Abstract

Background

Sexually transmitted infections (STIs) are mainly transmitted by sexual contact or similar sexual contact, which can cause diseases of genitourinary organs, accessory lymphatic system and major organs of the whole body. STIs include clinically symptomatic diseases and asymptomatic infections. The World Health Organization (WHO) reports that more than 1 million sexually transmitted infections (STIs) are acquired every day worldwide. By analyzing the temporal trend of the sexually transmitted infections incidence in China in the past 20 years, we can provide a scientific basis for the further development of prevention and control measures related to sexually transmitted infections.

Methods

Joinpoint regression model is used to fit the incidence data of three sexually transmitted diseases in China from 1999 to 2018. Annual percentage change (APC) and Average annual percentage Change (AAPC) are calculated to evaluate the temporal trend changes of the incidence of three major sexually transmitted diseases.

Results

The overall incidence of AIDS/HIV has been on the rise for 20 years, rising by an average of 33.7% per year ($P < 0.05$). The most obvious increase is in 2002–2005, an average annual increase of 102.5%. The overall incidence of gonorrhea is on a downward trend, decreasing by 4.9% per year on average ($P < 0.05$). However, its incidence shows a slow rising trend from 2012 to 2018, with an average annual increase of 6.0%. The overall incidence of syphilis is also on the rise, increasing by an average of 9.1% per year ($P < 0.05$). Except 1999–2003, the incidence of syphilis shows a downward trend, and the other time stages shows a significant upward trend.

Conclusions

In the past 20 years, the corresponding measures have been taken in China for sexually transmitted infections and achieved remarkable results, but the three major sexually transmitted infections are still in the forefront of the reported notifiable infectious diseases incidence in China. At the same time, all sexually transmitted infections are beginning to shift from high-risk population to the general population, especially adolescents and the floating population. Therefore, China should still pay more attention to the prevention and control of STIs to hold back their further spread or epidemic.

Background
Sexually transmitted infections (STIs) STIs are mainly transmitted by sexual contact or similar sexual contact, which can cause diseases of genitourinary organs, accessory lymphatic system and major organs of the whole body. STIs include clinically symptomatic diseases and asymptomatic infections. The World Health Organization (WHO) reports that More than 1 million sexually transmitted infections (STIs) are acquired every day worldwide[1]. Most STIs have no symptoms or only mild symptoms that may not be identified as STIs. In some cases, STIs can not only harm the patients, but can also lead to stillbirth, neonatal death, low birth weight and premature birth, sepsis, pneumonia, neonatal conjunctivitis and even congenital malformations through mother-to-child transmission. Thus it can be seen that STIs is a worldwide social and public health problem, and is one of the main diseases harmful to people's reproductive health.

The JoinPoint regression model, also known as fragment regression, was proposed by Kim in 2000[2]. The basic idea is to divide a long-term liner trend into several segments, each of which is described by a continuous linear pattern. It mainly includes two models: linear data model and logarithmic linear data model. The former is mainly used for the data of dependent variables following normal distribution or approximate normal distribution, while the latter is used for the data of dependent variables obeying Poisson distribution or exponential distribution. Because the JoinPoint regression model does not have strict requirements on whether there is a trend in the data itself, which is often used to study the epidemiological trends in cancer and chronic diseases[3–5].

Currently, no studies have used the JoinPoint regression model to analyze the incidence trends of major sexually transmitted infections in China over the past 20 years. The purpose of this study is to analyze the temporal trend changes of the incidence of sexually transmitted infections (STIs) through the Jointpoint regression model, so as to provide a basis for the further development of prevention and intervention measures related to STIs and control the further epidemic of STIs in China.

