Abstract. We give a rigorous proof of the validity of the point vortex description for a class of inviscid generalized surface quasi-geostrophic models on the whole plane.

1. Introduction. The main aim of the paper is to give a rigorous proof of the validity of the point vortex description for a class of inviscid generalized surface quasi-geostrophic (briefly, gSQG) models. This extends the connections, well known in the case of Euler equations [29, 30], between the point vortex theory and these models.

We deal with the following class of problems on $\mathbb{R}^2$,

\[
\begin{cases}
\partial_t \theta + u \cdot \nabla \theta = 0, \\
(-\Delta)^m \psi = \theta, \\
u = \nabla^\perp \psi.
\end{cases}
\] (1.1)

The case $m = 2$ corresponds to the Euler equations, the case $m = 1$ corresponds to the inviscid surface quasi-geostrophic equations (SQG). In meteorology the inviscid SQG has been derived to model the production of fronts due to the tightening of temperature gradients, see [12, 23, 22], see also [14, 32] for the first mathematical and geophysical studies on the subject. The generalized version of the model examined in this paper bridges the cases of Euler and SQG and shares a series of common physical features namely the emergence of inverse cascades [35, 36, 37, 38], as well as deeper universal invariance properties [2, 3, 18]. In this paper we will consider the cases $m \in (1, 2)$.

From the mathematical point of view the generalized models share the same difficulties of SQG. Local existence and uniqueness holds for smooth enough initial data, see for instance [8]. It is not known if the generalized SQG, including the case $m = 1$, has a global solution. There is numerical evidence [15] of emergence of singularities in the generalized SQG, for $m \in [1, 2)$, as well as global stable solutions [16]. Regularity criteria are known, see [9]. Weak solutions are known for SQG in $L^2$ [31] and $L^p$, with $p > \frac{4}{3}$ [26], see [8] for weak solution in $L^2$ on the torus for $m < 1$. We will give our version of weak solutions in Section 2.

Point vortices for (1.1) represent profiles that are sharply concentrated around some points. Formally (1.1) is a transport equation, so we may believe that an initial profile given as the configuration of $N$ points,

$$\theta(0) = \sum_{j=1}^{N} \gamma_j \delta_{x_j},$$

where $\gamma_1, \gamma_2, \ldots, \gamma_N$, are given numbers (that we will call the intensities of the point vortices), evolves as a measure of the same kind, with constant intensities (a generalized version of the conservation of circulation) and where the positions evolve according to the system of equations

$$\begin{cases} \dot{X}_j = \sum_{k \neq j} \gamma_k \nabla^\perp G_m(X_j, X_k), \\ X_j(0) = x_j, \end{cases}$$

for $j = 1, 2, \ldots, N$, (1.3)

where $G_m$ is the Green function of the fractional Laplacian $(-\Delta)^{\frac{m}{2}}$ on $\mathbb{R}^2$,

$$G_m(x, y) = G_m(x - y) = \frac{\Gamma\left(\frac{2-m}{2}\right)}{2^{m/2} \pi^{\frac{m}{2}} |\Gamma\left(\frac{m}{2}\right)| |x - y|^{m-2}},$$

(1.4)

In our first main result (Theorem 3.1) we prove that the above system (1.3) has, for fixed $N$, a global solution for a.e. initial condition, under a generic (and necessary) assumption on the intensities.

Additionally, in our second main result (Theorem 3.2) we prove that point vortices provide an approximation of solutions to (1.1), namely if an initial condition is approximated, in the sense of measures, by point vortices (1.2) as $N \uparrow \infty$, then solutions to (1.1) are approximated, again in the sense of measures, by the evolution of the point vortex measure

$$\sum_{j=1}^{N} \gamma_j \delta_{X_j(t)}.$$ 

Unfortunately, again due to the singularity of the kernel $\nabla^\perp G_m$, the evolution of vortices corresponds to a regularization of the original dynamics. The regularized kernel converges though to the original kernel as $N \uparrow \infty$ (see Remark 3.5 for additional considerations).

For measure valued solution, one should interpret (1.1) in the sense of distributions. But, as in the case of Euler equations ($m = 2$), this is not enough to include measures with atoms. In the case of Euler equations a symmetrisation [17] (see also [33, 34]) allows to tame the singularity of the Biot-Savart kernel. In this context, writing the equation against a test function $\varphi$ only in terms of $\theta$ yields

$$\int \int \theta(t, x) \varphi(t, x) \, dx \, dt + \int \int k_m(x - y) \cdot (\nabla \varphi(t, x) - \nabla \varphi(t, y)) \theta(t, x) \theta(t, y) \, dx \, dy \, dt = 0,$$
where \( k_m = \nabla^\perp G_m \). Unfortunately, in this more singular setting, the new kernel \( k_m(x - y) \cdot (\nabla \varphi(t, x) - \nabla \varphi(t, y)) \) is not bounded on the diagonal, and there is no hope to give a meaning to solutions to (1.1) with point masses. Nevertheless, in our third main result (Theorem 3.6) we are able to prove that for values of the parameter \( m \) not too small \((\sqrt{3} < m < 2)\), a sequence of vortex blobs solutions to (1.1) converges, as the size of the blobs goes to 0, to the configuration of point masses that obeys to (1.3).

The intuitive reason, valid for Euler [30] but crucial in this setting, is that a single vortex does not move subject to the self-generated velocity field, but only according to the velocity field generated by all other vortices. The singular self-interaction, absent in (1.3), does not play a role, although it should due to singularity of the kernel \( k_m \), at the level of the equation. In rigorous terms, we prove localisation of vortices (Proposition 3.8), namely, if \( \theta \) is initially a vortex blob, then it remains a vortex blob of comparable size. Our proof of localisation fails when \( m \leq \sqrt{3} \), but it may be a technical issue of the method used and it is not clear if the main theorem about convergence of vortex blobs to point vortices fails.

We conclude with a few additional comments. The first is that the extension of these results to the torus is straightforward, due to the absence of boundaries. In the presence of boundaries the problem is more delicate. We wish also to emphasise the possible connection with the evolution of vortex patches, namely solutions that take only two values, and where the main interest is about the evolution of the interface. See for instance [8, 24, 16] for relevant results. Finally we remark that the validation of the point vortex motion proved here bolsters the statistical mechanics of point vortices discussed in [20], where the authors extend results on Euler equations from [5, 6, 25, 4].

Upon completion of the paper, after submission to arXiv, we have been pointed out paper [7], that roughly contains similar results. In general our approach is rigorous, contains full and, we believe, correct statements and proofs, deals with the not so obvious problem of existence of solutions of (1.1), and therefore includes accurate statements related to the precise notion of solutions.

**Contents.** The paper is organized as follows. In Section 2 we prove existence of weak solutions with initial conditions in \( L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2) \) (Theorem 2.6), since this is the class for vortex blobs. In principle, following [26], one could do better. For instance, if \( \theta \in L^p(\mathbb{R}^2) \) and \( p < \frac{2}{m-1} \), by the Hardy-Littlewood-Sobolev inequality \( u = k_m * \theta \in L^q(\mathbb{R}^2) \) with \( \frac{1}{q} = \frac{1}{p} - \frac{1}{2} (m - 1) \) and \( \theta u \in L^r(\mathbb{R}^2) \) for some \( r \) if \( p \geq 4m + 1 \). The assumption \( L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2) \) for the initial condition greatly simplifies the existence theorem. We point out though that, using probabilistic techniques, [19] are able to solve the equation with initial conditions in a space of much rougher functions.

In Section 3 we prove that under suitable generic assumptions on the intensities, the point vortex motion (1.3) has a global non-colliding solution for a.e. initial condition (Theorem 3.1). The approximation of solutions of (1.1) is proved in Theorem 3.2. With a well defined motion at hand, we are finally able to prove the main result about convergence of vortex blobs to the point vortex motion (Theorem 3.6) using localisation (Proposition 3.8).

**Notations.** First of all, we will name pseudo-vorticity the term \( \theta \) in (1.1), in analogy with the Euler case \( m = 2 \), even though this may be inappropriate for instance in the context of SQG, where \( \theta \) is a temperature.
We will denote by $B_r(x)$ the ball centred at $x$ with radius $r$, by $\delta_x$ the measure concentrated at a point $x \in \mathbb{R}^2$, by $\ast$ the convolution product, by $\nabla^\perp$ the vector $\nabla^\perp = (-\partial x_2, \partial x_1)$. We will denote by $\|\cdot\|_{L^p}$ the norm of the Lebesgue space $L^p(\mathbb{R}^2)$, $1 \leq p \leq \infty$ and we will sometime use also the local version $L^p_{loc}(\mathbb{R}^2)$ of all functions whose $p^{th}$ norm is integrable over all bounded set. We recall that $G_m$ is the Green’s function of the fractional Laplacian, see (1.4), and $k_m = \nabla^\perp G_m$ here plays the role of the Biot-Savart kernel. Finally we shall use the symbol $\lesssim$ for inequalities up to some constant that does not depend on the main parameters of the problem, and thus ultimately does not matter.

2. Existence of weak solutions. In this section we prove existence of weak solutions for (1.1) with initial condition in $L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2)$. To this end we recast problem (1.1) as

$$
\begin{aligned}
\partial_t \theta + \nabla \cdot (u \theta) &= 0, \\
u &= k_m \ast \theta,
\end{aligned}
$$

(2.1)

where $k_m = \nabla^\perp G_m$ and $G_m$ is the Green function for the fractional Laplacian $(-\Delta)^{\frac{m}{2}}$ given in (1.4).

**Definition 2.1** (Weak solution). Given $\theta_0 \in L^1_{loc}(\mathbb{R}^2)$, a solution to (2.1) is a distribution such that for all $t > 0$ and $\varphi \in C_c^\infty(\mathbb{R}^2)$,

$$
\int_{\mathbb{R}^2} (\theta(t,x) - \theta_0(x)) \varphi(x) \, dx - \int_0^t \int_{\mathbb{R}^2} \theta(s,x) u(s,x) \cdot \nabla \varphi(s,x) \, dx \, ds = 0,
$$

where $u = k_m \ast \theta$.

For a function $f : \mathbb{R}^2 \to \mathbb{R}$, define its *centre of pseudo-vorticity* as

$$
C_f := \int_{\mathbb{R}^2} x f(x) \, dx,
$$

(2.2)

whenever the integral is well defined, and its *moment of inertia*

$$
J_f := \int_{\mathbb{R}^2} |x - c_f|^2 |f(x)|^2 \, dx.
$$

(2.3)

The proof of existence of weak solutions of (2.1) proceeds through a vanishing viscosity approximation. We will actually make a two-steps approximation to prove some conservation properties that will turn out to be crucial for the proof of Theorem 3.6. We start by stating a classical inequality about the velocity $u = k_m \ast \theta$, that will be useful for our purposes.

