set of tests is executed, evaluating the incorporation of ferric ions (0 or 2 g/L) or ferrous ions (0 or 2 g/L) into the leaching solution to continue increasing the copper extraction. In addition, a final evaluation of the pretreatment/leaching cycle and acidification is performed.

2. Materials and Methods

Mixed copper ore samples from Antofagasta Region in Chile are used. The ore size is reduced to −3/8” with P_{80} equal to 10.9 mm. The ore composition is obtained by inductively coupled plasma atomic emission spectroscopy (ICP-AES) and corroborated by atomic absorption spectrometry (AAS) (ICP-AES, ICPE-9000, Shimadzu, Tokyo, Japan); see Table 1. The total copper concentration is 0.44%, and the soluble copper concentration is 0.24% with 23.9 Kg H_{2}SO_{4}/T ore. Table 2 shows the mineral composition determined by optical microscopy. The most abundant mineral species is Atacamite, with 0.37%. The majority of copper insoluble species are Chalcopyrite, Chalcocite, and Covellite, corresponding in total to 0.2% of the ore sample. There is also Limonite in the sample, contributing with iron as an oxidant element.

Table 1. Chemical composition of ore sample (%).

| Total Cu | Soluble Cu | Fe | S     | Mn | Si   | Ca   | Cl  |
|----------|------------|----|-------|----|------|------|-----|
| 0.44     | 0.24       | 5.49| 2.46  | 0.05| 20.71| 2.79 | 0.18|

Table 2. Mineral characterization in the ore sample.

| Mineral  | Formula       | Composition (%) | Cu Distribution (%) |
|----------|---------------|-----------------|---------------------|
| Atacamite| Cu₂Cl(OH)₃    | 0.37            | 0.24                |
| Chalcopyrite| CuFe₂         | 0.18            | 0.06                |
| Chalcocite| Cu₂S          | 0.13            | 0.10                |
| Covellite| CuS           | 0.05            | 0.03                |
| Bornite  | Cu₂FeS₄       | 0.01            | <0.01               |
| Hematite | Fe₂O₃         | 1.21            |                     |
| Pyrite   | FeS₂          | 1.12            |                     |
| Limonite | FeOOH         | 0.17            |                     |
| Magnetite| Fe₃O₄         | 0.05            |                     |
| Gangue   |               | 96.71           |                     |
| Total    |               | 100             | 0.44                |

A set of tests was designed to identify the best conditions in pretreatment and leaching of the described ore. Variables in the composition of reagents such as NaCl, Fe₂(SO₄)₃, FeSO₄, H₂SO₄, and curing time were studied. Figure 1 shows the experimental procedure, including the evaluation stages.

2.1. Pretreatment Tests

To evaluate the variables described previously, eight samples of 500 g and size below 3/8” were used. First, the samples were placed on a plastic carpet. Then, solid NaCl is added to the ore sample, and it is homogenized. Next, the acid is added using a pipette; then, water is sprayed, and finally, the ore sample is homogenized. When iron salts are added, the process is similar. First, solid NaCl and iron salts are added to the ore sample, and then acid and water are added.
2.1. Pretreatment Tests

To evaluate the variables described previously, eight samples of 500 g and size below 3/8 ″ were used. First, the samples were placed on a plastic carpet. Then, solid NaCl is added to the ore sample, and it is homogenized. Next, the acid is added using a pipette; then, water is sprayed, and finally, the ore sample is homogenized. When iron salts are added, the process is similar. First, solid NaCl and iron salts are added to the ore sample, and then acid and water are added.

In tests, the acid dosage is defined as 75% and 100% of the ore acid consumption. The ore is mixed with the defined acid and solid NaCl concentration; then, the humidity is adjusted to 6% with seawater. After the curing time, the ore is washed at 90 °C in flasks at 910 rpm for 2 h. Finally, the solid residue is dried at 60 °C and analyzed by AAS to quantify the remained copper. The first stage of pretreatment, test A, examined the effect of NaCl, H₂SO₄, and curing time on the copper extraction; see Table 3. For all experiments, the copper extraction is determined.