**Methods**

**Data sources**

The data are obtained from the incidence data of HIV/AIDS, syphilis and gonorrhea in the Chinese Health Statistics Yearbook (2003-2019)[6]. The data unit is 1/100,000. (Table 1)

**Table 1 Incidence of HIV, syphilis, gonorrhea in China in 1999-2018**
| year | Incidence of AIDS (1/100,000) | Incidence of syphilis (1/100,000) | Incidence of gonorrhea (1/100,000) |
|------|-----------------------------|----------------------------------|----------------------------------|
| 1999 | 0.02                        | 6.50                             | 27.54                            |
| 2000 | 0.02                        | 6.43                             | 22.92                            |
| 2001 | 0.04                        | 6.11                             | 18.57                            |
| 2002 | 0.06                        | 5.80                             | 16.14                            |
| 2003 | 0.08                        | 5.63                             | 16.54                            |
| 2004 | 0.23                        | 7.70                             | 17.71                            |
| 2005 | 0.43                        | 10.96                            | 14.27                            |
| 2006 | 0.60                        | 14.24                            | 12.46                            |
| 2007 | 0.82                        | 17.16                            | 11.33                            |
| 2008 | 1.10                        | 21.06                            | 10.16                            |
| 2009 | 1.51                        | 24.66                            | 9.19                             |
| 2010 | 2.56                        | 28.90                            | 8.07                             |
| 2011 | 2.92                        | 32.04                            | 7.61                             |
| 2012 | 3.11                        | 33.30                            | 7.07                             |
| 2013 | 3.12                        | 32.86                            | 7.61                             |
| 2014 | 3.33                        | 30.93                            | 7.05                             |
| 2015 | 3.69                        | 31.85                            | 7.36                             |
| 2016 | 3.97                        | 31.97                            | 8.39                             |
| 2017 | 4.15                        | 34.49                            | 10.06                            |
| 2018 | 4.62                        | 35.63                            | 9.59                             |

**Basic index**

Due to the absence of morbidity and mortality data in some years in the yearbook, only complete morbidity data of three STIs are used in this study.

**Joinpoint regression analysis**

The data analysis is performed using the Joinpoint Regression Software (4.8.1.0 version developed by the American cancer research center). The software can analyze and fit the data on the incidence of three
sexually transmitted infections by logarithmic linear model. The number, location and the corresponding
$P$ value of the connection points were determined by the monte carlo permutation test[2, 4]. Since the
number of observed values is only 20, the default number of connection points in the software is at most
3. $P<0.05$ was statistically significant.

The Joinpoint regression model is used to fit the incidence of HIV/AIDS, syphilis and gonorrhea
respectively, and annual percent Change (APC) and average annual Percent Change (AAPC) are
calculated to evaluate the temporal trend changes of the incidence of the three major sexually
transmitted infections (STIs) in China from 1999 to 2018. The model will be fitted to analyze the change
of three STIs in different years. If APC<0, indicating that the incidence rate is decreasing year by year; If
APC>0, meaning that the incidence of disease decreases year by year; If APC=AAPC, indicating no
connection points and this group of data increases monotonously or decreases monotonously with the
change of the years.

Results

Trend analysis of AIDS/HIV incidence

As can be seen from Figure 1, the temporal trend changes of AIDS/HIV incidence have three connection
points from 1999 to 2018. They are in 2002, 2005 and 2011 respectively. The overall incidence of AIDS
has been on the rise for 20 years, rising by an average of 33.7% per year ($P<0.05$). From 1999 to 2002,
The APC shows a slowly rising trend, with 42.6%; And a rapid upward trend in 2002-2005, APC is up to
102.5%; But there is a slow upward trend again in 2005-2011, APC is 38.2%; At the same time, the upward
trend from 2011 to 2018 further slow down, APC is 5.7% (Table 2).

| year         | APC/%   | AAPC/%  |
|--------------|---------|---------|
| 1999-2002    | 42.62*  | 33.7*   |
| 2002-2005    | 102.52* |         |
| 2005-2011    | 38.25*  |         |
| 2011-2018    | 5.74*   |         |

* $P<0.05$

Trend analysis of gonorrhea incidence

The results of gonorrhea incidence are shown in Figure 2. The temporal trend changes of gonorrhea
incidence from 1999 to 2018 have only 1 connection point, which is in 2012. The overall incidence of
gonorrhea has been declining for 20 years, by an average of 4.9% per year($P<0.05$). From 1999 to 2012,
there is a rapid downward trend, with APC of -9.6%; However, it shows a slow upward trend from 2012 to 2018, with APC of 6.0%(Table 3).

