Introduction. Entanglement is a quintessential manifestation of quantum mechanics [1, 2]. The study of entanglement and its distribution reveals fundamental insights into the nature of quantum correlations [3], on the properties of many-body systems [4, 5], and on possibilities and limitations for quantum-enhanced technologies [6]. A particularly interesting feature of entanglement is known as monogamy [7], that is, the impossibility of sharing entanglement unconditionally across many subsystems of a composite quantum system.

In the clearest manifestation of monogamy, if two parties $A$ and $B$ with the same (finite) Hilbert space dimension are maximally entangled, then their state is a pure state $|\Phi_{AB}\rangle$ [8], and neither of them can share any correlation—let alone entanglement—with a third party $C$, as the only physically allowed pure states of the tripartite system $ABC$ are product states $|\Phi_{AB}\rangle \otimes |\Psi_{BC}\rangle$. Consider now the more realistic case of $A$ and $B$ being in a mixed, partially entangled state $\rho_{AB}$. It is then conceivable for more parties to get a share of such entanglement. Namely, a state $\rho_{AB}$ on a Hilbert space $\mathcal{H}_A \otimes \mathcal{H}_B$ is termed “$n$-shareable” with respect to subsystem $B$ if it admits a symmetric $n$-extension, i.e. a state $\rho'_{AB, B_1, \ldots, B_n}$ on $\mathcal{H}_A \otimes \mathcal{H}_{B_1} \otimes \cdots \otimes \mathcal{H}_{B_n}$ invariant under permutations of the subsystems $B_1, \ldots, B_n$ and such that the marginal state of $A$ and any $B_i$ amounts to $\rho_{AB}$. While even an entangled state can be shareable up to some number of extensions, a seminal result is that a state $\rho_{AB}$ is $n$-shareable for all $n \geq 2$ if and only if it is separable, that is, no entangled state can be infinitely-shareable [7] [9, 12]. This statement formalizes exactly the monogamy of entanglement (in an asymptotic setting), and has many important implications, including the equivalence between asymptotic quantum cloning and state estimation [13] [14], the emergence of objectivity in the quantum-to-classical transition [15], the security of quantum key distribution [16–19], and the study of frustration and topological phases in many-body systems [20–24].

Over the last two decades, the goal to formalize monogamy of entanglement in precise quantitative terms and for a finite number of parties attracted increasing interest. The concept of monogamy became synonymous with the validity of an inequality due to Coffman, Kundu and Wootters (CKW) [25]. Given any tripartite state $\rho_{ABC}$, and choosing a bipartite entanglement measure $E$, the CKW inequality reads

$$E_{A, B}(\rho_{ABC}) \geq E_{A, C}(\rho_{ABC}) + E_{A, B}(\rho_{ABC}) - E_{B, C}(\rho_{ABC})$$

with $\rho_{AB} = \text{Tr}_C[\rho_{ABC}]$ and $\rho_{AC} = \text{Tr}_B[\rho_{ABC}]$. Intuitively, Eq. (1) means that the sum of the individual pairwise entanglements between $A$ and each of the other parties $B$ or $C$ cannot exceed the entanglement between $A$ and the remaining parties grouped together. Eq. (1) was originally proven for arbitrary states of three qubits, adopting the squared concurrence as entanglement measure [25]. Variations of the CKW inequality and generalizations to $n$ parties have been established for a number of entanglement measures in discrete as well as continuous variable systems [26, 27–39]. In particular, the squashed entanglement [40] and the one-way distillable entanglement fulfill Eq. (1) in composite systems of arbitrary dimension [28]. Hybrid CKW-like inequalities involving entanglement and other forms of correlations have also been proven [28, 41], while measures of quantum correlations weaker than entanglement generally violate the CKW inequality [42]. To some extent, therefore, Eq. (1) does capture the spirit of monogamy as a distinctive property of entanglement.

The main problem with CKW inequalities, however, is that their validity is not universal, but rather depends on the specific choice of $E$. Perhaps counterintuitively, several prominent entanglement monotones, such as the entanglement of formation or the distillable entanglement [3, 43, 44], do not obey the constraint formalized by Eq. (1), unless one introduces ad hoc rescalings (see e.g. [45]). Since entanglement as a concept is monogamous in the $n$-shareability sense [7], one is led to raise the following key question: Should any valid entanglement measure be monogamous in a CKW-like sense?

In this Letter we address the question in general terms.
Given an entanglement measure \( E \), we shall say that it is monogamous if there exists a non-trivial function \( f : \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{\geq 0} \) such that the generalized monogamy relation

\[
E_{AB}(\rho_{ABC}) \geq f(E_{AB}(\rho_{AB}), E_{AC}(\rho_{AC})), \tag{2}
\]
is satisfied for any state \( \rho_{ABC} \) on any tripartite Hilbert space \( \mathcal{H}_A \otimes \mathcal{H}_B \otimes \mathcal{H}_C \). Recalling that \( E \) is an entanglement monotone (which in turn implies that it is non-increasing under partial traces), the function \( f \) in Eq. (2) is without loss of generality such that \( f(x, y) > \max(x, y) \). Thus, to give rise to a non-trivial constraint, we need \( f(x, y) > \max(x, y) \) for at least some range of values of \( x \) and \( y \). One might further impose that \( f(x, y) \) is monotonic in both its arguments, but we will not require this here. We will however require that \( f \) is continuous in general.

While the CKW form (1) of a monogamy relation (which is recovered for the particular choice \( f(x, y) = x + y \)) implicitly presumes some kind of additivity of the entanglement measure in question, our general form (2) transcends this and can be applied to recognize any entanglement measure \( E \) as de facto monogamous, based on the intuition that it should obey some trade-off between the values of \( E_{AB} \) and \( E_{AC} \) for a given \( E_{ABC} \), see Fig. 1. Oppositely, if the only possible choice in Eq. (2) were \( f(x, y) = \max(x, y) \), then the measure \( E \) would fail monogamy in the most drastic fashion: given a state \( \rho_{ABC} \), having \( E_{ABC} > 0 \) a priori would not imply that \( E_{AB} \) and \( E_{AC} \) have to constrain each other in the interval \([0, E_{ABC}]\).

Quite remarkably, we rigorously show in the following that the entanglement of formation \( E_F \) (43) and the relative entropy of entanglement \( E_R \) (46), which are two of the most important entanglement monotones for mixed states (3, 43), cannot satisfy a non-trivial monogamy relation in the sense of Eq. (2), with violations becoming generic (47) with increasing Hilbert space dimension. We further show that a whole class of additive entanglement measures, including the entanglement cost \( E_C \) (43-45) and the regularized relative entropy of entanglement \( E_R \) (46-49), also fail monogamy as captured by Eq. (2). The latter result is proven by a constructive argument which exploits the peculiar properties of the maximally antisymmetric state on \( \mathcal{C}^n \otimes \mathcal{C}^n \), which is \((n - 1)\)-shareable yet far from separable (51), and has hence been dubbed the ‘universal counterexample’ in quantum information theory (52).