Table 3. Pretreatment tests A.

| Test | H₂SO₄ (kg/t) | NaCl (kg/t) | Curing Time (d) |
|------|-------------|-------------|-----------------|
| A1   | 25          | 20          | 15              |
| A2   | 25          | 20          | 30              |
| A3   | 25          | 50          | 15              |
| A4   | 25          | 50          | 30              |
| A5   | 17          | 20          | 15              |
| A6   | 17          | 20          | 30              |
| A7   | 17          | 50          | 15              |
| A8   | 17          | 50          | 30              |

After the best condition of H₂SO₄ and NaCl dosage and curing time is found, a new set of pretreatment tests is performed. The effect of ferric and ferrous ions is analyzed using Fe₂(SO₄)₃·9.2H₂O and FeSO₄·7H₂O on a 25 kg/t dosage. The reagent dosage procedure of test B4 differed from the other test in the set. In this test, the solid NaCl is added together with the acid and the ore. Once the curing period of seven days is completed, the ore humidity is adjusted to 6% with seawater, and then the curing continues for 30 days in total. Table 4 shows the set of experiments B. All tests were carried out for 30 days of curing time.
Table 4. Pretreatment tests B.

| Test | H$_2$SO$_4$ (kg/t) | NaCl (kg/t) | Fe$_2$(SO$_4$)$_3$·9H$_2$O (kg/t) | FeSO$_4$·7H$_2$O (kg/t) |
|------|------------------|-------------|---------------------------------|------------------------|
| B1   | 25               | 50          | -                               | -                      |
| B2   | 25               | 50          | 25                              | -                      |
| B3   | 25               | 50          | -                               | 25                     |
| B4   | *                | -           | -                               | -                      |

* This test considers different procedure of reagents addition in the pretreatment stage.

2.2. Pretreatment-Leaching Tests

Using the best conditions found in tests A and B as a precedent, a new set of tests was designed to evaluate the pretreatment and leaching as an integrated process. The pretreatment contemplated in tests C is the same considered in tests B. The pretreatment in tests D kept the dosage of NaCl constant but evaluated less acid and less curing time due to the previous stage results. After curing the ore, column leaching tests were implemented in columns of 9.5 cm diameter and 40 cm high. The irrigation was an on–off 12 h cycle. The leaching rate was set to 8 L/h m$^2$ without recycling. The variables such as mass flow rate, pH, and oxidation-reduction potential (ORP) (Hanna portable pH/ORP meter, model HI991003, accuracy ± 0.02 pH y ± 2 mV, Ag/AgCl reference electrode) were controlled when samples were taken. Samples of drainage solutions were obtained to determine the total copper and acid concentration by AAS. The samples were taken every day for the first nine days, then every two days, and finally every four days to complete the 30 days.

After the leaching cycle is completed, every column is drained for two days, and then, the washed ore is dried at 60 °C. The first set of leaching experiments, called tests C, studied the effect of ferric and ferrous ions in the leaching solution, as shown in Figure 1. The experimental conditions are shown in Table 5. The reagent dosage in tests C4 and C5 is the same, differing in the addition procedure. The test C4 considers the NaCl addition with the sulfuric acid with a consecutive ore repose for seven days. Once the resting time is reached, water is added until the humidity reached 6%. After that, the ore pretreatment was carried out according to the optimal conditions founded in Tests B. Additionally, we analyzed the effect of ferric and ferrous salts. The composition of the leaching solution considered 10 g/L of H$_2$SO$_4$, 80 g/L of chloride (e.g., 20 g/L from seawater and 60 g/L from additional NaCl), and 0.5 g/L of Cu$^{2+}$ according to results found in [54]; see Table 5.