**Lemma 2.2.** Let $m \in (1,2)$. Then

$$
\|k_m \ast f\|_{L^q} \lesssim \|f\|_{L^p} \lesssim \|f\|_{L^2}^{\frac{1}{2} + \frac{1}{4}(m-1)} \|f\|_{L^\infty}^{\frac{1}{4}(3-m) - \frac{1}{4}}.
$$

where $q > \frac{2}{m}$ and $\frac{1}{p} - \frac{1}{q} = \frac{1}{2} (m - 1)$.

Moreover there is $c = c(\|f\|_{L^1}, \|f\|_{L^\infty})$ such that for all $x, y \in \mathbb{R}^2$,

$$
|k_m \ast f(x) - k_m \ast f(y)| \leq c (1 \wedge |x - y|)^{m-1}.
$$

To prove the existence of weak solutions to (2.1) (see Theorem 2.6), we will suitably regularize the initial condition and the velocity. To this end, let $\rho \in C_c^\infty(\mathbb{R}^2)$ be symmetric, $0 \leq \rho \leq 1$, and $\int_{\mathbb{R}^2} \rho(x) \, dx = 1$, and set $\rho_\epsilon = \epsilon^{-2} \rho(x/\epsilon)$. Denote by $k_m^\epsilon$ the kernel $k_m^\epsilon = \rho_\epsilon \ast k_m$, and, for $\theta_0 \in L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2)$, set $\theta_0^\epsilon = \rho_\epsilon \ast \theta_0$. 
2.1. The viscous approximation. Given $\epsilon > 0$ and $\nu > 0$, consider the problem

$$
\begin{cases}
\partial_t \theta + \nabla \cdot (u\theta) = \nu \Delta \theta, \\
u = k_m^\epsilon \ast \theta.
\end{cases}
$$

(2.4)

**Proposition 2.3.** Given $\theta_0 \in L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2)$ and $\epsilon > 0$, $\nu > 0$, there is a unique classical solution $\theta_{\epsilon, \nu}$ of (2.4) with initial condition $\theta_0$. Moreover, for every $n \geq 0$, every $p \in [1, \infty)$ and every $T > 0$, there is a number $c = c(\epsilon, \nu, n, p, T, \theta_0)$ such that

$$
sup_{[0, T]} \|D^n \theta_{\epsilon, \nu}\|_{L^p} \leq c,
$$

(2.5)

for all multi-indices $\alpha$ with $|\alpha| = n$. In particular, for all $t > 0$ and all $p \in [1, \infty)$,

$$
\|\theta_{\epsilon, \nu}\|_{L^p} \leq \|\theta_0\|_{L^p}.
$$

(2.6)

**Proof.** We give a sketch of the proof, and for simplicity we drop the subscript $_{\epsilon, \nu}$. Existence of a solution is standard, see for instance [11, 10]. We first show the conservation in $L^p$, $1 \leq p < \infty$,

$$
\frac{d}{dt} \int_{\mathbb{R}^2} |\theta(t, x)|^p \, dx = p \int_{\mathbb{R}^2} |\theta|^{p-1} \text{sgn}(\theta)(\nu \Delta \theta - \nabla \cdot (u\theta)) \, dx
$$

$$
= p\nu \int_{\mathbb{R}^2} |\theta|^{p-1} \text{sgn}(\theta) \Delta \theta \, dx - p \int_{\mathbb{R}^2} u \cdot \nabla |\theta|^p \, dx.
$$

The first integral on the right hand side is non-positive, see [11, 13], the second integral is zero by integration by parts, since $\nabla \cdot u = 0$, and this proves that the derivative is non-positive. The case $p = \infty$ follows in the limit $p \uparrow \infty$.

Likewise, if $\eta = D^\alpha \theta$, then $\eta$ solves

$$
\partial_t \eta + \nabla \cdot (u\eta) - \nu \Delta \eta = (\partial_{x_1} u) \cdot \nabla D^{\alpha-1,0} \theta + (\partial_{x_2} u) \cdot \nabla D^{\alpha-0,1} \theta + F,
$$

where $F$ is bilinear in the derivatives of order at most $n$ of $u$ and of order at most $n-1$ of $\theta$. Since by Lemma 2.2, for every multi-index $\beta$, $\|D^\beta u\|_{L^\infty} \leq c(\epsilon, \beta)k_m^\epsilon \ast \theta \leq c(m, \epsilon, \theta_0)$, we have that

$$
\frac{d}{dt} \int_{\mathbb{R}^2} \sum_{|\alpha| = n} |D^\alpha \theta|^p \, dx \leq (1 + c(m, \epsilon, \theta_0)) \int_{\mathbb{R}^2} \sum_{|\alpha| = n} |D^\alpha \theta|^p \, dx + \|F\|_{L^p}
$$

The bound follows by an induction argument to estimate $\|F\|_{L^p}$ in terms of lower order derivatives of $\theta$, and Gronwall’s lemma.

To prove uniqueness, let $\theta_1, u_1$ and $\theta_2, u_2$ solutions to (2.4) with the same initial condition $\theta_0$, and set $\delta = \theta_1 - \theta_2$, $\gamma = u_1 - u_2$. Then

$$
\partial_t \delta + \nabla \cdot (u_1 \delta + \gamma \theta_2) = \nu \Delta \delta,
$$

therefore

$$
\frac{d}{dt} \int_{\mathbb{R}^2} \delta^2 \, dx = -\int_{\mathbb{R}^2} u_1 \cdot \nabla \delta^2 \, dx - 2 \int_{\mathbb{R}^2} \delta \gamma \nabla \theta_2 \, dx - 2\nu \int_{\mathbb{R}^2} |\nabla \delta|^2 \, dx
$$

$$
\leq -2 \int_{\mathbb{R}^2} \delta \gamma \nabla \theta_2 \, dx.
$$

By the Hölder inequality and Lemma 2.2,

$$
\left| \int_{\mathbb{R}^2} \delta \gamma \nabla \theta_2 \, dx \right| \leq \|\delta\|_{L^{2m}} \|\gamma\|_{L^{\frac{2m}{m-2}}} \|\nabla \theta_2\|_{L^{\frac{2m}{m-2}}} \lesssim \|\nabla \theta_2\|_{L^{\frac{2m}{m-2}}} \|\delta\|_{L^2}^2.
$$

Uniqueness follows by the Gronwall lemma. \qed
2.2. The inviscid approximation. Given $\epsilon > 0$, consider the following inviscid problem with regularized velocity,

$$\begin{cases}
\partial_t \theta + \nabla \cdot (u \theta) = 0, \\
u = k^\epsilon \ast \theta.
\end{cases} \tag{2.7}$$

**Proposition 2.4.** Given $\theta_0 \in L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2)$ and $\epsilon > 0$, there is a unique classical solution $\theta_\epsilon$ of (2.7) with initial condition $\theta_0^\epsilon$. Moreover, for every $n \geq 0$, every $p \in (1, \infty)$ and every $T > 0$, there is a number $c = c(\epsilon, \nu, n, p, T, \theta_0)$ such that

$$\sup_{[0,T]} \| D^\alpha \theta_\epsilon \|_{L^p} \leq c, \tag{2.8}$$

for all multi-indices $\alpha$ with $|\alpha| = n$. In particular, for all $t > 0$ and all $p \in [1, \infty]$,

$$\| \theta_\epsilon \|_{L^p} \leq \| \theta_0 \|_{L^p}. \tag{2.9}$$

Finally, for all $t > 0$,

$$\int_{\mathbb{R}^2} \theta_\epsilon(t, x) \, dx = \int_{\mathbb{R}^2} \theta_0^\epsilon(x) \, dx, \tag{2.10}$$

and, if $\theta_0 \geq 0$, then $\theta_\epsilon(t, x) \geq 0$ for all $t > 0$.

**Proof.** In Proposition 2.3 we have seen that the sequence $(\theta_{\epsilon, \nu})_{\nu > 0}$ of solutions of (2.4) is bounded in $L^\infty(0, T; W^{k,p}(\mathbb{R}^2))$ for all $p > 1$, all $T > 0$ and all $k \geq 1$, and we wish to use this sequence to construct a solution of (2.7). By a diagonal argument there is a sequence $(\nu_n)_{n \geq 1}$ such that $(\theta_{\epsilon, \nu_n})_{n \geq 1}$ weak-* converges in $L^\infty(0, T; W^{k,p}(\mathbb{R}^2))$ to a function $\theta_\epsilon$, for every $T > 0$, $k \geq 1$ and $p > 1$. In particular, (2.8) and (2.9) (for $p > 1$) hold.

The convergence of $\theta_{\epsilon, \nu}$, as well as of its derivatives and of their respective equations, goes in an analogous, even simpler, way as in the proof of Theorem 2.6, where all details will be given, and is therefore omitted here. The argument for uniqueness is the same as in Proposition 2.3, since the viscous term is not used in the proof.

Finally, to prove conservation of mass and conservation of sign, consider for each $x \in \mathbb{R}^2$ and each $t > 0$ the backward system (of characteristics),

$$\begin{cases}
\frac{d}{ds} Y_t^{s,x} = u_\epsilon(s, Y_t^{s,x}), \\
Y_t^{s,x} = x. \tag{2.11}
\end{cases}$$

The solution is well defined and global since $u$ is continuous and globally Lipschitz in the space variable. It is standard to see that $x \mapsto Y_t^{s,x}$, with $0 \leq s \leq t$, are diffeomorphisms. Moreover, if $J(s, x)$ is the determinant of the Jacobian matrix of $x \mapsto Y_t^{s,x}$, then $J(t, x) = 1$ and

$$\dot{J}(s, x) = (\nabla \cdot u_\epsilon)(s, Y_t^{s,x})J(s, x),$$

therefore $J(s, x) = 1$ for all $s \in [0, t]$, since $u_\epsilon$ is divergence free. Finally, a simple computation shows that

$$\frac{d}{ds} \theta_\epsilon(s, Y_t^{s,x}) = 0.$$

These arguments, together with the simple remark that if $\theta_0 \geq 0$, then $\theta_0^\epsilon \geq 0$ (since the regularizing kernel is positive) prove conservation of mass and conservation of sign, as well as (2.9) for $p = 1$. \qed
The above existence and uniqueness result can be improved. Indeed, we can get rid of the regularization in the initial condition. To this end, denote by $|·|_*$ the (bounded) metric $|x−y|_*=1 \wedge |x−y|$, and let $W_1$ be the 1-Wasserstein distance on non-negative finite measures on $\mathbb{R}^2$. The Wasserstein distance can be extended to signed measure with equal positive and negative masses by $W_1(\mu,\nu) = W_1(\mu_+,\nu_+) + W_1(\mu_-,\nu_-)$. Since here $W_1$ is based on a bounded metric, convergence in $W_1$ is equivalent to the standard weak convergence of measures.

**Corollary 2.5.** Given a finite measure $\theta_0$ on $\mathbb{R}^2$, and $\epsilon > 0$, there is a unique solution $\theta$ on $[0, \infty)$ in the sense of distributions of (2.7).