Specifically, any additive entanglement measure which is geometrically faithful in the sense of being lower-bounded by a quantity with a sub-polynomial dimensional dependence on the antisymmetric state, cannot be monogamous in general.

Our analysis then reveals that entanglement measures divide into two main categories: monogamous (yet geometrically unfaithful) ones, like the squashed entanglement (28, 49), and geometrically faithful (yet non-monogamous) ones, like \( E_F, E_R \), and their regularizations. Finally, we show that this dilemma can be resolved if one relaxes the definition (2) to introduce monogamy relations for any fixed dimension of \( \mathcal{H}_A \otimes \mathcal{H}_B \otimes \mathcal{H}_C \). Explicitly, we prove that \( E_F \) and \( E_R \) are retrievable as monogamous for any finite dimension, by providing dimension-dependent choices of \( f \) in Eq. (2), which only reduce to the trivial one in the limit of infinite dimension.

**Result (1) Generic non-monogamy for entanglement of formation and relative entropy of entanglement.** We begin by defining the measures employed in our analysis (3, 43, 44, 48). The entanglement of formation \( E_F \) is the convex roof extension of the entropy of entanglement, \( E_F(\rho_{AB}) = \inf \sum p_i S(\rho_{AB})(\rho_{\psi_i} \langle \psi_i | \psi_i \rangle_{\rho_{\psi_i}}) \), where \( S(\rho) = -\text{Tr}[\rho \log \rho] \) is the von Neumann entropy, and \( \log \equiv \log_2 \). On the other hand, the relative entropy of entanglement \( E_R \) quantifies the distance from the set of separable states, \( E_R(\rho_{AB}) = \inf S(\rho_{AB}|\rho_{AB}) \), where the minimization is over all separable \( \sigma_{AB} \), and \( S(\rho||\sigma) = \text{Tr}[\rho \log \rho - \rho \log \sigma] \) is the relative entropy.

The fact that both \( E_F \) and \( E_R \) violate the CKW inequality (1) may be traced to their subadditivity, meaning that there exist states \( \rho_{AB} \) and \( \sigma_{AC} \) such that \( E(\rho_{AB} \otimes \sigma_{AC}) < E(\rho_{AB}) + E(\sigma_{AC}) \), with \( E \) denoting either \( E_F \) (53) or \( E_R \). We now show that these measures fail monogamy even in the general sense of Eq. (2). These results are based on random induced states, defined as follows. Given \( n, s \in \mathbb{N} \), a random mixed state \( \rho \) on \( \mathcal{C}^s \) is induced by \( \mathcal{C}^s \) if \( \rho = T_{\mathcal{C}^s}(|\psi\rangle \langle \psi|) \) for \( |\psi\rangle \) a uniformly distributed random pure state on \( \mathcal{C}^n \otimes \mathcal{C}^n \). Note that if \( s \leq n \), this is equivalent to \( \rho \) being uniformly distributed on the set of mixed states of rank at most \( s \) on \( \mathcal{C}^s \). Here we focus on the (balanced) bipartite Hilbert space \( \mathcal{C}^s \otimes \mathcal{C}^s \), and aim to determine, given \( d, s \in \mathbb{N} \), what is the typical value of \( E_F(\rho_{AB}) \) and \( E_R(\rho_{AB}) \) for \( \rho_{AB} \) a random state on \( \mathcal{C}^s \otimes \mathcal{C}^s \) induced by an environment \( \mathcal{C}^t \). The answer is as follows,

\[
\mathbb{P} \left( E_F(\rho_{AB}) < \log d - \frac{1}{2} \log d \right) \leq t \leq 1 - e^{-c d^2 / \log^2 d},
\]

\[
\mathbb{P} \left( E_R(\rho_{AB}) < \log \left( \frac{s}{d} \right) + \frac{1}{2} \log \frac{s}{d} \right) \leq t \leq 1 - e^{-c d^2},
\]

where \( s \leq C d^2 / \log^2 (1/t) \) for any fixed \( t > 0 \) in Eq. (3), and \( C d / \log (1/t) / d^2 \leq s \leq d^2 \) for any fixed \( 0 < t < 1 \) in Eq. (4), while \( c, C > 0 \) denote universal constants in both equations. While Eq. (4) was established in (47) (Theorem V.1), although with a looser dependence on the parameters, Eq. (4) is an entirely original result of independent interest. Both proofs are mathematically quite involved, and are relegated to (55).
Importantly, failure of monogamy is then retrieved as a **generic** trait of entanglement quantified by these measures. Namely, the main result of this section is that there exist states $\rho_{ABC}$ on Hilbert spaces $H_A^{(i)} \otimes H_B^{(j)} \otimes H_C^{(k)}$ such that, as $x \to \infty$,

$$E_{A,B}(\rho_{ABC}^{(i,j,k)}) \leq x, \text{ while } E_{A,B}(\rho_{ABC}^{(i,j,k)}) \sim E_{A,C}(\rho_{ABC}^{(i,j,k)}) \sim x,$$  

for $E$ denoting either $E_F$ or $E_R$. To sketch the proof [53], set $d = [2^n]$ and $H_A^{(i)} \equiv H_B^{(j)} \equiv H_C^{(k)} \equiv C^d$. Next, consider $\rho_{ABC}^{(i,j,k)}$, a random state on $H_A^{(i)} \otimes H_B^{(j)} \otimes H_C^{(k)}$, induced by some $H_E^{(i)} \equiv C^s$, with $s \sim \log d$. In that way, $\rho_{AB}^{(i,j)}$ and $\rho_{AC}^{(i,k)}$ are random states on $C^d \otimes C^d$, induced by some $C' \otimes C'$, with $s \sim \log d$ satisfying both the conditions for Eqs. (9) and (10) to apply. We then have: $E_{F(R)}(\rho_{ABC}^{(i,j,k)}) \leq \log d \leq x$, while $E_{F(R)}(\rho_{AB}^{(i,j)})$ and $E_{F(R)}(\rho_{AC}^{(i,k)})$ are both equal to $\log d - O(1) \sim \log d \sim x$ with probability greater than $1 - 2e^{-cd\log d}$, and $E_{F(R)}(\rho_{AB}^{(i,j)})$ and $E_{F(R)}(\rho_{AC}^{(i,k)})$ are both equal to $\log d - \log(\log d) - O(1) \sim \log d \sim x$ with probability greater than $1 - 2e^{-cd\log d}$.

**Result (2) Non-monogamy for a whole class of additive entanglement measures.** We now show that a class of additive entanglement measures also fail monogamy in the sense of Eq. (2). A key role in this result is played by the antisymmetric state, defined as $[48, 51]$. Given a subsystem $A$ with (finite-dimensional) Hilbert space $H_A$, the (maximally) antisymmetric state $\alpha_A^{(i)}$ on $H_A^{(i)}$ is the normalized projector onto the antisymmetric subspace of $H_A^{(i)}$. A crucial property of $\alpha_A^{(i)}$ is that its reduced state on any group of $k$ subsystems, for any $0 < k < n$, is $\alpha_A^{(i)}$, i.e. the antisymmetric state on $H_A^{(i)}$.