Table 5. Experimental conditions of pretreatment (25 kg/t H$_2$SO$_4$, 50 kg/t NaCl, humidity 6%, 30 d of curing time) and leaching (0.5 g/L Cu$^{2+}$, 80 g/L Cl$^-$, 10 g/L H$_2$SO$_4$), tests C.

| Test | Pretreatment | Leaching | ORP Initial (mV vs. SHE) |
|------|--------------|----------|--------------------------|
|      | Fe$_2$(SO$_4$)$_3$·9H$_2$O (kg/t) | FeSO$_4$·7H$_2$O (kg/t) | Fe$^{2+}$ (g/L) | Fe$^{3+}$ (g/L) | pH Initial | 0.40 | 803 |
| C1   | -            | -        | -                        | -            | 2             | 0.67 | 803 |
| C2   | 25           | -        | -                        | 2            | -             | 0.65 | 589 |
| C3   | -            | -        | 2                        | 2            | -             | 0.65 | 589 |
| C4   | -            | -        | 2                        | 2            | -             | 0.65 | 589 |
| C5   | -            | -        | 2                        | 2            | -             | 0.65 | 589 |
| C6   | -            | -        | -                        | -            | -             | 0.40 | 654 |

* This test considers different procedure of reagents addition in the pretreatment stage.

The second set of experiments, called tests D, studied the decreasing effect of the acid concentration and curing days on pretreatment. There is no addition of NaCl to the leaching solution, and the chloride content is due to seawater use. These tests aim to optimize the pretreatment conditions from the previous tests C. The leaching solutions for all tests was the same: 0.5 g/L Cu$^{2+}$, 20 g/L Cl$^-$ (provide for seawater), 10 g/L H$_2$SO$_4$, 2 g/L Fe$^{2+}$, and leaching time of 10 days (initial pH and ORP, 0.7 and 588.7 mV, respectively). The experimental conditions are shown in Table 6.
Table 6. Experimental conditions of pretreatment (50 kg/t NaCl, 6% humidity) tests D.

| Test | H$_2$SO$_4$ (kg/t) | Pretreatment Time (d) |
|------|------------------|---------------------|
| D1   | 10               | 1                   |
| D2   | 25               | 1                   |
| D3   | 10               | 15                  |
| D4   | 25               | 15                  |
| D5   | 25               | 30                  |

3. Results and Discussion

3.1. Pretreatment Test Results

From the first set of tests A, it can be noticed that the best extraction was found in test A4. This test included 25 kg/t ore of H$_2$SO$_4$, 50 kg/t ore of NaCl, and 30 days of curing, obtaining 62.8% of copper extraction. The lowest extraction of 42.7% was obtained in tests A5. This test considered only 17 kg/t ore of H$_2$SO$_4$, 20 kg/t ore of NaCl, and 15 days of pretreatment; see Figure 2.

Figure 2. Evaluation of pretreatment conditions in tests A expressed in copper extraction.

Figure 3 shows the main effect of the variables to evaluate the impact of the reagents and curing time on the extraction. The main effect plot represents the mean extraction at each level of the analyzed variables (i.e., sulfuric acid, sodium chloride, and curing time). The addition of sodium chloride and curing days significantly impacted the pretreatment, increasing the copper extraction by 17% approximately in both cases. On the other hand, the acid dose had a minimal effect, improving the extraction by only 3%.

After the optimal conditions are found in the first stage of pretreatment tests, the best conditions are implemented in the second stage of tests, called tests B. The results are shown in Figure 4. Adding FeSO$_4$·7H$_2$O into the pretreatment increased the extraction by 8% compared to test A4 (without iron salt). Less effect can be found adding Fe$_2$(SO$_4$)$_3$·9H$_2$O, increasing the extraction by 4.8%.
The copper extraction was 80.2%, and the asymptote was reached after 15 days of leaching. On the other hand, the lowest extraction was obtained in column C6. The pretreatment stage in these columns considered acid and chloride salt but no iron salts. In the leaching stage, the reagents added were the same as in column C4 except for the ferrous salt in column C6. This condition reduced the extraction to 75.5% approximately.