Moreover, if $\theta^1_0, \theta^2_0$ are two different measures with the same positive and negative masses, then for all $T > 0$,

$$\sup_{t \in [0,T]} W_1(\theta_1(t), \theta_2(t)) \leq C(c_\epsilon, T) W_1(\theta^1_0, \theta^2_0),$$

(2.12)

where $\theta_1, \theta_2$ are solutions of (2.7) with respective initial conditions $\theta^1_0, \theta^2_0$, and $c_\epsilon = 2\|k_m^\epsilon\|_{L^\infty} \vee \|\nabla k_m^\epsilon\|_{L^\infty}$.

Finally, if $\theta_0 \in L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2)$, then

$$\|\theta(t)\|_{L^p} \leq \|\theta_0\|_{L^p},$$

for every $t \geq 0$ and $p \in [0, \infty]$.

**Proof.** The idea here is to consider in Proposition 2.4 above two regularization parameters: one for the velocity ($\epsilon$), and one for the initial condition. The $L^p$ conservation follows as in the previous Proposition 2.4. We prove here only (2.12), which in particular proves existence and uniqueness.

Let us notice first that if $\mu, \nu$ are measures, then

$$\|k_m^\epsilon * \mu - k_m^\epsilon * \nu\|_{L^\infty} \leq c_\epsilon W_1(\mu, \nu).$$

(2.13)

This is immediate since $k_m^\epsilon$ is Lipschitz with respect to $|·|_*$ with Lipschitz constant $c_\epsilon$, and by duality, for probability measures $\mu, \nu$,

$$W_1(\mu, \nu) = \sup \int_{\mathbb{R}^2} f(\mu - \nu),$$

where the supremum is taken over all $|·|_*$-Lipschitz function with Lipschitz constant 1.

Set $u_i = k_m^\epsilon \star \theta_i, i = 1, 2$. We claim that the following inequality holds,

$$W_1(\theta_1(t), \theta_2(t)) \leq e^{c_\epsilon t} W_1(\theta^1_0, \theta^2_0) + c_\epsilon e^{c_\epsilon t} \int_0^t W_1(\theta_1(s), \theta_2(s)) ds.$$  (2.14)

By Gronwall’s lemma, (2.12) then follows. We turn to the proof of (2.14). Let $\mathbb{P}$ be a coupling of $|\theta^1_0|, |\theta^2_0|$, then the measure $\mathbb{P}_t$, defined as

$$\int_{\mathbb{R}^2} \int_{\mathbb{R}^2} f(x,y) \mathbb{P}_t(dx, dy) = \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} f(X_1^t(x), X_2^t(y)) \mathbb{P}(dx, dy),$$
is a coupling of $|\theta_1(t)|, |\theta_2(t)|$, where $X^{t,x}_i, i = 1,2$ are the back-to-label maps of (2.11) corresponding to $u_1, u_2$. By (2.13) we have that
\[ |X^{t,x}_1(0) - X^{t,y}_2(0)| \leq |x-y| + \int_0^t |u_1(t-s, X^{t,x}_1(s)) - u_2(t-s, X^{t,y}_2(s))| ds \]
\[ \leq |x-y| + c_e \int_0^t |X^{t,x}_1(s) - X^{t,y}_2(s)| ds + c_c \int_0^t W_1(\theta_1(s), \theta_2(s)) ds. \]

The Gronwall lemma yields
\[ |X^{t,x}_1(0) - X^{t,y}_2(0)| \leq c^{c_t} |x-y| + c_c e^{c_t} \int_0^t W_1(\theta_1(s), \theta_2(s)) ds. \]

By integrating with $\mathbb{P}$ we have
\[ W_1(\theta_1(t), \theta_2(t)) \leq e^{c_t} \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} |x-y| \mathbb{P}(dx, dy) + c_c e^{c_t} \int_0^t W_1(\theta_1(s), \theta_2(s)) ds, \]
and taking the infimum over all $\mathbb{P}$ yields (2.14).

### 2.3. The inviscid problem

We first prove existence of a weak solution for problem (2.1).

**Theorem 2.6.** Let $\theta_0 \in L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2)$, then there is a solution $\theta$ of (2.1) on $[0, \infty)$ with initial condition $\theta_0$, in the sense of Definition 2.1. Moreover,
\[ \|\theta(t)\|_{L^p} \leq \|\theta_0\|_{L^p}, \quad (2.15) \]
for every $p \in [1, \infty]$ and all $t > 0$.

**Proof.** The family $(\theta_\epsilon)_{\epsilon > 0}$ of solutions to (2.7) is bounded in $L^\infty(0,T;L^p(\mathbb{R}^2))$ for all $p > 1$, and all $T > 0$. By a diagonal argument there is a sequence $(\epsilon_n)_{n \geq 1}$ such that $(\theta_{\epsilon_n})_{n \geq 1}$ weak-\*$^\ast$ converges in $L^\infty(0,T;L^p(\mathbb{R}^2))$ to a function $\theta$, for every $T > 0$ and $p > 1$. In the rest of the proof we will set $\theta_n = \theta_{\epsilon_n}, \rho_n = \rho_{\epsilon_n}, u_n = \rho_n \ast_{\mathbb{R}^2} \theta_n$, and $n = k_n \ast \theta$.

**Step 1.** strong convergence of $\theta_n$. Fix $\varphi \in C^\infty_c(\mathbb{R}^2)$. By the H"older inequality,
\[ \int_{\mathbb{R}^2} \varphi \partial_t \theta_n \, dx = \int_{\mathbb{R}^2} \theta_n u_n \cdot \nabla \varphi \, dx \leq ||\nabla \varphi||_{L^2} ||\theta_n||_{L^2} ||u_n||_{L^\infty} \leq c ||\nabla \varphi||_{L^2}. \]
Therefore $(\partial_t (\varphi \theta_n))_{n \geq 1}$ is bounded in $L^\infty(0,T;H^{-1}(\text{Supp} \, \varphi))$. Since $(\varphi \theta_n)_{n \geq 1}$ is bounded in $L^\infty(0,T;L^2(\text{Supp} \, \varphi))$, the Aubin-Lions lemma ensures that $(\varphi \theta_n)_{n \geq 1}$ is compact in $C([0,T];L^2(\text{Supp} \, \varphi))$. Thus $(\varphi \theta_n)_{n \geq 1}$ converges strongly to $\varphi \theta$ in $C([0,T];L^2(\text{Supp} \, \varphi))$. In conclusion, by (2.9), $(\theta_n)_{n \geq 1}$ converges strongly to $\theta$ in $C([0,T];L^p_{\text{loc}}(\mathbb{R}^2))$ for all $T > 0$ and all $p \in [1, \infty)$.

**Step 2.** Conservation of $L^p$ norms. Formula (2.15) for $p < \infty$ follows from the previous step and (2.9). The case $p = \infty$ follows classically by the convergence of $L^p$ norms to the $L^\infty$ norms.

**Step 3.** strong convergence of $u_n$. We show that $u_n$ converges to $u$ strongly in $L^p(0,T;L^p_{\text{loc}}(\mathbb{R}^2))$ for all $p \in [1, \infty)$. Since by (2.9) and (2.15) $u_n$ and $u$ are uniformly bounded, it is sufficient to prove that
\[ \int_0^T |u_n(t) - u(t)|^p \, dx \rightarrow 0, \]
for a.e. \( x \), all \( T > 0 \) and all \( p > \frac{2}{m-1} \). Now,
\[
u_n(x) - u(x) = \rho_n \ast k^\alpha_m \ast (\theta_n - \theta)(x) + (\rho_n \ast u(x) - u(x)).
\]

Our claim for the second term on the right hand side is standard, so we concentrate on the first term. Given \( R > 0 \), write \( k^\alpha_m = k_m \mathbb{I}_{B_R(0)} \) and \( k^\alpha_0 = k_m \mathbb{I}_{B_R(0)^c} \). By the Hölder and Young inequalities, and (2.9) and (2.15),
\[
\|\rho_n \ast k^\alpha_0 \ast (\theta_n - \theta)\|_{L^\infty} \leq \|k^\alpha_m \ast (\theta_n - \theta)\|_{L^\infty} \leq cR^{-\alpha},
\]
for a number \( \alpha > 0 \), where \( c \) depends on \( \theta_0 \). Since \( \text{Supp} \rho \subset B(0) \),
\[
|\rho_n \ast k^\alpha_m \ast (\theta_n - \theta)(x)| \leq \sup_{y \in B_{\epsilon_n}(x)} |k^\alpha_m \ast (\theta_n - \theta)(y)|.
\]

Using the Hölder inequality with \( q < \frac{2}{m-1} \) and \( \frac{1}{p} + \frac{1}{q} = 1 \) (therefore \( p > \frac{2}{m-1} \)),
\[
|k^\alpha_m \ast (\theta_n - \theta)(y)| \leq \|k^\alpha_m\|_{L^q} \|\mathbb{I}_{B_R(y)}\|_{L^p} \|\theta_n - \theta\|_{L^p} \leq cR\|\mathbb{I}_{B_{R+1}(x)}\|_{L^p} \|\theta_n - \theta\|_{L^p},
\]
since \( y \in B_{\epsilon_n}(x) \) and, for \( n \) large enough, \( \epsilon_n \leq 1 \). In conclusion,
\[
\int_0^T |\rho_n \ast k^\alpha_m \ast (\theta_n - \theta)(x)|^p \, dx \lesssim R^{-\alpha p} + cR \int_0^T \|\mathbb{I}_{B_{R+1}(x)}\|_{L^p}^p \, dt.
\]
By first taking the lim sup in \( n \to \infty \) (using the first step of the proof), and then the limit \( R \uparrow \infty \), the claim follows.

**Step 4.** conclusion. The convergence properties in the first two steps allows immediately to prove that \( \theta \) is a weak solution.

In the analysis of the connection between solutions of (1.1) and the point vortex motion we will need some additional properties of solutions to (1.1).

**Corollary 2.7.** Let \( \theta_0 \in L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2) \), and let \( \theta \) be a solution to (2.1) with initial condition \( \theta_0 \) obtained as in Theorem 2.6 above. Then the following statements hold.