We now focus on entanglement monotones $E$ satisfying the following conditions: (a) Normalization: For any state $\rho_{AB}$ on $H_A \otimes H_B$, $E_{A,B}(\rho_{AB}) = \min(\log d_A, \log d_B)$; (b) Lower-boundedness on the bipartite antisymmetric state: Denoting by $\alpha_{AB}$ the antisymmetric state on $H_A \otimes H_B$, (with $d_A = d_B$), $E_{A,B}(\alpha_{AB}) \geq c(\log d_A^2)$, where $c, t > 0$ are universal constants; (c) Additivity on product states: For any state $\rho_{AB}$ on $H_A \otimes H_B$, $E_{A,B}(\rho_{AB}^{(i,j)}) = m E_{A,B}(\rho_{AB})$; (d) Linearity on mixtures of locally orthogonal states: For any $0 < \lambda \leq 1$, and any states $\rho_{AB}, \sigma_{AB}$ on $H_A \otimes H_B$ such that $\text{Tr}[\rho_{AB}\sigma_{AB}] = \text{Tr}[\rho_{AB}\sigma_{AB}] = 0$, $E_{A,B}(\lambda \rho_{AB} + (1 - \lambda) \sigma_{AB}) = \lambda E_{A,B}(\rho_{AB}) + (1 - \lambda) E_{A,B}(\sigma_{AB})$.

Important examples of entanglement measures fulfilling the above requirements are the regularized versions of the entanglement of formation (aka entanglement cost) $E_{F}^{(i)}$ [43] and of the relative entropy of entanglement $E_{R}^{(i)}$ [49,50]. Indeed, condition (c) holds by construction for any regularized entanglement measure, defined as $E_{F,R}^{(i)}(\rho_{AB}) = \lambda \frac{1}{m} E_{F,R}^{(i,j)}(\rho_{AB}^{(i,j)})$. Furthermore, in the case of $E_{F}^{(i)}$ and $E_{R}^{(i)}$, conditions (a) and (d) are inherited as they hold for $E_{F}$ and $E_{R}$. Finally, condition (b) can be seen as some kind of faithfulness (or geometry-preserving) property: given that the antisymmetric state has constant trace distance from the set of separable states, one may wish for an entanglement measure to stay bounded away from 0 on the antisymmetric state, dimension-independently as well (or with a sub-polynomial dependence). For $E$ being $E_{F}^{(i)}$ or $E_{R}^{(i)}$, a condition stronger than (b) in fact holds, namely $E_{A,A}(\alpha_{AB}) \geq c$, where $c > 0$ is a universal constant [51].

What we show here is that any entanglement measure $E$, obeying properties (a)–(d), cannot satisfy a non-trivial monogamy relation in the sense of Eq. (2). We first establish the following result. Let $n \in \mathbb{N}$, $d = 2^n + 1$, and set $H_A \equiv C^d$. Assume next that $E$ satisfies conditions (a) and (b). Then, there exists $0 \leq k < n - 1$ such that

$$E_{A_1,A_2} \cdots A_{k+1} \alpha_{A^{2\cdots k+1}} = E_{A_1,A_2} \cdots A_{k+1} \alpha_{A^{2\cdots k+1}} > (1 - \frac{\ln(d)/\pi}{n})E_{A_1,A_2} \cdots A_{k+1} \alpha_{A^{2\cdots k+1}}.$$  

To prove Eq. (6), consider a partition of the antisymmetric state $\alpha_{A^{2\cdots k+1}}$ as illustrated in Fig. 2 and set $g_k = E_{A_1,A_2} \cdots A_{k+1} \alpha_{A^{2\cdots k+1}}$ for each $0 \leq k < n$. Then,

$$\frac{c}{n^t} = \frac{c}{(\log d)}^t \Rightarrow g_0 \leq g_1 \leq \cdots \leq g_{r+1} \leq g_n \leq \log d = n.$$  

The last inequality is by property (a), because $d_{g_k} = 2^n + 1$. The first inequality is by property (b), because $g_0 = g_1 = g_{n+1}$ is $c(\log d)^t \div c/n^t$. And the middle inequalities are by monotonicity of $E$ under discarding of subsystems, because for each $0 \leq k < n - 1, \alpha_{A_1,A_2} \cdots A_{k+1}$ is the reduced state of $\alpha_{A_1,A_2} \cdots A_{k+1}$. Now, Eq. (7) implies that there exists $0 < r < n - 1$ such that $g_r / g_{r+1} > 1 - \ln(n+1)/c\pi R$. Indeed, otherwise we would have $\pi = \frac{\sum_{k=0}^{n-1} g_k}{g_n} < (1 - \frac{\ln(d)/\pi}{n}) \frac{n}{2\pi}$, which contradicts Eq. (7). Then, as we have on one hand $g_{r+1} = E_{A_1,A_2} \cdots A_{r+1} \alpha_{A^{2\cdots r+1}}$, and on the other hand $g_k = E_{A_1,A_2} \cdots A_{k+1} \alpha_{A^{2\cdots k+1}}= E_{A_1,A_2} \cdots A_{k+1} \alpha_{A^{2\cdots k+1}}$, Eq. (6) is proven.

The main result of this section then follows immediately. Namely, once again, there exist states $\rho_{ABC}$ on Hilbert spaces $H_A^{(i)} \otimes H_B^{(j)} \otimes H_C^{(k)}$ such that Eq. (5) holds, for $E$ now denoting any entanglement measure satisfying conditions (a)–(d).

The proof goes as follows. As $E$ satisfies (a) and (b), we know by Eq. (9) that, for any $d \in \mathbb{N}$, there exists a state $\rho_{ABC}$ on $H_A \otimes H_B \otimes H_C$, where $H_A \equiv C^d$ and $H_B \equiv H_C \equiv C^{d^2}$ for some $0 < k \leq \log d$ (see Fig. 2), such that $E_{A,B}(\rho_{AB})$ and $E_{A,C}(\rho_{AC})$ are both lower bounded by

$$\left(1 - \frac{\log(d)/\pi}{n}\right) E_{A,B,C}(\rho_{ABC}) = (1 - o(1)) E_{A,B,C}(\rho_{ABC}).$$  

Now, by property (c), for any $m \in \mathbb{N}$, considering $\rho_{ABC}^{(m)}$ instead of $\rho_{ABC}$ (and relabelling $A^{(m)}$ into $A$ etc.) will multiply all values of $E$ by a factor $m$. By property (d), for any $0 \leq \lambda \leq 1$ and any separable state $\sigma_{ABC}$ (across the cut $A : BC$) which is locally orthogonal to $\rho_{ABC}$, considering $\lambda \rho_{ABC} + (1 - \lambda) \sigma_{ABC}$ instead of $\rho_{ABC}$ will multiply all values of $E$ by a factor $\lambda$. Consequently, any value $x > 0$ for $E_{A,B,C}(\rho_{ABC})$ is indeed attainable, on some suitably large Hilbert space $H_A^{(i)} \otimes H_B^{(j)} \otimes H_C^{(k)}$. □

Recapturating, we demonstrated that entanglement measures which faithfully capture the properties of the antisymmetric state cannot be monogamous in general. Conversely, there exist relevant entanglement measures for which the desirable condition (b) does not hold—such as the squashed
entanglement, which scales as $o(1/d_A)$ on the antisymmetric state $\sigma_{A'V}$—yet monogamy holds instead, even in the original CKW form [1] [28-30]. This is the origin of the “monogamy vs faithfulness” dilemma discussed in the introduction.