**Table 3 APC and AAPC of gonorrhea incidence in Chinese population, 1999-2018**

| year    | APC/%  | AAPC/% |
|---------|--------|--------|
| 1999-2012 | -9.57* | -4.9*  |
| 2012-2018 | 5.96*  |        |

* $P<0.05$

**Trend analysis of syphilis incidence**

As shown in Figure 3, there are 3 connection points in the temporal trend changes of syphilis incidence from 1999 to 2018, and the number of connection points is consistent with HIV/AIDS, respectively in 2003, 2006 and 2010. The overall incidence of syphilis shows an upward trend, with an average annual increase of 9.1% ($P<0.0001$). The APC shows a downward trend from 1999 to 2003, which is -3.6%; From 2003 to 2006, there is an upward trend, with APC of 36.6%; Although the two time periods of 2006-2010 and 2010-2018 remain on the rise, APC is 20.3% and 1.7% respectively, which is significantly lower than that in 2003-2006(Table 4).

**Table 4 APC and AAPC of syphilis incidence in Chinese population, 1999-2018**

| year    | APC/%  | AAPC/% |
|---------|--------|--------|
| 1999-2003 | -3.65* | 9.1*   |
| 2003-2006 | 36.62* |        |
| 2006-2010 | 20.33* |        |
| 2010-2018 | 1.68*  |        |

* $P<0.05$

**Discussion**

The results of this study show that the incidence of AIDS/HIV in Chinese population increased year by year from 1999 to 2018, which are consistent with the results of Yong-Chao and Zunyou Wu's study[7, 8]. The rising tendency of morbidity is most pronounced during the period of 2002-2005, the average annual increase was 102.5%. The possible reasons are the abuse of intravenous drug, the increase in the number of homosexual men and infection occurred after irregular blood collection in this time stage[9]. However, since the implementation of the blood donation law in 1998, the transmission of HIV through blood collection and supply has been basically controlled in China. At present, the transmission of HIV is
mainly through sexual transmission[10, 11]. The introduction of "four exemptions and one care" policy in 2006 and the implementation of the "six expansion and five strengthening" prevention and control measures in 2011 have also effectively slowed down the rising tendency of AIDS incidence, which is consistent with the results of our study[12-14]. At the same time, a research report on the global AIDS epidemic shows that compared with other countries, the current AIDS epidemic in China is at a low epidemic level[15]. But the relevant studies indicate that the AIDS infected people in China are changing from high-risk population to general population, especially adolescents and the floating population [7, 16]. Adolescents not only have a high incidence of premarital sex but also have multiple sexual partners, leading to a high incidence of sexually transmitted infections among adolescents. According to the survey, 1 out of 7 new HIV infections in the world now occur in adolescence, AIDS has become the second leading cause of death among adolescents worldwide[16]. At the same time, due to the low education level of the floating population, their knowledge, attitudes and behaviors of HIV are limited, and their strong mobility leads to the floating population becoming a bridge for the spread of HIV[9, 17]. Therefore, in order to prevent the epidemic of AIDS in the general population, our country should strengthen the sex education, health promotion and health education for the two groups of teenagers and floating population.