Figure 5 shows the extractions obtained for all columns. After 30 days of pretreatment at optimal conditions defined previously, the maximum is obtained in column C4. The copper extraction was 80.2%, and the asymptote was reached after 15 days of leaching. On the other hand, the lowest extraction was obtained in column C6. The pretreatment stage in these columns considered acid and chloride salt but no iron salts. In the leaching stage, the reagents added were the same as in column C4 except for the ferrous salt in column C6. This condition reduced the extraction to 75.5% approximately.

Test C6 considered no addition of ferric and ferrous salts either in the pretreatment or leaching stage, maintaining the ORP above the 680 mV SHE. The addition of ferrous ions into the leaching solution (i.e., columns C2 to C5) held the potential below 660 mV SHE on average, and the addition of ferric ions to C1 in a concentration of 2 g/L increases the ORP above 700 mV SHE in average. The effect of ferric or ferrous salts in the pretreatment (columns C2 and C3) is negligible at the defined concentrations. The best extractions are obtained at moderated ORP values, around 650 mV SHE on average. The pregnant leach solution (PLS) copper composition varies from 2.29 g/L in column C6 to 20 g/L in column C4; on the other hand, the iron composition varies from 25.07 g/L in column C6 to maximum values of 86.8 g/L (column C3) and 79.4 g/L (column C2). These latter columns correspond to tests that included iron salts in the pretreatment.
As mentioned previously, the ore composition is a mixed ore with Atacamite as the main oxide species and Chalcocite, Covelline, and Chalcopyrite as the main copper sulfide species. Due to the heterogeneity of the ore, it is difficult to compare the results with the literature. Articles related to the relation between potential and extraction are focused mainly on primary and secondary copper ores separately.

The mineralogy analysis from the residues showed that the Atacamite is leached completely. Concerning the sulfide species, the chalcocite was also not detected in the residues. The covellite composition remained constant, which was probably due to the transformation of chalcocite to covellite, according to Reaction (1). In addition, the chalcopyrite composition remained constant.

Figure 6 shows the acid consumption per unit of extracted copper of each column. Test C5 had the highest acid consumption with a high rate of 0.63 kg/t Cu, which is equivalent to 48 kg/t ore.
Furthermore, to the study of the effect of iron salts on the pretreatment and leaching stages, the second set of experiments was performed to evaluate new conditions of acid and time on curing (Table 6) to optimize cycles and acid consumption. Table 7 shows the results from tests D (operational conditions are shown in Table 6). We noticed a slight effect on the copper extraction while the acid concentration in curing varies. On the other hand, changing the curing time from 1 to 15 days can increase the copper extraction by 10 percentage points. In addition, when increasing curing days to double, the extraction increases only 3 percentage points. All experiences shown in Table 7 considered 10 days of leaching after curing. Figure 7 shows the total acid consumption per unit of extracted copper. The lowest acid consumption per unit of copper extracted is obtained in test D3 with 0.32 kg/t Cu. The ORP varied from 620 to 650 mV on average approximately. The highest ORP was found in the test with the best copper extraction.

Table 7. Extraction in percentage for tests D.

| Test | Extraction (%) |
|------|----------------|
| D1   | 53.71          |
| D2   | 54.87          |
| D3   | 62.60          |
| D4   | 63.94          |
| D5   | 66.46          |

Figure 7. Total acid consumption in kg/t Cu for all columns in tests D.