**Result (3) Recovering monogamy: dimension-dependent relations.** In the previous two sections, we proved that several important entanglement measures cannot obey a monogamy relation of the form (2) with $f$ a universal function. Nevertheless, it may become possible to establish such an inequality if we allow the function $f$ to be dimension-dependent. For instance, the squared entanglement of formation obeys the CKW inequality for arbitrary three-qubit states [36], which means that choosing $f(x, y) = \sqrt{x^2 + y^2}$ in Eq. (2), as depicted in Fig. 1 (dotted boundary), makes $E_F$ monogamous when restricted to Hilbert spaces with $d_A = d_B = d_C = 2$.

The third main result of this Letter is to show that non-trivial dimension-dependent monogamy relations can be established for $E_F$ and $E_F^\infty$ in any finite dimension. Concretely, for any state $\rho_{ABC}$ on a Hilbert space $\mathcal{H}_A \otimes \mathcal{H}_B \otimes \mathcal{H}_C$, it holds

$$E_F(\rho_{ABC}) \geq \max \left\{ E_F(\rho_{AB}) + \frac{c}{d_A d_B \log d_C} E_F(\rho_{AC})^8, E_F(\rho_{AC}) + \frac{c}{d_A d_C \log d_B} E_F(\rho_{AB})^8 \right\}, \quad (8a)$$

$$E_R(\rho_{ABC}) \geq \max \left\{ E_R(\rho_{AB}) + \frac{c'}{d_A d_B \log d_C} E_R(\rho_{AC})^4, E_R(\rho_{AC}) + \frac{c'}{d_A d_C \log d_B} E_R(\rho_{AB})^4 \right\}, \quad (8b)$$

where $c, c' > 0$ are universal constants, and we set $d_A B = \min\{d_A, d_B\}, d_A C = \min\{d_A, d_C\}$. An instance of Eq. (85) is qualitatively illustrated in Fig. 1 (dot-dashed boundary).

The proof of Eqs. (8) makes use of results from Refs. 50, 55-58, and is provided in [55]. While Eqs. (8) may not be tight [55], they do establish that the involved entanglement measures can be effectively regarded as monogamous according to Eq. (2) in any finite dimension, even though the constraints become trivial in the limit of infinite dimension, in agreement with results (1) and (2). Notice further that Eqs. (8) encapsulate strict monogamy, as the constraining functions satisfy $f(x, y) > \max(x, y)$ for all positive $x$ and $y$. This implies that if, say, $E_F(\rho_{AB}) = E_F(\rho_{AC})$, then $E_F(\rho_{AC}) = 0$ for $E$ being either $E_F$ or $E_F^\infty$, which means that $A$ and $C$ must be unentangled, as both measures vanish only on separable states.

**Conclusions.** We addressed on general grounds the question of whether entanglement measures should be monogamous in the sense of obeying a quantitative constraint akin to Eq. (1) introduced in [25]. We showed that paradigmatic measures such as the entanglement of formation and the relative entropy of entanglement, as well as their regularizations, cannot be monogamous in general, as they cannot satisfy any non-trivial general relation of the form (2) limiting the distribution of bipartite entanglement in arbitrary tripartite states. Monogamy can nonetheless be recovered if the constraints are made dependent on the (finite) dimension of the system.

The present study substantially advances our understanding of entanglement and the complex laws governing its distribution in systems of multiple parties, and paves the way to more practical developments in quantum communication and computation. The concept of monogamy as studied here is of particular physical relevance, as the structure of Eq. (4) lends itself to be applied repeatedly to establish limitations in a many-body scenario [5], allowing one to compare the distribution of entanglement on equal footing across the various parts of a composite system, unlike e.g. the case of hybrid monogamy relations involving different quantifiers [28].

It will be worth investigating further links between the phenomenon of monogamy and the so-called quantum marginal problem [59] as well as the fact that information cannot be arbitrarily distributed in multipartite quantum states [60-63]. Implications of our study for progress in other fields like condensed matter [5] and cosmology [54], where monogamy of entanglement takes centre stage, also deserve further study.

Should Entanglement Measures be Monogamous or Faithful?

APPENDIX A: ENTANGLEMENT OF FORMATION AND RELATIVE ENTROPY OF ENTANGLEMENT OF RANDOM STATES

Let us first fix a few definitions and notations. For any \( n \in \mathbb{N} \) and \( 1 \leqslant p \leqslant \infty \), we denote by \( \| \cd \|_p \) the Schatten-\( p \)-norm on the set of Hermitian operators on \( \mathbb{C}^n \). Particular instances of interest are the trace-class norm \( \| \cd \|_1 \), the Hilbert–Schmidt norm \( \| \cd \|_2 \) and the operator norm \( \| \cd \|_\infty \).

Given \( n, s \in \mathbb{N} \), we say that a random mixed state \( \rho \) on \( \mathbb{C}^n \) is induced by \( \mathbb{C}^s \), which we denote by \( \rho \sim \mu_{n,s} \), if \( \rho = \text{Tr}_{C^s} |\psi\rangle\langle \psi| \) for \( |\psi\rangle \) a uniformly distributed random pure state on the global “system + ancilla” space \( \mathbb{C}^n \otimes \mathbb{C}^s \). It is known that in the case \( s \ll n, \rho \sim \mu_{n,s} \) is equivalent to \( \rho \) being uniformly distributed (for the measure induced by the Hilbert–Schmidt distance) on the set of mixed states of rank at most \( s \) on \( \mathbb{C}^n \) (see e.g. [65]). In the sequel, we shall use the following shorthand notation: for any pure state \( \psi \) on \( \mathbb{C}^n \otimes \mathbb{C}^s \), \( \rho_\psi \) stands for the corresponding marginal state on \( \mathbb{C}^n \), i.e. \( \rho_\psi = \text{Tr}_{C^s} |\psi\rangle\langle \psi| \).