Gonorrhea is reported to be the most common sexually transmitted infection in any country in the world[18, 19], with 106 million new cases of gonorrhea in adults worldwide each year and extremely high exposure rates. Not only is it a major cause of pelvic inflammatory disease and infertility in women, it can also increase the sexual transmission and prevalence of HIV. Therefore, the gonorrhea has a significant impact on reproductive health. The epidemic of gonorrhea in China rose rapidly in the 1970s, reached its peak in 1999, and then declined, which is consistent with the results of our study[20]. But our study shows that the incidence of gonorrhea showed a significant decrease in 1999-2012, and then showed a significant increase from 2012 to 2018. The increased trend of the gonorrhea incidence in China from 2012 to 2018 is similar to that of the United States and the United Kingdom in the same years[21]. An increase of the gonorrhea incidence at this time stage in China may be due to the expanded coverage of gonorrhea screening, the increased sensitivity of diagnostic methods and the increase in the number of MSM patients[22, 23]. Although this study indicates that the incidence of gonorrhea in China from 1999 to 2018 shows an overall trend of decline, it is still in the forefront of the notifiable infectious diseases. Especially in 2018 its incidence is 9.58%, ranking fourth[6]. Gonorrhea is currently treated with antibiotics because there is no vaccine that can be prevented. However, neisseria gonorrhoeae has been found to be increasingly resistant to many antibiotics, making the treatment of gonorrhea become a major challenge for clinicians in recent years[11, 19, 24, 25]. Therefore, in order to control the rising trend of gonorrhea epidemic in China, the state not only needs to actively publicize the knowledge related to gonorrhea among high-risk population, so as to enhance the public awareness of prevention and treatment of gonorrhea, but also needs to increase the research and development of gonorrhea related vaccines and drugs.

According to the reports of WHO, 988 000 pregnant women were infected with syphilis in 2016, resulting in over 350 000 adverse birth outcomes including 200 000 stillbirths and newborn deaths[26]. It can be
seen that syphilis seriously affects the life and health of women who are in childbearing age and of newborns[27]. The results of our study show that the incidence of syphilis in China is on the rise from 1999 to 2018 on the whole, which is contrary to the overall temporal trend of gonorrhea incidence[20]. The trends in the incidence of both sexually transmitted diseases are similar to developed countries. On the one hand, this phenomenon may be due to the increased number of syphilis infection population in MSM of China; On the other hand, it may be because the Government launched a national plan on expanding syphilis screening in 2010, which led to an increase in the number of cases diagnosed as latent syphilis[28, 29]. And the related literature also suggest that syphilis infection rate is higher than AIDS in Chinese MSM population [7]. From the four temporal stages of syphilis incidence, we can learn that syphilis incidence has a downward trend from 1999 to 2003, the rest of time stages presents a steady upward trend. It also suggests that China should pay more attention to the prevention and treatment of syphilis. At the same time, the relevant studies have shown that the majority of Chinese people's knowledge of syphilis is far lower than the standard of 10-year plan set by the our country, which requires the awareness rate of the general population reaches 90% and that of high-risk population reaches 95% by 2020[27, 28, 30]. Therefore, the country should strengthen the publicity of syphilis prevention knowledge, enhance the prevention and control ability and prevent its further spread.

Conclusion

To sum up, our country has taken corresponding prevention and control measures for AIDS, gonorrhea, syphilis and other sexually transmitted diseases, and achieved good results in the past 20 years. But the Chinese Health Statistics Yearbook (2019) shows that the incidence of three kinds of sexually transmitted infections is still in the forefront of the notifiable infectious diseases[6]. At the same time, the precocious puberty of teenagers generally leads to the increase in the proportion of premarital sex. In addition, most teenagers have multiple sexual partners, These factors lead to teenagers become the high-risk population of sexually transmitted infections[16]. Therefore, the prevention and control of sexually transmitted infections (STIs) in China needs to provide widely recognized effective prevention, screening, diagnosis and treatment interventions for centers for Disease Control and Prevention and hospitals at all levels. In addition, it is necessary to actively popularize knowledge related to gonorrhea and syphilis, and carry out large-scale peer education[31], so as to further reduce the spread or epidemic of sexually transmitted infections in China.

**Figures**
Figure 1

Time trend of AIDS/HIV incidence in Chinese population, 1999-2018. * indicates that the Annual Percent Change (APC) is significantly different from zero at the alpha=0.05 level. Final selected model: 3 joinpoints.
Figure 2

Time trend of gonorrhea incidence in Chinese population, 1999-2018. * indicates that the Annual Percent Change (APC) is significantly different from zero at the alpha=0.05 level. Final selected model: 2 joinpoints.
Figure 3

Time trend of syphilis incidence in Chinese population, 1999-2018. * indicates that the Annual Percent Change (APC) is significantly different from zero at the alpha=0.05 level. Final selected model: 4 joinpoints.