- If \( \theta_0 \geq 0 \) a.e., then \( \theta(t) \geq 0 \) a.e. for all \( t > 0 \).
- If \( \int_{\mathbb{R}^2} |x| \theta_0(x) \, dx < \infty \), then
  \[
  \sup_{[0,T]} \int_{\mathbb{R}^2} |x| \theta(t,x) \, dx < \infty, \quad \text{for all } T > 0,
  \]
  \[
  \int_{\mathbb{R}^2} \theta(t,x) \, dx = \int_{\mathbb{R}^2} \theta_0(x) \, dx, \quad \text{for all } t \geq 0.
  \]
- If \( \int_{\mathbb{R}^2} |x|^2 \theta_0(x) \, dx < \infty \), then
  \[
  \sup_{[0,T]} \int_{\mathbb{R}^2} |x|^2 \theta(t,x) \, dx < \infty, \quad \text{for all } T > 0,
  \]
  \[
  C_{\theta(t)} = \int_{\mathbb{R}^2} x^2 \theta(t,x) \, dx = \int_{\mathbb{R}^2} x \theta_0(x) \, dx = C_{\theta_0}, \quad \text{for all } t \geq 0,
  \]
  \[
  J_{\theta(t)} \leq J_{\theta_0}
  \]

**Proof.** As in the proof of the previous theorem there is a sequence \( (\theta_n)_{n \geq 1} \), with \( \theta_n = \theta_{\epsilon_n} \) and \( u_n = u_{\epsilon_n} \), of solutions to (2.7), with regularized initial condition, such that \( \theta_n \to \theta \) and \( u_n \to u \) as in the proof of Theorem 2.6. Positivity is straightforward by Proposition 2.4.
Assume \( \int_{\mathbb{R}^2} |x| |\theta_0(x)| \, dx < \infty \). By integration by parts,
\[
\frac{d}{dt} \int_{\mathbb{R}^2} |x| |\theta_n| \, dx = \int_{\mathbb{R}^2} |x| \text{sgn}(\theta_n) \partial_t \theta_n \, dx = - \int_{\mathbb{R}^2} |x| u_n \cdot \nabla |\theta_n| \, dx
\]
\[
= \int_{\mathbb{R}^2} |\theta_n| u_n \cdot \nabla |x| \, dx \leq \int_{\mathbb{R}^2} |u_n| |\theta_n| \, dx,
\]
and the last term on the right hand side is uniformly bounded by a number that depends only on \( \theta_0 \). This proves the first claim and that \((\theta_n)_{n \geq 1}\) is uniformly integrable. By (2.10) conservation of mass follows for \( \theta \).

Assume \( \int_{\mathbb{R}^2} |x|^2 |\theta_0(x)| \, dx < \infty \). By integration by parts,
\[
\frac{d}{dt} \int_{\mathbb{R}^2} |x|^2 |\theta_n| \, dx = - \int_{\mathbb{R}^2} |x|^2 u_n \cdot \nabla |\theta_n| \, dx
\]
\[
= \int_{\mathbb{R}^2} |\theta_n| u_n \cdot \nabla |x|^2 \, dx \leq 2 \|u_n\|_{L^\infty} \int_{\mathbb{R}^2} |x| |\theta_n| \, dx,
\]
and, by the previous considerations, the last term on the right hand side is uniformly bounded, on a finite time interval \([0, T]\), by a number that depends only on \( \theta_0 \) and \( T \). This estimates implies that \((x \mapsto x \theta_n(t, x))_{n \geq 1}\) is uniformly integrable, therefore \(C_{\theta_n(t)} \to C_{\theta(t)}\) for all \( t \). Actually, uniform convergence holds, since for \( T > 0 \) and \( t \in [0, T] \),
\[
|C_{\theta_n(t)} - C_{\theta(t)}| \leq \int_{B_R(0)} |x| |\theta_n(t) - \theta(t)| \, dx + \int_{B^c_R(0)} |x| |\theta_n(t) - \theta(t)| \, dx
\]
\[
\leq R \sup_{[0, T]} \|\theta_n - \theta\|_{L^1} + \frac{1}{R} \int_{\mathbb{R}^2} |x|^2 (|\theta_n(t)| + |\theta(t)|) \, dx.
\]

The second term on the right hand side is uniformly bounded in \( n \) and \( t \in [0, T] \). By first taking the limit \( n \to \infty \) and then \( R \uparrow \infty \), uniform convergence follows. We have
\[
\frac{d}{dt} C_{\theta_n(t)} = \int_{\mathbb{R}^2} x \partial_t \theta_n \, dx = - \int_{\mathbb{R}^2} x u_n \cdot \nabla \theta_n \, dx = \int_{\mathbb{R}^2} \theta_n u_n \, dx = 0,
\]
since \( \rho_n \) is symmetric and \( k_m \) is anti-symmetric. This proves conservation of the centre of pseudo-vorticity for \( \theta \). Likewise,
\[
\frac{d}{dt} \int_{\mathbb{R}^2} |x|^2 \theta_n \, dx = - \int_{\mathbb{R}^2} |x|^2 u_n \cdot \nabla \theta_n \, dx = 2 \int_{\mathbb{R}^2} \theta_n u_n \cdot x \, dx = 0,
\]
since \( \rho_n \) is symmetric, \( k_m \) is anti-symmetric, and \( x \cdot k_m(x) = 0 \). By semicontinuity and the conservation of mass and centre proved before, we obtain \( J_{\theta(t)} \leq J_{\theta_0} \).

In Section 3 we will single out the evolution of a single vortex blob and consider the velocity field generated by all other blobs as an external field. To this end the following slight modification of the previous results will be useful.

**Corollary 2.8.** Let \( \theta_0 \in L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2) \), and \( F : [0, \infty) \times \mathbb{R}^2 \to \mathbb{R}^2 \) be a bounded field. Then there is a solution to
\[
\begin{aligned}
\partial_t \theta + \nabla \cdot (u + F) \theta &= 0, \\
u &= k_m * \theta,
\end{aligned}
\]
such that (2.15) holds. Moreover, the conclusions of Corollary 2.7 also hold, with the exception of the evolution of the vortex centre and the moment of inertia, that
are replaced by the following formulas,

\[ C_\theta(t) = C_{\theta_0} + \int_0^t \int_{\mathbb{R}^2} \theta(s, x) F(s, x) \, dx \, ds, \]

\[ J_\theta(t) \leq J_{\theta_0} + 2 \int_0^t \int_{\mathbb{R}^2} \theta(s, x) (x - C_\theta(s)) \cdot F(s, x) \, dx \, ds. \]

3. **The point-vortex motion.** We turn to the main problem, the validation of the point-vortex motion system (1.3) in terms of solutions to (1.1).

For the Euler equations \((m = 2 \text{ in our setting})\) these results have been already established and are somewhat classical, see [30].

We will look rigorously only at the case of the whole plane as a motivation for the validity of the system of evolution for point vortices. The extension of these results to the torus is straightforward, since conservation of the centre of pseudo-vorticity and of the moment of inertia still hold. The presence of boundaries makes the problem more difficult and it is not examined here.

3.1. **Global solutions for the point vortex motion.** Our first step to motivate the point vortex motion system (1.3), is to show that it gives a well defined dynamics, at least for a large enough set of initial conditions. Here we follow the approach used for the Euler equations in [28, 30].

The point vortex motion (1.3) is given by

\[ \dot{X}_j = \sum_{k \neq j} \gamma_k \nabla_{\perp} G_m(X_j, X_k), \quad j = 1, 2, \ldots, N, \]

where \(G_m\) is the Green function of \((-\Delta)^m\) on the whole space, see (1.4). The motion is Hamiltonian, described by the Hamiltonian

\[ H(X_1, X_2, \ldots, X_N; \gamma_1, \gamma_2, \ldots, \gamma_N) = \frac{1}{2} \sum_{j \neq k} \gamma_j \gamma_k G_m(X_j, X_k), \quad (3.1) \]

where \(\gamma_1 \ldots \gamma_N\) are vortex intensities, in the sense that the above system can be written as

\[ \begin{align*}
\gamma_j \dot{X}_{j,1} &= \frac{\partial H}{\partial X_{j,2}}, \\
\gamma_j \dot{X}_{j,2} &= -\frac{\partial H}{\partial X_{j,1}},
\end{align*} \quad j = 1, 2, \ldots, N. \]

Therefore the Hamiltonian \(H\) is conserved along the motion (1.3). Moreover, since the Hamiltonian is translation invariant and rotation invariant, the vortex centre

\[ C = \sum_{j=1}^N \gamma_j X_j, \quad (3.2) \]

and the moment of inertia

\[ J = \sum_{j=1}^N \gamma_j |X_j|^2. \]

are also conserved. Assume initially that all vortex intensities are positive (or all negative). Then by the conservation of the Hamiltonian there cannot be collapse. Additionally, by the conservation of the moment of inertia there cannot be explosion, namely that one or more vortices reach infinity in finite time. For the same reasons, even with vortices of different signs, there cannot be collapse or explosion for one or two vortices. For more than two vortices singularities are possible, see [1].
Our main assumption, the same in [30] for the case \( m = 2 \), for the existence of a global flow for almost every initial condition is
\[
\sum_{j \in J} \gamma_j \neq 0 \quad \text{for all } J \subset \{1, 2, \ldots, N\}. \tag{3.3}
\]
The main theorem is as follows. A version of this result on the torus can be found in [19].

\textbf{Theorem 3.1.} Fix \( 1 < m < 2 \) and assume (3.3). Then, outside a set of initial conditions of Lebesgue measure zero, the initial value problem associated to the vortex equation (1.3) has a global smooth solution.

\textbf{Proof.} The theorem can be proved similarly to [30, Corollary 2.2, Ch. 4], We outline some of the main steps.

First of all we regularize the dynamics, to handle the singularity. Let \( G_{\epsilon m} \) be a \( C^\infty(\mathbb{R}^2) \) function such that
\begin{itemize}
  \item \( G_{\epsilon m} = G_m \) for \( |x| \geq \epsilon \),
  \item \( 0 \leq G_{\epsilon m} \leq G_m \),
  \item \( |\nabla G_{\epsilon m}| \lesssim |\nabla G_m| \).
\end{itemize}
The regularized dynamics \( X_{\epsilon} \) defined by the Hamiltonian obtained by (3.1) by replacing \( G_m \) with \( G_{\epsilon m} \) is well defined and global. Moreover, as long as the particles in the regularized dynamics are at a distance of at least \( \epsilon \), their motion coincide with the original motion given by (1.3).

The first step is to prove a uniform estimate on non-collision. The following claim can be proved as Theorem 2.1 (chapter 4) of [30], with no substantial difference between the case with value \( m = 2 \) (discussed in the reference) and the case \( 1 < m < 2 \).

There exists a number \( c > 0 \) independent of \( \epsilon \) and of the initial condition, such that
\[
\max_{1 \leq j \leq N} \sup_{t \in [0, T]} |X_{\epsilon}^j(t) - X_j^0(0)| \leq c.
\]
The proof is based essentially on the conservation of the vortex centre, defined as in (3.2). Here the assumption (3.3) is essential, while it is only required that \( |\nabla G_m| \) goes to zero at infinity\(^1\).

The previous claim implies that

For every \( R, T > 0 \), there is \( R_0 > 0 \) such that \( N \) vortices that start in \( B_R(0) \) and evolve with the regularized dynamics, cannot leave \( B_{R_0}(0) \) within time \( T \), for every initial data and every \( \epsilon \in (0, 1) \).