In the following we will always work on the bipartite Hilbert space \( \mathbb{C}^d \otimes \mathbb{C}^d \), where we denote by \( D(\mathbb{C}^d \otimes \mathbb{C}^d) \) the set of all states and by \( S(\mathbb{C}^d : \mathbb{C}^d) \) the set of states which are separable across the cut \( \mathbb{C}^d : \mathbb{C}^d \). For any \( \rho \in D(\mathbb{C}^d \otimes \mathbb{C}^d) \), its entanglement of formation is defined as

\[
E_F(\rho) = \inf \left\{ \sum_i p_i S(\rho_{\psi_i}) : \rho = \sum_i p_i |\psi_i\rangle\langle \psi_i|, \quad p_i \geqslant 0, \quad \sum p_i = 1, \quad |\psi_i\rangle \in \mathbb{C}^d \otimes \mathbb{C}^d \right\},
\]

and its relative entropy of entanglement as

\[
E_R(\rho) = \inf \left\{ S(\rho||\sigma) : \sigma \in S(\mathbb{C}^d : \mathbb{C}^d) \right\} = \inf \left\{ \text{Tr}(\rho (\log \rho - \log \sigma)) : \sigma \in S(\mathbb{C}^d : \mathbb{C}^d) \right\}.
\]

We are interested in determining, given \( d, s \in \mathbb{N} \), what is the typical value of \( E_F(\rho) \) and \( E_R(\rho) \) for \( \rho \sim \mu_{d,d,s} \). The answer is stated in Theorems 1 and 2 below. They both rely on technical lemmas appearing in Section A1. Theorem 1 is then obtained as a direct corollary of Proposition 8. While Theorem 2 follows from the upper bound of Proposition 10 and the lower bound of Proposition 13. Let us also emphasize that the statement about the typical value of \( E_F \), appearing in Theorem 1, was already more or less established in [47, Thm. V.1], but only the lower bound appears there and with a not as tight dependence in the parameters, which is why we briefly repeat the whole argument here. Oppositely, the statement about the typical value of \( E_R \), appearing in Theorem 2, is new.

**Theorem 1.** Fix \( t > 0 \). Let \( \rho \) be a random state on \( \mathbb{C}^d \otimes \mathbb{C}^d \) induced by some environment \( \mathbb{C}^s \), with \( s \ll d^2 / \log^2 d \) for some universal constant \( C > 0 \). Then,

\[
\mathbb{P} \left( \left| E_F(\rho) - \frac{1}{2 \ln 2} \log d - \frac{1}{2 \ln 2} \right| \leqslant t \right) \geqslant 1 - e^{-c d^2 / \log^2 d},
\]

where \( c > 0 \) is a universal constant.

**Theorem 2.** Fix \( 0 < t < 1 \). Let \( \rho \) be a random state on \( \mathbb{C}^d \otimes \mathbb{C}^d \) induced by some environment \( \mathbb{C}^s \), with \( C d \log(1/t) / t^2 \ll s \ll d^2 \) for some universal constant \( C > 0 \). Then,

\[
\mathbb{P} \left( \left| E_R(\rho) - 2 \log d - \log s - \frac{1}{2 \ln 2} \frac{s}{d^2} \right| \leqslant t \right) \geqslant 1 - e^{-c w^2},
\]

where \( c > 0 \) is a universal constant.

### 1. A few technical lemmas

The two crucial tools that we will use in order to obtain Theorems 1 and 2 are Levy’s Lemma and Dvoretzky’s Theorem (the former being at the heart of the derivation of the latter). These guarantee that, in high dimension, regular enough functions typically do not deviate much from their average behaviour. The precise version of this general paradigm that we will need are quoted in the following Lemmas 3 and 4.
Lemma 3 (Levy’s Lemma for Lipschitz functions on the sphere \([66]\)). Let \(n \in \mathbb{N}\). For any \(L\)-Lipschitz function \(f : S^{\mathbb{C}} \to \mathbb{R}\) and any \(t > 0\), if \(\psi\) is uniformly distributed on \(S^{\mathbb{C}}\), then
\[
P(|f(\psi) - \mathbb{E}f| > t) \leq e^{-cnt^2/L^2},
\]
where \(c > 0\) is a universal constant.

Lemma 4 (Dvoretzky’s Theorem for Lipschitz functions on the sphere \([67, 68]\)). Let \(n \in \mathbb{N}\). For any \(L\)-Lipschitz function \(f : S^{\mathbb{C}} \to \mathbb{R}\) and any \(t > 0\), if \(H\) is a uniformly distributed \(Cnt^2/L^2\)-dimensional subspace of \(\mathbb{C}^n\), with \(C > 0\) a universal constant, then
\[
P(\exists \psi \in H \cap S^{\mathbb{C}} : |f(\psi) - \mathbb{E}f| > t) \leq e^{-cnt^2/L^2},
\]
where \(c > 0\) is a universal constant.

For the sake of completeness, we now re-derive (more or less well-known) concentration results for two functions that will pop up later on while establishing Theorems \(1\) and \(2\).

Lemma 5. Fix \(n, s \in \mathbb{N}\) with \(s \leq n\) and \(t > 0\). If \(\psi\) is uniformly distributed on \(S^{\mathbb{C}\otimes\mathbb{C}}\), then
\[
P\left(\left|S(\rho_{\psi}) - \log s + \frac{1}{2} \frac{s}{\ln 2} n\right| > t\right) \leq e^{-cnt^2/\log^2 n},
\]
where \(c > 0\) is a universal constant.

Proof. Define the function \(f : \psi \in S^{\mathbb{C}\otimes\mathbb{C}} \mapsto S(\rho_{\psi}) \in \mathbb{R}\). We know from \([47]\) Lemma III.2, that \(f\) is \(3\log n\)-Lipschitz. Besides, we also know from \([47]\) Lemma II.4, that \(f\) has average (w.r.t. the uniform probability measure over \(S^{\mathbb{C}\otimes\mathbb{C}}\))
\[
\mathbb{E}_\psi f(\psi) = \log s - \frac{1}{2} \frac{s}{\ln 2} + o\left(\frac{s}{n}\right).
\]
Having at hand these two estimates, Lemma 5 is a direct consequence of Levy’s Lemma 3.

Lemma 6. Fix \(d \in \mathbb{N}\) and \(t > 0\). If \(H\) is a uniformly distributed \(Cd^2t^2/\log^2 d\)-dimensional subspace of \(\mathbb{C}^d \otimes \mathbb{C}^d\), with \(C > 0\) a universal constant, then
\[
P\left(\exists \psi \in H \cap S^{\mathbb{C}\otimes\mathbb{C}} : \left|S(\rho_{\psi}) - \log d + \frac{1}{2} \frac{s}{\ln 2} n\right| > t\right) \leq e^{-cnt^2/\log^2 d}.
\]

Proof. Define the function \(f : \psi \in S^{\mathbb{C}\otimes\mathbb{C}} \mapsto S(\rho_{\psi}) \in \mathbb{R}\). We know from \([47]\) Lemma III.2, that \(f\) is \(3\log d\)-Lipschitz. Besides, we also know from \([47]\) Lemma II.4, that \(f\) has average (w.r.t. the uniform probability measure over \(S^{\mathbb{C}\otimes\mathbb{C}}\))
\[
\mathbb{E}_\psi f(\psi) = \log d - \frac{1}{2} \frac{s}{\ln 2} + o(1).
\]
Having at hand these two estimates, Lemma 6 is a direct consequence of Dvoretzky’s Theorem 4.