4. Column Leaching Modeling

To represent the behavior of the leaching kinetics in the studied conditions, it is implemented the model proposed by Mellado et al. [50,55]. The copper extraction in column $E$ is represented in a negative exponential curve characterized by an asymptotic limit, which is defined by the maximal copper extraction $E_\infty$; a kinetic parameter $K$ is defined and shown in Equation (5)

$$E = \frac{\alpha}{Z^\gamma + \beta} \left[ 1 - \lambda e^{K_{\theta}(t-\omega^*)} - (1 - \lambda)e^{K_r(t-\omega^*)} \right]$$  (5)
where \( Z \) is the column height, \( \alpha, \beta, \gamma, \) and \( \lambda \) are fitted parameters, and \( t \) is time. The parameters \( K_\theta, K_\nu, \) and \( \omega^* \) are defined as

\[
K_\theta = k_\theta \frac{\mu_s}{\epsilon_0 Z} \tag{6}
\]

\[
K_\nu = k_\tau \frac{D_{Ae}}{\epsilon_0 r^2} \tag{7}
\]

\[
\omega^* = t_0 \frac{\epsilon_1 Z}{\mu_s} \tag{8}
\]

The parameters \( k_\theta \) and \( k_\tau \) are kinetic parameters, \( t_0 \) is the delay time in reaction, \( \epsilon_0 \) is the particle porosity, \( r \) is the particle size, \( \epsilon_1 \) is the volumetric fraction of the solution of the bulk, \( \mu_s \) is the superficial velocity, and \( D_{Ae} \) is the effective diffusivity of the pore of the reagent. Due to the performed experiences, the bulk and leaching current properties remained constant; therefore, Equation (5) can be simplified to Equation (9).

\[
E = E_\infty \left[ 1 - \lambda e^{-K_\theta (t-t_0)} - (1 - \lambda) e^{-K_\nu (t-t_0)} \right] \tag{9}
\]

The curing stage before leaching is included as an initial copper extraction \( E_0 \) at a time \( t_0 \) modifying Equation (9) to Equation (10).

\[
E = E_0 + (E_\infty - E_0) \left[ 1 - \lambda e^{-K_\theta (t-t_0)} - (1 - \lambda) e^{-K_\nu (t-t_0)} \right] \tag{10}
\]

The total copper extraction is contributed by the extraction of every copper mineral species. Equation (11) includes the extraction of all mineral species leached, according to the data from Table 8.

\[
E = \sum_{i=1}^{2} \left\{ E_{0i} + (E_{\infty i} - E_{0i}) \left[ 1 - \lambda_i e^{-K_\theta (t-t_0)} - (1 - \lambda_i) e^{-K_\nu (t-t_0)} \right] \right\} \tag{11}
\]

Table 8. Kinetic parameters adjusted from tests C.

| Column | Atacamite | Chalcocite |
|--------|-----------|------------|
|        | \( E_0 \) | \( \lambda \) | \( K_\theta \) | \( K_\nu \) | \( E_\infty \) | \( E_0 \) | \( \lambda \) | \( K_\theta \) | \( K_\nu \) | \( E_\infty \) |
| C1     | 36.91     | 0.9218     | 0.3796     | 0.5373     | 54.70     | 15.38     | 0.9532     | 0.3796     | 0.2088     | 22.79 |
| C2     | 39.16     | 0.9458     | 0.3177     | 0.5380     | 55.27     | 16.32     | 0.9458     | 0.3177     | 0.3580     | 23.03 |
| C3     | 41.99     | 0.9198     | 0.3065     | 0.3247     | 55.87     | 17.50     | 0.9421     | 0.3164     | 0.1625     | 23.28 |
| C4     | 35.44     | 0.9288     | 0.3478     | 0.1090     | 56.62     | 14.77     | 0.9469     | 0.2379     | 0.1281     | 23.59 |
| C5     | 34.80     | 0.9154     | 0.4602     | 0.0326     | 53.47     | 14.50     | 0.9487     | 0.3490     | 0.0567     | 22.28 |
| C6     | 37.27     | 0.9154     | 0.3715     | 0.1487     | 53.34     | 15.53     | 0.9472     | 0.3032     | 0.0106     | 22.22 |
| \( \sigma \) | 2.638 | 0.012 | 0.055 | 0.1880 | 1.31 | 1.10 | 0.0040 | 0.0480 | 0.1230 | 0.546 |
| CV (%) | 7.017 | 1.249 | 15.185 | 74.783 | 2.38 | 7.02 | 0.3840 | 15.042 | 79.677 | 2.387 |

Subindex \( i \) represents each mineralogical species.