Define
\[
D_T(x_1, \ldots, x_N) = \min_{i \neq j} \min_{t \in [0, T]} |X_i(t) - X_j(t)|, 
\]
where \( X(\cdot) \) is the dynamics (1.3) with initial condition \((x_1, \ldots, x_N)\). Define similarly \( D_T^\epsilon(x_1, \ldots, x_N) \) for the regularized dynamics. To prove the theorem, it is sufficient to prove that the set \( \{D_T(x_1, \ldots, x_N) = 0\} \) has Lebesgue measure zero. To this end, it suffices to prove that the measure of \( \{D_T(x_1, \ldots, x_N) < \epsilon\} \cap B^N_R \) converges to \( 0 \) as \( \epsilon \downarrow 0 \) for all \( R \), where \( B^N_R \) is the product of \( N \)-times the ball \( B_R(0) \). But since
\[
\{D_T(x_1, \ldots, x_N) \geq \epsilon\} \cap B^N_R = \{D_T^\epsilon(x_1, \ldots, x_N) \geq \epsilon\} \cap B^N_R
\]
\(^1\)So in principle every \( m \leq 2 \) is allowed.
this is the same as proving that the measure of \( \{ D^\epsilon_T(x_1, \ldots, x_N) < \epsilon \} \cap B_R^N \) goes to 0 as \( \epsilon \downarrow 0 \).

Define
\[
\Phi_\epsilon(x_1, \ldots, x_N) = \frac{1}{2} \sum_{i \neq j} G^\epsilon_m(x_i - x_j),
\]
and let \( X^\epsilon \) be the solution to the regularized dynamics with initial conditions \( x_1, \ldots, x_N \). A simple computation yields
\[
\frac{d}{dt} \Phi_\epsilon(X^\epsilon_t(t), \ldots, X^\epsilon_N(t)) \leq \sum_{i \neq j, j \neq k, k \neq i} 1
\]
where the most singular term has disappeared due to the product \( \nabla \cdot \nabla^\perp \) being zero. Notice that since \( m > 1 \), \( \Phi_\epsilon \) and \( h \) are in \( L^1_{\text{loc}} \), and the integral of \( \Phi_\epsilon \) and \( h \) over bounded sets is independent of \( \epsilon \). Using the invariance of the Lebesgue measure with respect to the regularized dynamics and the second claim above,
\[
\int_{B_R^N} \sup_{[0, T]} |\Phi_\epsilon(X^\epsilon_t)| \, dx_1 \ldots \, dx_N \leq \int_{B_R^N} |\Phi_\epsilon(x_1, \ldots, x_N)| \, dx_1 \ldots \, dx_N
\]
Finally, \( \{ D^\epsilon_T(x_1, \ldots, x_N) < \epsilon \} \cap B_R^N \subset \sup_{[0, T]} |\Phi_\epsilon(X^\epsilon_t)| \geq \frac{1}{T} e^{m-2} \}, \) and the measure of the set on the right hand side, by the Chebychev inequality, is bounded by \( 2e^{m-2}C(T, R_\epsilon) \) and thus converges to 0.

3.2. Vortex approximation. In this section we prove that vortices provide an approximation of solutions to (1.1). These results are classical for \( m = 2 \), see [30], and have been recently proved for \( m \in (2, 3) \) in [21].

First, we set up the initial conditions for the approximation. Let \( \theta_0 \in L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2) \), with \( \int_{\mathbb{R}^2} |x| \, |\theta_0(x)| \, dx < \infty \). For every \( N \geq 2 \) consider \( \gamma_1^N, \gamma_2^N, \ldots, \gamma_N^N \in \mathbb{R} \) and \( x_1^N, x_2^N, \ldots, x_N^N \) such that
\[
\sum_{j=1}^N \gamma_j^N_+ = \int_{\mathbb{R}^2} \theta_0(x)_+ \, dx, \quad \sum_{j=1}^N \gamma_j^N_- = \int_{\mathbb{R}^2} \theta_0(x)_- \, dx,
\]
where \( x_+ = x \vee 0 \) and \( x_- = (-x) \vee 0 \), and set
\[
\theta_0^N = \sum_{j=1}^N \gamma_j^N \delta_{x_j^N}.
\]
For every \( \epsilon > 0 \) consider a smooth approximation \( k^\epsilon_m \) of the kernel \( k_m \)
\footnote{For instance, one can consider the smooth approximation \( k^\epsilon_m = \rho_* k_m \) considered in Proposition 2.4, as well as \( k^\epsilon_m = \eta \ast k_m \), where \( \eta \) is a radial function (so that \( k^\epsilon_m \) is still divergence-free) which is 1 in \( B_{2^\epsilon}(0) \) and 0 in \( B_\epsilon(0) \).}
, and consider the solution \( (X_{\epsilon,j}^N)_{j=1,2,\ldots,N} \) of the evolution
\[
\dot{X}_{\epsilon,j}^N = \sum_{k=1}^N \gamma_{\epsilon,j,k}^N k^\epsilon_m (X_{\epsilon,j}^N - X_{\epsilon,k}^N),
\]
with initial conditions \( x_1^N, x_2^N, \ldots, x_N^N \). Set finally
\[
\theta_\epsilon^N(t) = \sum_{j=1}^N \gamma_{\epsilon,j}^N \delta_{X_{\epsilon,j}^N(t)}, \quad t \geq 0.
\]
Claim (3.6) now follows by taking first the limit in two sequences

\[ \lim_{n \to \infty} W_1(\theta^n_N, \theta_0) = 0, \quad \text{as } N \to \infty. \]

Let \( \theta \) be a solution of (1.1) given by Theorem 2.6. Then for every \( T > 0 \) there are two sequences \((\epsilon_n)_{n \geq 1}\) and \((N_n)_{n \geq 1}\) such that

\[ \sup_{t \in [0,T]} W_1(\theta^n_N(t), \theta(t)) \to 0, \quad \text{as } n \to \infty. \]

**Remark 3.3.** Condition (3.4) is only technical in view of the evaluation in terms of the Wasserstein distance, since the Wasserstein distance can be infinite in case of measures with different masses. In case (3.4) holds only asymptotically, the solution is to compare \( \theta^n_N \) with a modification of \( \theta_0 \) such that the equality of masses is re-established and the modification weakly converges to \( \theta_0 \).

**Remark 3.4.** There are two oddities about the theorem above. The first is about the limit along a sequence of regularizations \((\epsilon_n)_{n \geq 1}\). In the analogous result on Euler equations \((m = 2)\) this is not required, and this is due to the fact that uniqueness for initial conditions in \( L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2) \) is not known when \( m < 2 \) (but see also Remark 3.5 in view of the uniqueness proof of Corollary 2.5).

The second issue regards the appearance of the regularized dynamics in place of the original dynamics (1.3). Consider for simplicity the regularization \( \eta \), where \( \eta \) is smooth, bounded, radial, equal to 1 everywhere but in \( B_r(0) \), and 0 in \( B_{r/2}(0) \). With this choice it is immediate to see that the solutions to (1.3) and (3.5) are the same as long as

\[ D_N := \min_{t \in [0,T]} \min_{i \neq j} |X^N_j(t) - X^N_i(t)| \]

is larger than \( \epsilon \), where \( X^N \) is the solution to (1.3). The problem is now apparent: in order to consider the true dynamics we need to have \( D_N \ll \epsilon \), which in principle means \( N \) not too large. On the other hand, condition (3.7) in the proof requires to have \( N \) large, to compensate for the diverging constant.

**Proof of Theorem 3.2.** It is not difficult to see through Corollary 2.5 and the proof of Theorem 2.6 that there is a sequence \((\epsilon_n)_{n \geq 1}\) such that \( \theta_n \to \theta \) strongly in \( C([0,T]; L^p_{\text{loc}}(\mathbb{R}^2)) \) for all \( p \in [1,\infty) \), where \( \theta_n \) is the solution to (2.7) with initial condition \( \theta_0 \).

Let us prove that

\[ \sup_{t \in [0,T]} W_1(\theta_n(t), \theta(t)) \to 0. \]  

(3.6)

Indeed, it suffices to prove the same statement with the Wasserstein metric replaced by the \( L^1 \) metric. As in Corollary 2.7, we can prove that

\[ c_0 := \sup_{n \geq 1} \sup_{t \in [0,T]} \int_{\mathbb{R}^2} |x| |\theta_n(t)| dx < \infty, \]

and this holds in the limit for \( \theta \). Therefore, if \( R > 0 \), for all \( t \in [0,T] \),

\[ \int_{B_R(0)^c} |\theta_n(t,x) - \theta(t,x)| dx \leq \frac{2c_0}{R}, \]

and

\[ \sup_{t \in [0,T]} ||\theta_n(t) - \theta(t)||_{L^1} \leq \sup_{t \in [0,T]} \|\mathbb{1}_{B_R(0)}(\theta_n(t) - \theta(t))\|_{L^1} + \frac{2c_0}{R}. \]

Claim (3.6) now follows by taking first the limit in \( n \to \infty \) and then in \( R \to \infty \).
Remark 3.5. The assumption first construct a suitable coupling of other. Therefore it is sufficient to prove contraction with respect to a coupling. We an infimum over the transportation cost of the mass from one distribution to the \( \theta \) read as a contraction in Wasserstein distance. The same ideas do not work in this characteristics. Indeed, by Lemma 2.2 we can expect a Hölder continuous velocity field. When \( m \) is non-negative and of total mass one. Recall that the Wasserstein distance is non-negative and of total mass one. See \([29]\), that we partially follow. More singularity may be allowed, namely a bound \( \eta = \frac{m(m-1)}{3-m} \).

By Corollary 2.5,
\[
\sup_{t \in [0,T]} W_1(\theta_{\epsilon_n}(t), \theta_{\epsilon_n}^N(t)) \leq C(\epsilon, T) W_1(\theta_0^N, \theta_0).
\]
Indeed, it is not difficult to check that \( \theta_0^N \) is a solution to (2.7).

Finally, choose \( (N_n)_{n \geq 1} \) so that
\[
C(\epsilon, T) W_1(\theta_0^N, \theta_0) \to 0,
\]
as \( n \to \infty \). Then
\[
W_1(\theta_{\epsilon_n}(t), \theta(t)) \leq W_1(\theta_{\epsilon_n}^N(t), \theta_{\epsilon_n}(t)) + W_1(\theta_{\epsilon_n}(t), \theta(t)).
\]
and this proves the theorem. \( \square \)

Remark 3.5. The assumption \( \int_{\mathbb{R}^2} |x| |\theta_0(x)| \, dx \) seems a bit too strong. The same results hold without that assumption in the case \( m = 2 \), see \([27]\). A basic reason is that in this more singular case one does not expect to have well-defined characteristics. Indeed, by Lemma 2.2 we can expect a Hölder continuous velocity field. When \( m = 2 \) velocity is Lipschitz, up to a logarithmic correction, and this can be read as a contraction in Wasserstein distance. The same ideas do not work in this framework. Let us give a few details, and assume for simplicity of exposition that \( \theta_0 \) is non-negative and of total mass one. Recall that the Wasserstein distance is an infimum over the transportation cost of the mass from one distribution to the other. Therefore it is sufficient to prove contraction with respect to a coupling. We first construct a suitable coupling of \( \theta_{\epsilon}(t) \) and \( \theta_{\delta}(t) \), for some \( \epsilon, \delta > 0 \), using the characteristics \( X_\epsilon \) of (2.7), as in the proof of Corollary 2.5, namely
\[
f \mapsto \int_{\mathbb{R}^2} f(X_\epsilon^x(t), X_\delta^x(t)) \theta_0(x) \, dx
\]
Set
\[
\Psi(t) = \int_{\mathbb{R}^2} |X_\epsilon^x(t) - X_\delta^x(t)| \theta_0(x) \, dx,
\]
then using Lemma 2.2, eventually one gets,
\[
\dot{\Psi} \leq \epsilon^{m-1} + \Psi^{m-1}.
\]
Since \( m < 2 \), the above differential inequality does not ensure that \( \Psi \to 0 \) as \( \epsilon, \delta \to 0 \), as it happens when \( m \geq 2 \) (with a logarithmic correction that does not change the result when \( m = 2 \)).