Lemma 7. Fix \(n, s \in \mathbb{N}\) with \(s \leq n\), as well as \(x \in S^{\mathbb{C}}\). and let \(\rho\) be a random state on \(\mathbb{C}^n\) induced by an environment \(\mathbb{C}^n\). Then,
\[
\forall t > 0, \ P\left(\left|\sqrt{\langle \psi | x \rangle} - \frac{1}{\sqrt{n}}\right| > \frac{t}{\sqrt{n}}\right) \leq e^{-cnt^2},
\]
where \(c > 0\) is a universal constant.

Proof. Define the function \(g : \psi \in S^{\mathbb{C}\otimes\mathbb{C}} \mapsto \sqrt{\langle \psi | x \rangle}\). We know from \([68]\) App. B, that \(g\) is 1-Lipschitz. Besides, we also know from \([68]\), Appendix B, that \(g\) has average (w.r.t. the uniform probability measure over \(S^{\mathbb{C}\otimes\mathbb{C}}\))
\[
\mathbb{E}_\psi g(\psi) = \frac{1}{\sqrt{n}} + o\left(\frac{1}{\sqrt{n}}\right).
\]
Having at hand these two estimates, the conclusion of Lemma 7 is a direct consequence of Levy’s Lemma 3.
2. Typical value of the entanglement of formation of random induced states

**Proposition 8.** Fix \( t > 0. \) Let \( \rho \) be a random state on \( \mathbb{C}^d \otimes \mathbb{C}^d, \) induced by some environment \( \mathbb{C}^s, \) with \( s \leq Cd^2 \log^2 d \) for some universal constant \( C > 0. \) Then,

\[
\mathbb{P}\left( 3 \varphi \in \text{supp}(\rho) \cap S_{\mathbb{C}^d \otimes \mathbb{C}^d} : \left| S(\rho) - \log d + \frac{1}{\ln 2} \right| > t \right) \leq e^{-c d^2 s^2 / \log^2 d},
\]

where \( c > 0 \) is a universal constant.

**Proof.** One simply has to observe that \( \text{supp}(\rho) \) is a uniformly distributed \( s \)-dimensional subspace of \( \mathbb{C}^d \otimes \mathbb{C}^d, \) and apply Lemma \( \text{6} \) □

3. Upper and lower bounds on the typical relative entropy of entanglement of random induced states

Observe the following alternative form of the relative entropy of entanglement: For a state \( \rho \) on \( \mathbb{C}^d \otimes \mathbb{C}^d, \)

\[
E_R(\rho) = \min \left\{ -\text{Tr}(\rho \log \sigma) : \sigma \in S(\mathbb{C}^d : \mathbb{C}^d) \right\} - S(\rho). \tag{A3}
\]

**Lemma 9.** For any state \( \rho \) on \( \mathbb{C}^d \otimes \mathbb{C}^d, \) we have

\[
E_R(\rho) \leq 2 \log d - S(\rho).
\]

**Proof.** It is clear from equation \( \text{(A3)} \) that we have, in particular,

\[
E_R(\rho) \leq -\text{Tr}(\rho \log \frac{1d}{d^2}) - S(\rho) = 2 \log d - S(\rho).
\]

This concludes the proof of Lemma \( \text{9} \) □

**Proposition 10.** Fix \( 0 < t < 1. \) Let \( \rho \) be a random state on \( \mathbb{C}^d \otimes \mathbb{C}^d, \) induced by some environment \( \mathbb{C}^s, \) with \( s \leq d^2. \) Then,

\[
\mathbb{P}\left( E_R(\rho) > 2 \log d - \log s + \frac{1}{2 \ln 2} \frac{s}{d^2} + t \right) \leq e^{-c d^2 s^2 / \log^2 d},
\]

where \( c > 0 \) is a universal constant.

**Remark 11.** Note that the bound appearing in Proposition \( \text{10} \) is non-trivial only in the regime \( d \ll s \ll d^2. \) Indeed, it also holds for any state \( \rho \) on \( \mathbb{C}^d \otimes \mathbb{C}^d \) that \( E_R(\rho) \leq E_F(\rho) \leq d \log d, \) and if \( s < d, \) we do not learn anything better than that from Proposition \( \text{10} \) for a random state \( \rho \) on \( \mathbb{C}^d \otimes \mathbb{C}^d, \) induced by some environment \( \mathbb{C}^s. \) Hence in words, Proposition \( \text{10} \) actually tells us the following: if \( \rho \sim \mu_{\mathbb{C}^s}, \) with \( d \ll s \ll d^2, \) then \( E_R(\rho) \) is w.h.p. smaller than \( 2 \log d - \log s + O(s / d^2), \) as \( d, s \to \infty. \)

**Proof.** From Lemma \( \text{9} \) it is clear that, for any \( 0 < t < 1, \)

\[
\mathbb{P}\left( E_R(\rho) > 2 \log d - \log s + \frac{1}{2 \ln 2} \frac{s}{d^2} + t \right) \leq \mathbb{P}\left( S(\rho) < \log s - \frac{1}{2 \ln 2} \frac{s}{d^2} - t \right). \tag{A4}
\]

Now, we know from Lemma \( \text{8} \) that the probability on the r.h.s. of inequality \( \text{(A4)} \) is smaller than \( e^{-c d^2 s^2 / \log^2 d}, \) which is precisely the announced result. □

**Lemma 12.** For any state \( \rho \) on \( \mathbb{C}^d \otimes \mathbb{C}^d, \) we have

\[
E_R(\rho) \geq - \log \left( \max \{(x \otimes y)\rho(x \otimes y) : x, y \in S_{\mathbb{C}^d} \} \right) - S(\rho).
\]

**Proof.** We see from equation \( \text{(A3)} \) that the only thing we have to prove is that

\[
\min \left\{ -\text{Tr}(\rho \log \sigma) : \sigma \in S(\mathbb{C}^d : \mathbb{C}^d) \right\} \geq - \log \left( \max \{(x \otimes y)\rho(x \otimes y) : x, y \in S_{\mathbb{C}^d} \} \right). \tag{A5}
\]

Now, for any \( \sigma \in S(\mathbb{C}^d : \mathbb{C}^d), \) we see by concavity of \( \log \) that

\[
- \text{Tr}(\rho \log \sigma) \geq - \log \left( \sum_{i=1}^{d^2} \langle e_i | \rho | e_i \rangle \log \langle e_i | \rho | e_i \rangle \right) = \log \text{Tr}(\rho \sigma).
\]