Table 8 shows the adjusted parameter for Equation (11). The methodology used for model fitting was the Generalized Reduced Gradient algorithm (GRG) for nonlinear problems. The data represent the first 15 days of leaching until the asymptote was reached.

Figure 8 shows the copper extractions from tests (black dots), the extractions of the developed model for the total copper extraction (black lines), Atacamite (dark gray lines), and Chalcocite (light gray lines). Figure 9 showed the sum of the squared residuals (SSE) and the standard deviation of the distance between the data values and the fitted values (S) for each column. It can be noticed that the model adequately represents the extraction of the column leaching process. The extraction calculated from the model has a deviation of less than three percentage points from the experimental data.
Figure 8. Comparison between experimental copper extraction and model adjustment for columns of tests C. (a) Test C1. (b) Test C2. (c) Test C3. (d) Test C4. (e) Test C5. (f) Test C6.
On the other hand, Table 8 shows the standard deviation (σ) and the coefficient of variation (CV) of each adjusted parameter. All parameters that exhibited low dispersion can be interpreted as invariant parameters to the variability of the pretreatment and leaching conditions except $K_{r_r}$, which exhibits a CV near 80%.

The high value of the weight of kinetic factor $λ$ indicates that the kinetic is controlled by the first term of the expression involving the constant $K_0$. Therefore, the kinetic expression can be simplified to Equation (12). The statistical analysis of this model also showed extremely low values of $S$ and SSE, exhibiting a good approach.

$$E = \sum_{i=1}^{2} \left( E_{0i} + (E_{0i} - E_{0i}) \left[ 1 - \lambda_i e^{-K_{0i}(t-t_0)} \right] \right)$$  \hspace{1cm} (12)

5. Conclusions

The leaching of a copper mixed ore composed of Atacamite, Chalcopyrite, Covellite, and Chalcocite, including pretreatment stage and consecutive leaching stage with different oxidants and reductants, is studied. The main conclusions are the following:

1. The first stage of pretreatment tests showed a maximal copper extraction of 62.5% with 25 kg/t of acid, 50 kg/t of NaCl, and 30 days of curing. The pretreatment can be improved by incorporating ferrous salts in the curing, increasing the extraction to 67.9%. The main effect plot showed that the concentration of NaCl and curing time could significantly affect the efficiency of the curing process.

2. The second stage of tests showed that the maximal extraction of 80.2% is obtained by adding 25 kg/t of acid, 50 kg/t of NaCl, and 25 kg/t of FeSO$_4$·7H$_2$O in the pretreatment and 0.5 g/L of Cu$^{2+}$, 80 g/L of Cl$^-$, 10 g/L of H$_2$SO$_4$, and 2 g/L of Fe$^{2+}$ in the leaching solution. At these conditions, the ORP remained below the 650 mV SHE on average. The acid consumption was 0.55 kg acid/t Cu.

3. From tests D, we found that a decrease in the chloride content in the leaching solution from 80 to 20 g/L (content in seawater) decrease the copper extraction from 79 to 66.5% (considering ten days of leaching both cases). Additionally, the analysis showed that a decrease in the acid concentration in pretreatment does not mostly affect copper extraction.

Figure 9. The goodness of fit for each column (test C) modeled, represented in sum of the squared residuals (SSE) (gray columns) and standard deviation of the distance between the data values and the fitted values ($S$ indexes) (light gray line).
extractions. Conversely, the curing time could affect the extraction on values below 15 days.

4. The analytic kinetic model implemented showed acceptable values of SSE and S, demonstrating the goodness of fit. It was concluded that the kinetics constant $K_a$ presents low variability with pretreatment and leaching at the evaluated leaching conditions.