3.3. A derivation of the vortex model. In this section we wish to prove conversely the connection between the vortex evolution (1.3) and the equation (1.1). Similar results for \( m = 2 \) can be found in \([29]\), that we partially follow. Fix \( N \geq 1 \), \( \gamma_1, \gamma_2, \ldots, \gamma_N \in \mathbb{R} \), and \( N \) points \( x_1^0, x_2^0, \ldots, x_N^0 \in \mathbb{R}^2 \). For every \( \epsilon > 0 \), consider a family of functions \( \theta_{0,1}^\epsilon, \theta_{0,2}^\epsilon, \ldots, \theta_{0,N}^\epsilon \) such that for all \( j = 1, 2, \ldots, N, \)
- \( \text{Supp} \theta_{0,j}^\epsilon \subset B_\epsilon(x_j^0) \),
- \( \theta_{0,j}^\epsilon \geq 0 \) a.e.,
- \( \int |\theta_{0,j}^\epsilon| \leq \epsilon^{-2} \),
- \( \int_{\mathbb{R}^2} \theta_{0,j}^\epsilon(x) \, dx = 1 \),
- \( \sup_{\epsilon>0} \int_{\mathbb{R}^2} |x|^2 \theta_{0,j}^\epsilon(x) \, dx < \infty \).

More singularity may be allowed, namely a bound \( \epsilon^{-2\eta} \) with \( 1 \leq \eta < \frac{m(m-1)}{3-m} \).
A simple example of this setting is given by vortex blobs, namely we set \( \theta_{0,j}^\epsilon = \epsilon^{-2}\eta_j((x-x_j^0)/\epsilon) \), where each \( \eta_j \) is non-negative, bounded, with support in \( B_1(0) \), and with integral equal to 1 on \( \mathbb{R}^2 \).

Define
\[
\theta_\epsilon(0, x) = \sum_{j=1}^N \gamma_j \theta_{0,j}^\epsilon(x),
\]
where \( \gamma_1, \ldots, \gamma_N \) are the intensities of each vortex blob, \( x_1^0, \ldots, x_N^0 \) are the centers, and \( \epsilon \) is small enough that the balls \( (B_\epsilon(x_j^0))_{j=1,\ldots,N} \) are disjoint.

In the theorem below, we assume that the vortex evolution (1.3) with initial condition \( (x_1^0, x_2^0, \ldots, x_N^0) \) has a global solution. According to Theorem 3.1, this happens for a.e. choice of \( (x_1^0, x_2^0, \ldots, x_N^0) \) if the intensities are as in (3.3).

**Theorem 3.6.** Assume \( \sqrt{3} < m < 2 \) and denote by \( \theta_\epsilon \) a solution to (1.1), according to Theorem 2.6, with initial condition \( \theta_\epsilon(0) \) given by (3.8). Then for all \( T > 0 \),
\[
\lim_{\epsilon \to 0} \langle \theta_\epsilon(t), \phi \rangle = \sum_{j=1}^N \phi(X_j(t)), \quad t \in [0, T],
\]
where \( (X_j)_{j=1,\ldots,N} \) is the solution of the vortex evolution (1.3) with vortex intensities \( \gamma_1, \gamma_2, \ldots, \gamma_N \) and with initial conditions \( (x_1^0, x_2^0, \ldots, x_N^0) \).

The proof of this result follows broadly the proof of [29, Theorem 2.1]. It is based on a series of results that we prove in Section 3.3.1.

**Remark 3.7.** In principle, an analogous result can be proved in the case of the evolution in bounded domains, with additional difficulties due to the boundary: there is non-conservation of centre and moment of inertia, one should clarify in general the definition of fractional Laplacian in terms of the boundary conditions, the Green function one obtains is more singular also on the boundary, etc. In particular, the presence of the boundary creates an effect of self-interaction on point vortices.

This does not happen on the torus, and there is no effect of self-interaction. We wish to discuss briefly and heuristically how the self-interaction term disappears in system (1.3) on the torus. First of all, we notice that a structure theorem for the Green function \( G_{\text{per}}^m \) on the torus holds in terms of the Green function (1.4) on the whole space, namely \( G_{\text{per}}^m = G_m^\epsilon + g_{\text{per}}^m \). By translation invariance, we have that \( g_{\text{per}}^m(x,y) = g_{\text{per}}^m(x-y) \) and \( g_{\text{per}}^m \) is bounded.

Following [30], a heuristic motivation for the self-interaction term can be seen as follows. Consider a single vortex blob, as in (3.8), of intensity \( \gamma \) centred at \( x_0 \in \mathbb{T}_2 \), for instance \( \theta_\epsilon(x) = \gamma \epsilon^{-2}\eta(x/\epsilon) \). Assume moreover that \( \eta \) is radial. By the decomposition discussed above,
\[
u_\epsilon(x_0) = \int_{\mathbb{T}_2} \nabla_x G_m(x_0,y)\theta_\epsilon(y) \, dy + \int_{\mathbb{T}_2} \nabla_x g_{\text{per}}^m(x_0,y)\theta_\epsilon(y) \, dy
\]
The first integral is zero by symmetry, and since \( \theta_\epsilon \to \gamma \delta_0 \), the second integral converges,
\[
\int_D \nabla_x g_{\text{per}}^m(x_0,y)\theta_\epsilon(y) \, dy \to \gamma \nabla_x g_{\text{per}}^m(x_0,0).
\]
In conclusion \( u_\epsilon(x_0) \to \gamma \nabla_x g_{\text{per}}^m(x_0,0) \), and \( \gamma \nabla_x g_{\text{per}}^m(x_0,0) \) can be considered the velocity field generated by the vortex itself. By translation invariance this term is 0 and confirms the validity of the evolution (1.3). As a final remark, notice that
this heuristic argument strongly depends on the symmetry of the vortex blob. If the blob shape is not symmetric, then the integrals above may diverge.

3.3.1. Convergence of vortex blobs to point-vortices. The following proposition is the version of [29, Theorem 3.1] in our setting, and proves Theorem 3.6 above for a single point vortex subject to an additional external velocity field. A major outcome of the proposition below is the property of localisation, namely the evolution of (1.1) started on a vortex blob stays around the centre of pseudo-vorticity.

First, we single out the initial condition from the setting of Theorem 3.6. Fix $x_0 \in \mathbb{R}^2$ and $T > 0$. Consider a family $(\theta_\epsilon(0))_{\epsilon > 0}$ such that

- $\theta_\epsilon(0) : \mathbb{R}^2 \to \mathbb{R}$ non-negative functions,
- $\text{Supp}(\theta_\epsilon(0)) \subset B_r(x_0)$,
- $|\theta_\epsilon(0,x)| \lesssim \epsilon^{-2}$, for all $x$,
- $\int_{\mathbb{R}^2} \theta_\epsilon(0,x) \, dx = 1$ and $\int_{\mathbb{R}^2} |x|^2 \theta_\epsilon(0,x) \, dx < \infty$.

Moreover, consider a family $(F_\epsilon)_{\epsilon > 0}$ such that

- $F_\epsilon : [0,T] \times \mathbb{R}^2 \to \mathbb{R}^2$ are continuous divergence-free vector fields,
- $F_\epsilon$ uniformly bounded (in $t,x,\epsilon$),
- $F_\epsilon$ uniformly Lipschitz in the space variable, with common Lipschitz constant $M > 0$,
- there is $F : [0,T] \times \mathbb{R}^2 \to \mathbb{R}^2$ such that
  $$\sup_{t \in [0,T], x \in \mathbb{R}^2} \|F_\epsilon - F\|_{L^\infty([0,T] \times \mathbb{R}^2)} \lesssim \epsilon,$$
- $\text{Supp}(F_\epsilon(t))$ is contained in a ball centred at $c(t)$ and with radius of order $O(\epsilon)$, for every $t \in [0,T]$.

Here $c$ is the solution to

$$\begin{cases}
  \dot{c} = F(t,c), \\
  c(0) = x_0.
\end{cases} \tag{3.9}$$

**Proposition 3.8.** Let $\sqrt{3} < m < 2$ and consider $x_0$, $T$, $(\theta_\epsilon(0))_{\epsilon > 0}$ and $(F_\epsilon)_{\epsilon > 0}$, $F$ as above. Denote by $\theta_\epsilon$ a solution, according to Corollary 2.8 of

$$\begin{cases}
  \partial_t \theta + \nabla \cdot ((u + F_\epsilon) \theta) = 0, \\
  u = k_m * \theta,
\end{cases}$$

with initial condition $\theta_\epsilon(0)$. Finally denote by $c_\epsilon$ the centre of pseudo-vorticity of $\theta_\epsilon(t)$ (see (2.2)). Then

1. $c_\epsilon \to c$ uniformly in $t \in [0,T]$,
2. For every $\phi \in C^1_b(\mathbb{R}^2)$,
   $$\theta_\epsilon(t,\phi) \overset{\epsilon \to 0}{\longrightarrow} \phi(c(t)), \quad \text{uniformly in } t \in [0,T],$$
3. For every $R > 0$ there is $\epsilon_0 = \epsilon_0(R,T) > 0$ such that, if $\epsilon \leq \epsilon_0$, then $\text{Supp}(\theta_\epsilon(t)) \subset B_R(c_\epsilon(t))$ for $t \in [0,T]$.

**Proof.** The proof follows the proof of [29, Theorem 3.1], with some non-trivial changes due to the more singular problem.