This concludes the proof of Lemma \( \text{12} \) □
As a consequence,
\[ \min \left\{ - \Tr(\rho \log \sigma) : \sigma \in \mathcal{S}(\mathbb{C}^d : \mathbb{C}^d) \right\} \geq \min \left\{ - \log \Tr(\rho \sigma) : \sigma \in \mathcal{S}(\mathbb{C}^d : \mathbb{C}^d) \right\} = - \log \left( \max \left\{ \Tr(\rho \sigma) : \sigma \in \mathcal{S}(\mathbb{C}^d : \mathbb{C}^d) \right\} \right) . \]

It then follows from extremality of pure separable states amongst all separable states that
\[ \max \left\{ \Tr(\rho \sigma) : \sigma \in \mathcal{S}(\mathbb{C}^d : \mathbb{C}^d) \right\} = \max \left\{ \langle x \otimes y | \rho | x \otimes y \rangle : x, y \in S_{\mathbb{C}^d} \right\} , \]
so that equation (A5) indeed holds. \qed

**Proposition 13.** Fix \( 0 < t < 1 \). Let \( \rho \) be a random state on \( \mathbb{C}^d \otimes \mathbb{C}^d \) induced by some environment \( \mathbb{C}^t \), with \( Cd \log(1/t)/t^2 \leq s \leq d^2 \) for some universal constant \( C > 0 \). Then,
\[ \mathbb{P} \left( E_g(\rho) < 2 \log d - \log s + \frac{1}{2 \ln 2 \, d^2} - t \right) \leq e^{-c^3 \ln^3 d} , \]
where \( c > 0 \) is a universal constant.

**Remark 14.** Note that Proposition [13] actually tells us the following: if \( \rho \sim \mu_{d, s} \) with \( d \ll s \ll d^2 \), then \( E_g(\rho) \) is w.h.p. bigger than \( 2 \log d - \log s - o(1) \), as \( d, s \to +\infty \). And in the case of sufficiently mixed states, the refinement: if \( \rho \sim \mu_{d, s} \) with \( d^{1/3} \ll s \ll d^2 \), then \( E_g(\rho) \) is w.h.p. bigger than \( 2 \log d - \log s - O(s/d^2) \), as \( d, s \to +\infty \). That is, in that regime, the fluctuations from \( 2 \log d - \log s \) are of the same order \( \pm O(s/d^2) \), cf. Remark [17]. We conjecture that for \( 1 \leq s \leq O(d) \), w.h.p. \( E_g(\rho) \geq \log d - O(1) \).

**Proof.** Set \( M(\rho) = \max \{ \langle x \otimes y | \rho | x \otimes y \rangle : x, y \in S_{\mathbb{C}^d} \} \). From Lemma [12] it is clear that, for any \( 0 < t < 1 \),
\[ \mathbb{P} \left( E_g(\rho) < 2 \log d - \log s + \frac{1}{2 \ln 2 \, d^2} - t \right) \leq \mathbb{P} \left( - \log M(\rho) < 2 \log d - t \right) + \mathbb{P} \left( S(\rho) > \log s - \frac{1}{2 \ln 2 \, d^2} + t \right) . \]

Indeed, defining the events \( \mathcal{A} = \{ E_g(\rho) < 2 \log d - \log s + 1/(2 \ln 2) s/d^2 + t \} \) and \( \mathcal{B}_1 = \{ - \log M(\rho) < 2 \log d - t/2 \} \), \( \mathcal{B}_2 = \{ S(\rho) > \log s - 1/(2 \ln 2) s/d^2 + t/2 \} \), we have \( \neg \mathcal{B}_1 \cap \neg \mathcal{B}_2 \Rightarrow \neg \mathcal{A} \), i.e. equivalently \( \mathcal{A} \Rightarrow \mathcal{B}_1 \cup \mathcal{B}_2 \). Hence,
\[ \mathbb{P}(\mathcal{A}) \leq \mathbb{P}(\mathcal{B}_1 \cup \mathcal{B}_2) \leq \mathbb{P}(\mathcal{B}_1) + \mathbb{P}(\mathcal{B}_2) . \]

Now on the one hand, we know from Lemma [5] that
\[ \mathbb{P} \left( S(\rho) > \log s - \frac{1}{2 \ln 2 \, d^2} + t \right) \leq e^{-c d^2 d^2 / \log^2 d} . \]

And on the other hand, one may observe that
\[ \mathbb{P} \left( - \log M(\rho) < 2 \log d - t \right) = \mathbb{P} \left( \sqrt{M(\rho)} > \frac{e^{t/4}}{d} \right) \leq \mathbb{P} \left( \sqrt{M(\rho)} > \frac{1 + t/4}{d} \right) . \]

So fix \( 0 < \delta < 1/8 \) and consider \( N_{d, \delta} \) a \( \delta \)-net for \( \| \cdot \| \) within \( S_{\mathbb{C}^d} \). By a standard volumetric argument (see e.g. [69, Ch. 4]) we know that we can impose \( |N_{d, \delta}| \leq (3/\delta)^{2d} \). Set next \( M_0(\rho) = \max \{ \langle x \otimes y | \rho | x \otimes y \rangle : x, y \in N_{d, \delta} \} \). Then, let \( x, y \in S_{\mathbb{C}^d} \) and \( \tilde{x}, \tilde{y} \in N_{d, \delta} \) be such that \( u = x - \tilde{x}, v = y - \tilde{y} \) satisfy \( \|u\|, \|v\| \leq \delta \), and observe that
\[ (x \otimes y | \rho | x \otimes y) = (\tilde{x} \otimes \tilde{y} | \rho | \tilde{x} \otimes \tilde{y}) + (\tilde{x} \otimes \tilde{y} | \rho | \tilde{x} \otimes v) + (\tilde{x} \otimes \tilde{y} | \rho | \tilde{v} \otimes y) + (\tilde{x} \otimes \tilde{y} | \rho | u \otimes y) + (u \otimes y | \rho | x \otimes y) . \]

Hence, \( (x \otimes y | \rho | x \otimes y) \leq M_0(\rho) + 4\delta M(\rho) \), so that taking supremum over \( x, y \in S_{\mathbb{C}^d} \) yields \( M_0(\rho) \geq (1 - 4\delta) M(\rho) \). Yet, we know from Lemma [7] that, for fixed \( x, y \in S_{\mathbb{C}^d} \),
\[ \forall t > 0, \mathbb{P} \left( (\sqrt{(x \otimes y | \rho | x \otimes y)}) > \frac{1 + t/8}{d} \right) \leq e^{-c t^2} . \]

We therefore get by the union bound that
\[ \mathbb{P} \left( \sqrt{M_0(\rho)} > \frac{1 + t/8}{d} \right) \leq \left( \frac{3}{\delta} \right)^{4d} e^{-c t^2} . \]

Consequently, we eventually obtain, choosing \( \delta = t/10 \), in order to have \( 1 + t/4 \sqrt{1 - 4\delta} \geq 1 + t/4 - 5\delta/4 = 1 + t/8 \), that
\[ \mathbb{P} \left( \sqrt{M(\rho)} > \frac{1 + t/4}{d} \right) \leq \mathbb{P} \left( \sqrt{M_0(\rho)} > \frac{1 + t/8}{d} \right) \leq \left( \frac{30}{7} \right)^{4d} e^{-c t^2} . \]

And whenever \( s \geq Cd \log(1/t)/t^2 \), the r.h.s. of inequality (A8) above is smaller than \( e^{-c t^2} \).

So combining the deviation probabilities (A7) and (A8) with inequality (A6), we get precisely the announced result, just observing that \( e^{-c t^2} + e^{-c d^2 d^2 / \log^2 d} \leq e^{-c \ln^3 d} \). \qed
APPENDIX B: DIMENSION-DEPENDENT MONOGAMY RELATIONS FOR THE ENTANGLEMENT OF FORMATION AND THE REGULARIZED RELATIVE ENTROPY OF ENTANGLEMENT

Theorem 15. For any state $σ_{ABC}$ on $ℋ_A ⊗ ℋ_B ⊗ ℋ_C$ and any $η, η' > 0$, we have, setting $d_{AB} = \min(d_A, d_B)$ and $d_{AC} = \min(d_A, d_C)$,

$$E_F(σ_{ABC}) ≥ \max \left( E_F(σ_{AB}) + \frac{c}{d_A d_C \log^{4+η} d_{AC}} E_F(σ_{AC}) \right)^{4+η},$$

$$E_∞^R(σ_{ABC}) ≥ \max \left( E_∞^R(σ_{AB}) + \frac{c'}{d_A d_C \log^{4+η} d_{AC}} E_∞^R(σ_{AC}) \right)^{2+η'}. $$

where $c, c' > 0$ are constants depending on $η, η'$. 

Remark 16. For concreteness, in the main text we choose $η = 4$ and $η' = 2$.

To prove Theorem 15, we will need as a starting point the two monogamy-like relations appearing in Lemma [17] below. In the latter, we denote by $E_{R,LOCC}$ the relative entropy of entanglement filtered by one-way LOCC measurements, and by $E_{R,LOCC}^∞$ its regularized version. These were introduced and studied in [50], to which the reader is referred for more details.

Lemma 17. For any state $σ_{ABC}$ on $ℋ_A ⊗ ℋ_B ⊗ ℋ_C$, we have

$$E_F(σ_{ABC}) ≥ E_F(σ_{AB}) + E_{R,LOCC}(σ_{AC}) \quad \text{and} \quad E_∞^R(σ_{ABC}) ≥ E_∞^R(σ_{AB}) + E_{R,LOCC}^∞(σ_{AC}).$$

Proof. The second inequality in (B1) was proved in [56, Lemma 2]. So let us turn to proving the first inequality in (B1).

For this, assume that $p_i, ψ_i^A |BC$ is such that $σ_{ABC} = \sum p_i ψ_i^A |BC$ and $E_F(σ_{ABC}) = \sum p_i E_F(ψ_i^A |BC)$. Now, for a pure state $ψ_{ABC}$, denoting by $σ_{AB}$ and $σ_{AC}$ its reduced states on $ℋ_A ⊗ ℋ_B$ and $ℋ_A ⊗ ℋ_C$ respectively, we know from [28, Cor. 2], that $E_F(ψ_{ABC}) = E_F(σ_{AB}) + S_{LOCC}(σ_{AC} | σ_A ⊗ σ_C)$. Hence,

$$E_F(σ_{ABC}) = \sum p_i E_F(σ_i^A |BC) + S_{LOCC}(σ_{AC} | σ_A ⊗ σ_C) ≥ E_F(σ_{AB}) + S_{LOCC}(σ_{AC} | σ_A ⊗ σ_C),$$

where the inequality follows from the convexity of $E_F$ and the joint convexity of $S_{LOCC}$, combined with the observation that $\sum_i p_i σ_i^A = σ_{AB}$ and $\sum_i p_i σ_i^A = σ_{AC}$. Now, the state $\sum_i p_i σ_i^A ⊗ σ_i^C$ is obviously separable across the cut $ℋ_A : ℋ_C$, and therefore $S_{LOCC}(σ_{AC} | σ_A ⊗ σ_C) ≥ E_{R,LOCC}(σ_{AC})$, which yields precisely the advertised result.

Proof of Theorem 15. Since we can exchange the roles played by $ℋ_B$ and $ℋ_C$, we just have to show that

$$E_F(σ_{ABC}) ≥ E_F(σ_{AB}) + \frac{c}{d_A d_C \log^{4+η} \min(d_A, d_C)} E_F(σ_{AC})^{4+η},$$

$$E_∞^R(σ_{ABC}) ≥ E_∞^R(σ_{AB}) + \frac{c'}{d_A d_C \log^{4+η} \min(d_A, d_C)} E_∞^R(σ_{AC})^{2+η'}. $$

By Pinsker inequality and the Pinsker-type inequality established in [56, Lemma 3], we know that, for any state $σ_{AC}$,

$$E_{R,LOCC}(σ_{AC}) ≥ \frac{1}{2 \ln 2} ||σ_{AC} - S(ℋ_A : ℋ_C)||^2_{LOCC} \quad \text{and} \quad E_{R,LOCC}^∞(σ_{AC}) ≥ \frac{1}{8 \ln 2} ||σ_{AC} - S(ℋ_A : ℋ_C)||^2_{LOCC}. $$

Now, we also know from [57] that, for any states $σ_{AC}$ and $σ'_{AC}$,

$$||σ_{AC} - σ'_{AC}||_{LOCC} ≥ \frac{c_0}{\sqrt{d_A d_C}} ||σ_{AC} - σ'_{AC}||_1.$$

And finally, it was shown in [58, Corollaries 4 and 7], that for any states $σ_{AC}$ and $σ'_{AC}$, and any $η, η' > 0$

$$|E_F(σ_{AC}) - E_F(σ'_{AC})| ≤ C \log \left( \min(d_A, d_C) \right) ||σ_{AC} - σ'_{AC}||_1^{1/2 - η},$$

$$|E_∞^R(σ_{AC}) - E_∞^R(σ'_{AC})| ≤ C' \log \left( \min(d_A, d_C) \right) ||σ_{AC} - σ'_{AC}||_1^{1 - η'}.$$
So putting everything together, we get that, for any state $\rho_{AC}$,

$$E_{R,\text{LOCC}^-}(\rho_{AC}) \geq \frac{c}{d_{A}d_{C} \log^{3+\eta}[\min(d_{A}, d_{C})]}[E_{F}(\rho_{AC})]^{3+\eta},$$

$$E_{R,\text{LOCC}^-}^{\infty}(\rho_{AC}) \geq \frac{c'}{d_{A}d_{C} \log^{3+\eta}[\min(d_{A}, d_{C})]}[E_{F}^{\infty}(\rho_{AC})]^{2+\eta'}.$$

And combining these two lower-bounds with Lemma 17 yields, as wanted, the two inequalities (B2) and (B3). $\square$