**Step 1.** The evolution of $c_\epsilon$. As in Corollary 2.7,

$$\frac{dc_\epsilon}{dt} = \int_{\mathbb{R}^2} x \partial_t \theta_\epsilon \, dx = -\int_{\mathbb{R}^2} x \nabla \cdot ((u_\epsilon + F_\epsilon) \theta_\epsilon) \, dx$$

$$= \int_{\mathbb{R}^2} \theta_\epsilon (u_\epsilon + F_\epsilon) \, dx \int_{\mathbb{R}^2} \theta_\epsilon F_\epsilon \, dx, \tag{3.10}$$
since \( u_\epsilon = k_m \ast \theta_\epsilon \) and \( k_m \) is anti-symmetric, so that
\[
\int_{\mathbb{R}^2} \theta_\epsilon(t,x)u_\epsilon(t,x) \, dx = \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} k_m(x-y)\theta_\epsilon(t,x)\theta_\epsilon(t,y) \, dx \, dy = 0.
\]
Moreover, by an elementary computation \( |c_\epsilon(0) - x_0| \lesssim \epsilon \).

**Step 2.** The evolution of the moment of inertia. Set
\[
J_\epsilon(t) := \int_{\mathbb{R}^2} |x - c_\epsilon(t)|^2 \theta_\epsilon(t,x) \, dx = \int_{\mathbb{R}^2} |x|^2 \theta_\epsilon(t,x) \, dx - c_\epsilon(t)^2.
\]
By our assumptions, \( J_\epsilon(0) \lesssim \epsilon^2 \). Then, as in Corollary 2.7, by (3.10),
\[
\frac{dJ_\epsilon(t)}{dt} = \int_{\mathbb{R}^2} |x|^2 \partial_t \theta_\epsilon \, dx - 2c_\epsilon \theta_\epsilon
= - \int_{\mathbb{R}^2} |x|^2 \nabla \cdot (u_\epsilon(t) + F_\epsilon \theta_\epsilon) \, dx - 2c_\epsilon \int_{\mathbb{R}^2} \theta_\epsilon \cdot F_\epsilon \, dx
= 2 \int_{\mathbb{R}^2} (x - c_\epsilon) \cdot F_\epsilon \theta_\epsilon \, dx + 2 \int_{\mathbb{R}^2} x \cdot u_\epsilon \theta_\epsilon \, dx
= 2 \int_{\mathbb{R}^2} (x - c_\epsilon) \cdot F_\epsilon \theta_\epsilon \, dx.
\]
Here \( \int_{\mathbb{R}^2} x \cdot u_\epsilon \theta_\epsilon \, dx \) is zero since \( k_m \) is anti-symmetric, \( x \cdot k_m(x) = 0 \) and, by symmetrisation,
\[
\int_{\mathbb{R}^2} \theta_\epsilon(t,x)u_\epsilon(t,x) \cdot x \, dx = \frac{1}{2} \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} (x - y) \cdot k_m(x - y)\theta_\epsilon(t,x)\theta_\epsilon(t,y) \, dx \, dy.
\]
By the definition of centre of pseudo-vorticity,
\[
\frac{dJ_\epsilon(t)}{dt} = 2 \int_{\mathbb{R}^2} \theta_\epsilon(t,x)(x - c_\epsilon(t)) \cdot (F_\epsilon(t,x) - F_\epsilon(t,c_\epsilon(t))) \, dx
\leq 2M \int_{\mathbb{R}^2} |x - c_\epsilon(t)|^2 \theta_\epsilon(t,x) \, dx = 2MJ_\epsilon(t),
\]
therefore,
\[
\sup_{\epsilon \in [0,T]} J_\epsilon(t) \lesssim \epsilon^2. \tag{3.11}
\]

**Step 3.** Convergence of the centre of pseudo-vorticity. Consider the solution \( c(t) \) of (3.9) and recall (3.10). Using the conservation of \( \theta_\epsilon \),
\[
c_\epsilon(t) - c(t) = c_\epsilon(0) - c(0) + \int_0^t \left( F_\epsilon(s,c_\epsilon(s)) - F_\epsilon(s,c(s)) \right) \, ds + \int_0^t \left( F_\epsilon(s,c(s)) - F(s,c(s)) \right) \, ds + \int_0^t \int_{\mathbb{R}^2} (F_\epsilon(s,x) - F_\epsilon(s,c_\epsilon(s)))\theta_\epsilon(s,x) \, dx \, ds,
\]
therefore, by (3.11) and the assumptions on \( F_\epsilon \),
\[
|c_\epsilon(t) - c(t)| \lesssim \epsilon + M \int_0^t |c_\epsilon(s) - c(s)| \, ds + M \int_0^t \int_{\mathbb{R}^2} |x - c_\epsilon(s)|\theta_\epsilon(s,x) \, dx \, ds
\leq \epsilon + M \int_0^t |c_\epsilon(s) - c(s)| \, ds + M \int_0^t J_\epsilon(s)^{1/2} \, ds
\lesssim \epsilon + M \int_0^t |c_\epsilon(s) - c(s)| \, ds.
\]
By Gronwall’s Lemma,

\[ \sup_{[0,T]} |c(t) - c_\epsilon(t)| \lesssim \epsilon. \]

**Step 4.** Convergence of the pseudo-vorticity. Let \( \phi \) be a test function. From (3.11),

\[ \int_{\mathbb{R}^2} \phi(x) \theta_\epsilon(t, x) \, dx - \phi(c_\epsilon(t)) = \int_{\mathbb{R}^2} \theta_\epsilon(t, x)(\phi(x) - \phi(c_\epsilon(t))) \, dx \]

\[ \leq \|\nabla \phi\|_\infty \int_{\mathbb{R}^2} \theta_\epsilon(t, x)|x - c_\epsilon(t)| \, dx \leq \|\nabla \phi\|_\infty J_\epsilon(s)^{1/2} \lesssim \epsilon. \]

Since by Step 3, \( c_\epsilon \to c \) uniformly, it follows that

\[ \sup_{[0,T]} \left| \int_{\mathbb{R}^2} \phi(x) \theta_\epsilon(t, x) \, dx - \phi(c(t)) \right| \lesssim \epsilon. \]

**Step 5.** Control of the support of the pseudo-vorticity. We use the idea of [29] to prove that the amount of pseudo-vorticity crossing the boundary of a small ball around \( c_\epsilon \) is small. This allows to prove that the radial part of the velocity is also small and pseudo-vorticity cannot spread out away from \( c_\epsilon \).

Let \( \delta \in (0, 1) \) and consider a radial function \( \phi_\delta \in C^\infty \) such that \( 0 \leq \phi_\delta \leq 1 \), and

\[ \phi_\delta = \begin{cases} 
1, & |x| \leq \delta, \\
0, & |x| \geq 2\delta,
\end{cases} \quad |\nabla \phi_\delta| \lesssim \frac{1}{\delta}, \quad |D^2 \phi_\delta| \lesssim \frac{1}{\delta^2}. \]

Let

\[ \mu_\delta = 1 - \int_{\mathbb{R}^2} \phi_\delta(c_\epsilon(t) - x) \theta_\epsilon(t, x) \, dx. \]

We have

\[ \frac{d}{dt} \mu_\delta = \int_{\mathbb{R}^2} \nabla \phi_\delta(c_\epsilon(t) - x) \cdot (u_\epsilon + F_\epsilon) \theta_\epsilon \, dx - \int_{\mathbb{R}^2} \mathcal{C}_\delta(t) \cdot \nabla \phi_\delta(c_\epsilon(t) - x) \theta_\epsilon \, dx =: \Box + \Box. \]

By conservation of mass and definition of \( u_\epsilon \),

\[ \Box = \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \nabla \phi_\delta(c_\epsilon(t) - x) \cdot k_m(x - y) \theta_\epsilon(t, x) \theta_\epsilon(t, y) \, dx \, dy \]

\[ + \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \nabla \phi_\delta(c_\epsilon(t) - x) \cdot F_\epsilon(t, x) \theta_\epsilon(t, x) \theta_\epsilon(t, y) \, dx \, dy, \]

and by (3.10),

\[ \Box = - \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \nabla \phi_\delta(c_\epsilon(t) - x) \cdot F_\epsilon(t, y) \theta_\epsilon(t, x) \theta_\epsilon(t, y) \, dy \, dx, \]

so that,

\[ \frac{d}{dt} \mu_\delta = \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \nabla \phi_\delta(c_\epsilon(t) - x) \cdot (F_\epsilon(t, x) - F_\epsilon(t, y)) \theta_\epsilon(t, x) \theta_\epsilon(t, y) \, dy \, dx \]

\[ + \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \nabla \phi_\delta(c_\epsilon(t) - x) \cdot k_m(x - y) \theta_\epsilon(t, x) \theta_\epsilon(t, y) \, dy \, dx =: \Box + \Box. \]

To estimate \( \Box \) and \( \Box \) we set some positions and give some useful inequalities. Let

\[ m_\delta(t) = \int_{B_\delta(c_\epsilon(t))^c} \theta_\epsilon(t, x) \, dx \]

(3.12)
be the amount of pseudo-vorticity outside the ball of radius \( \delta \) centred at \( c_\epsilon(t) \), and notice that
\[
\begin{align*}
    m_\delta(t) & \leq \frac{1}{\delta^2} \int_{B_\delta(c_\epsilon(t))}^c |c_\epsilon(t) - x|^2 \theta_\epsilon(t,x) \, dx = \frac{1}{\delta^2} J_\epsilon(t) \lesssim \frac{\epsilon^2}{\delta^2}.
\end{align*}
\] (3.13)

Let us start with the estimate of \( \square \) and split the integral in \( y \) into an integral over \( B_\delta(c_\epsilon(t)) \) and an integral over \( B_\delta^c(c_\epsilon(t)) \),
\[
\begin{align*}
    \square B_\delta(c_\epsilon(t)) & \leq 2 \| F_\epsilon \|_\infty \int \int_{B_\delta(c_\epsilon(t))} |\nabla \phi_\delta(c_\epsilon(t) - x)| \theta_\epsilon(t,x) \theta_\epsilon(t,y) \, dy \, dx \lesssim \frac{1}{\delta} m_\delta(t)^2,
\end{align*}
\]
since \( \nabla \phi_\delta(c_\epsilon(t) - x) = 0 \) if \( |c_\epsilon(t) - x| \leq \delta \), and
\[
\begin{align*}
    \square B_\delta^c(c_\epsilon(t)) & \leq M \int_{B_{2\delta}(c_\epsilon(t))} \int_{B_{\delta}(c_\epsilon(t))} \frac{|x - y|}{\delta} \theta_\epsilon(t,x) \theta_\epsilon(t,y) \, dy \, dx \lesssim m_\delta(t),
\end{align*}
\]
since \( \nabla \phi_\delta(c_\epsilon(t) - x) \neq 0 \) only if \( \delta < |c_\epsilon(t) - x| < 2\delta \). In conclusion
\[
\square \lesssim m_\delta(t) + \frac{1}{\delta} m_\delta(t)^2.
\]

We turn to the analysis of \( \square \). Since the integrand is zero when \( x \in B_\delta(c_\epsilon(t)) \), it is sufficient to consider the integral only over \( E_1 \cup E_2 \), where
\[
\begin{align*}
    E_1 & = B_\delta(c_\epsilon(t))^c \times B_\delta^c(c_\epsilon(t)), \\
    E_2 & = B_\delta(c_\epsilon(t))^c \times B_\delta^c(c_\epsilon(t))^c \cup B_\delta(c_\epsilon(t))^c \times B_\delta^c(c_\epsilon(t))^c,
\end{align*}
\]
and \( \delta = 2\delta \). Denote for brevity by \( \square_{E_1} \) and \( \square_{E_2} \) the parts of the integral of \( \square \) over \( E_1 \) and \( E_2 \). Since \( \phi_\delta \) is radial, we have that \( \nabla \phi_\delta(x) \cdot k_m(x) = 0 \), therefore,
\[
\begin{align*}
    \square_{E_1} & = \int_{E_1} \left( k_m(x - y) - k_m(x - c_\epsilon(t)) \right) \cdot \nabla \phi_\delta(c_\epsilon(t) - x) \theta_\epsilon(t,x) \theta_\epsilon(t,y) \, dy \, dx \\
    & \lesssim \frac{1}{\delta} \int_{E_1} \frac{|y - c_\epsilon(t)|}{\delta^{-m}} \theta_\epsilon(t,x) \theta_\epsilon(t,y) \, dy \, dx \\
    & \lesssim \delta^m m_\delta(t).
\end{align*}
\]
Here we have used conservation of mass and
\[
\begin{align*}
    |k_m(x) - k_m(y)| \lesssim \frac{|x - y|}{\delta^{-m}}, \quad |x|, |y| \geq \delta.
\end{align*}
\] (3.14)

We turn to \( \square_{E_2} \). The domain \( E_2 \) is symmetric in \( x, y \), therefore by symmetrisation, and using that \( k_m \) is anti-symmetric,
\[
\begin{align*}
    \square_{E_2} & = \frac{1}{2} \int_{E_2} k_m(x - y) \cdot \left( \nabla \phi_\delta(c_\epsilon(t) - x) - \nabla \phi_\delta(c_\epsilon(t) - y) \right) \theta_\epsilon(t,x) \theta_\epsilon(t,y) \, dy \, dx \\
    & \lesssim \frac{1}{\delta^2} \int_{E_2} |y - x|^{m-2} \theta_\epsilon(t,x) \theta_\epsilon(t,y) \, dy \, dx \\
    & = \frac{2}{\delta^2} \int_{B_\delta(c_\epsilon(t))^c} \theta_\epsilon(t,x) \int_{B_{\delta^c}(c_\epsilon(t))^c} |x - y|^{m-2} \theta_\epsilon(t,y) \, dy \, dx.
\end{align*}
\]
By definition (3.12) and since \( \theta_\epsilon(t,y) \leq \| \theta_\epsilon(0) \|_\infty \sim \epsilon^{-2} \), by the Hardy-Littlewood-Sobolev inequality,
\[
\begin{align*}
    \int_{B_{\delta^c}(c_\epsilon(t))^c} |x - y|^{m-2} \theta_\epsilon(t,y) \, dy \lesssim \epsilon^{-2(1-m/2)} m_{\delta^c}(t)^{m/2}.
\end{align*}
\]
therefore
\[ \psi \leq \frac{\epsilon^{m-2}}{\delta^2} \delta^{(m/2)m} \delta(t). \]

In conclusion
\[ \psi(t) \leq \delta^{m} \delta(t) + \frac{\epsilon^{m-2}}{\delta^2} \delta^{m} \delta(t)m/2 \delta(t), \]
and, using (3.13),
\[ \frac{d}{dt} \mu(t) \leq \delta \delta(t) + \frac{\epsilon}{\delta^2} \delta \delta(t) + \frac{\epsilon^{m-2}}{\delta^2} \delta^{m} \delta(t)m/2 \delta(t) \]
\[ \leq \mu(t) + \frac{\epsilon^4}{\delta^5} + \frac{\epsilon^{2m}}{\delta^{1+5m}} \leq \mu(t) + \frac{\epsilon^{2m}}{\delta^{1+5m}}. \]

Finally, since \( \phi_{\delta/2} \leq 1_{B_{\delta}}(0) \) hence \( \mu(t) \leq \mu_{\delta/2}(t) \), we have that for \( t \in [0, T] \),
\[ \mu(t) \leq \mu(0) + cT \frac{\epsilon^{2m}}{\delta^{1+5m}} + c \int_{0}^{t} \mu(s) ds, \] (3.15)

where \( c \) is a number that does not depend on the parameters \( \epsilon, \delta, T \). By the assumptions on the initial condition, \( \mu(0) = 0 \) as long as \( \delta \geq \epsilon \).

Fix now \( \epsilon, \delta \) and choose \( k \sim \log \epsilon^{-1} \) so that \( \delta \geq \epsilon \). We can iterate inequality (3.15) for \( 2^{-k}, 2^{-k+1}, \ldots, 2^{-1}, \delta, \delta, \delta, \delta \) to obtain (recall that \( \mu(t) \leq 1 \))
\[ \mu(t) \leq \frac{(cT)^{k}}{k!} + T \sum_{j=0}^{k-1} \frac{(cT)^{j}}{(2^{-j})^{14}} \leq \frac{(cT)^{k}}{k!} + T \frac{\epsilon^{2m}}{\delta^{1+5m}} \epsilon^{k+30}. \]

If we choose \( \delta = \epsilon^{a} \) with \( a \) sufficiently small and \( k/(\log \epsilon^{-1}) \) sufficiently small, we can deduce that
\[ \mu(t) \leq \epsilon^{2m-14a}, \]
with \( c = c(T, a) \).

**Step 6.** Control of the velocity and conclusion. Let us compute the velocity outside the disc \( D_2 = B_{\epsilon^{a/4}}(c_\epsilon(t)) \) centred at \( c_\epsilon(t) \) and with radius \( \epsilon^{a/4} \). To this end let \( D_1 = B_{\epsilon^{a}}(c_\epsilon(t)) \). Fix \( x \in \overline{D_2} \) and let \( \tilde{n} \) be the unit vector in the direction \( c_\epsilon(t) - x \).

The velocity at \( x \) can be decomposed in three components: the first, \( u_{\epsilon 1} \), corresponds to the contribution of the pseudo-vorticity in \( D_1 \), the second, \( u_{\epsilon 2} \), corresponds to the contribution of the vorticity in \( D_2 \), and the third, \( u_{\epsilon 3} \), due to the external field.

Since \( \tilde{n} \cdot k_m(x - c_\epsilon(t)) = 0 \), by (3.14),
\[ |u_{\epsilon 1}(t, x) \cdot \tilde{n}| = \left| \int_{D_1} \tilde{n} \cdot (k_m(x - y) - k_m(x - c_\epsilon(t))) \theta_\epsilon(t, y) dy \right| \leq \frac{\epsilon^a}{\epsilon^{a(3-m)}} \int_{D_1} \theta_\epsilon(t, y) dy \leq \epsilon^{2m}. \]

Moreover, by the Hardy-Littlewood-Sobolev inequality, since \( \theta_\epsilon(t, y) \lesssim \epsilon^{-2} \) and
\[ \int_{D_1} \theta_\epsilon(t, y) dy = m_\epsilon(t) \lesssim \epsilon^{2m-14a}, \]
we have that,
\[ |u_{\epsilon 2}(t, x) \cdot \tilde{n}| \leq \int_{D_1} \left| \frac{1}{|x - y|^{3-m}} \theta_\epsilon(t, y) dy \right| \lesssim (\epsilon^{-2})^{1/2} (\epsilon^{2m-14a})^{1/2 (m-1)} = \epsilon^{m^2 - 3 - 7a(m-1)}. \]

We notice that the condition \( m > \sqrt{3} \) is only necessary here to ensure that \( u_{\epsilon 2}(t, x) \) is small. Finally, the velocity due to the external field is small by assumption.
3.4. Proof of Theorem 3.6. Given \( N \geq 2 \) and \( T > 0 \), fix intensities \( \gamma_1, \gamma_2, \ldots, \gamma_N \) and initial vortex positions \( x_1, x_2, \ldots, x_N \), so that the vortex motion (1.3) has a solution in \([0, T]\) without collisions. Therefore the number

\[
D = \min_{t \in [0, T], i \neq j} |X_i(t) - X_j(t)|,
\]

is positive. Consider \( \epsilon \ll D \), so that the initial blobs \((\theta_{0,j})_{j=1,2,\ldots,N}\) are disjoint (and separated by a distance comparable with \( D \)). We first consider the regularized equation (2.7) with regularisation size \( \delta \) also much smaller than \( D \), so that the regularisations of the initial blobs are still separated by a distance comparable with \( D \). We denote by \( \tilde{\theta}^\delta \) the solution to the regularized problem (here \( \epsilon \) refers to the parameter in the initial condition and \( \delta \) to the regularisation size).

It is not difficult to see that the supports of the regularized blobs remain disjoint (but not necessarily localized) using the diffeomorphisms (2.11) introduced in the proof of Proposition 2.4. Therefore we can single out the evolutions \((\tilde{\theta}_{\epsilon,j}^\delta)_{j=1,2,\ldots,N}\) such that \( \tilde{\theta}_{\epsilon,j}^\delta(0) \) is the regularisation of \( \theta_{0,j} \), to obtain for \( j = 1, 2, \ldots, N \),

\[
\begin{aligned}
\partial_t \tilde{\theta}_{\epsilon,j}^\delta + \nabla \cdot ((\tilde{u}_{\epsilon,j}^\delta + \tilde{F}_{\epsilon,j}) \tilde{\theta}_{\epsilon,j}^\delta) &= 0, \\
\tilde{u}_{\epsilon,j}^\delta &= k_{\epsilon,m} \ast \tilde{\theta}_{\epsilon,j}^\delta, \\
\tilde{F}_{\epsilon,j}^\delta &= \sum_{\ell \neq j} \tilde{u}_{\epsilon,\ell}^\delta.
\end{aligned}
\]

Proposition 3.8 obviously holds also for the regularized system above and shows that the blobs stay localized. In particular, if for each \( j \) we localize, at each time, the velocity field \( \tilde{F}_{\epsilon,j}^\delta \) generated by all other blobs around the support of \( \tilde{\theta}_{\epsilon,j}^\delta \), again with a size much smaller than \( D \), the evolution of each blob is unchanged.

In the limit as \( \delta \to 0 \), we obtain that the evolution of vortex blobs can be singled out to

\[
\begin{aligned}
\partial_t \theta_{\epsilon,j} + \nabla \cdot ((u_{\epsilon,j} + F_{\epsilon,j}) \theta_{\epsilon,j}) &= 0, \\
u_{\epsilon,j} &= k_{\epsilon,m} \ast \theta_{\epsilon,j}, \\
F_{\epsilon,j} &= \sum_{\ell \neq j} u_{\epsilon,\ell}.
\end{aligned}
\]

for each \( j = 1, 2, \ldots, N \). We can finally apply Proposition 3.8 to each blob, and this finally concludes the proof of the theorem.
